efficiency ( $nO$ ). The purpose of this study was to identify relationships between muscle coordination patterns and factors affecting muscle coordination to explain changes in  $nO$ . METHODS Surface electromyography (EMG) was measured from 10 leg muscles in 9 competitive cyclists at a range of workloads. The EMG was resolved into intensities (IEMG) (von Tscharnner, 2000). Total EMG intensity (Itot) was given by the sum of IEMG across all muscles for each pedal cycle and was used as a proxy for metabolic power (Wakeling et al., 2011). The ratio of mechanical power output to Itot was therefore used to estimate  $nO$ . Kinematics, pedal forces and power output were also measured and principal component (PC) analysis was used to establish muscle coordination (IPC), kinematic and pedal force patterns (Wakeling et al., 2009). Relationships between the IPCs and the pedal forces, kinematics, power output and  $nO$  were determined. RESULTS AND DISCUSSION The rectus femoris and tibialis anterior were keys to power production early in the pedal cycle and the soleus was critical in the bottom of the cycle. The gluteus maximus had the largest IEMG range supporting its role as a major contributor to high power output (Ryan et al., 1992). The  $nO$  was maximized at 55-60%  $VO_{2max}$  and was strongly related to the muscle coordination patterns. High  $nO$  had an even distribution of IEMG across all muscles with equally dispersed timing among the key power producers. Pedal forces were consistent among cyclists and  $nO$  was independent of the direction of applied force. The ankle angles changed with power output, Itot and  $nO$ . The hip angles varied with power output and Itot but not with  $nO$ . The knee angles were similar throughout. This study demonstrates that  $nO$  in cycling is achieved through coordinated contraction of muscles crossing the same joint, sequential peak muscle activation from knee to hip to ankle and a reliance on multiple muscles to produce large joint torques. The results may have implications on training for cycling as training at 55-60%  $VO_{2max}$  may maximize the rider's exposure to high-efficiency coordination patterns and kinematics. REFERENCES 1. ### **PATELLAR TENDON CROSS SECTIONAL AREA AND MOMENT ARM USING THREE-DIMENSIONAL MRI IN PATIENTS WITH ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION.**

KARAGIANNIDIS, E., KELLIS, E.

ARISTOTLE UNIVERSITY OF THESSALONIKI

Introduction Surgical reconstruction of a torn anterior cruciate ligament (ACL) is performed using various types of grafts. One of the most commonly used autografts is the bone-patellar tendon-bone (BPTB) graft, which has lead to very successful clinical outcomes in ACL reconstruction (Busam et al., 2008). Most studies have shown that the thickness of the patellar tendon after harvesting increases, at least up to 2 years postoperatively (Bernicker, 1998, Kartus, 1999). However, whether this structural change in PT properties affects muscle moment-arms is unknown. The purpose of this study was to examine whether 3-D anatomical cross-sectional area (aCSA) of the patellar tendon (PT) and moment arm in individuals who had ACL reconstruction differs compared with controls. Methods Eight males and two females ( $n=10$ ) with a mean age of 42 years (SD 5.5 yr), height 1.74 (SD 3.14 cm), tibial length 39.2 (SD1.84 cm) and femur length 41 (SD 1.13 cm) participated in the study. The knee joint was scanned using MRI, the Femur (FM), Tibia (TB), PT and PT tendon were identified in each MRI plane and reconstructed in 3-D using 3-D Doctor. An adopted form of tibiofemoral contact point (TFCP) was used in order to measure PT moment arm in 3-D images. Tendon CSA was measured at 10% 25%, 50% and 75% of the tendon length by the use of MRI axial planes. Variables were correlated for ACL reconstructed and controls. Results The PT tendon moment arm evaluated to 49.63 mm (SD 5.30) for controls and 49.67mm (SD 4.7) for ACL reconstructed patients. T-tests showed non-statistical significant differences between healthy and ACL-reconstructed values in both PT moment-arm and a CSAs ( $t= .010$   $p= .992$ ) Discussion The present study showed that PT tendon moment arm is not affected by harvesting for ACL reconstruction, despite evidence from other studies that tendon is hypertrophic for some period after surgery. These findings must be taken into account on future 3-D biomechanical research with reconstructed models and in more precise measurement on knee biomechanics. References Busam, M. L., Provencher, M. ### **EFFECTS OF ISOMETRIC TRAINING ON THE MOMENT-ANGLE RELATIONSHIP AND MUSCLE ARCHITECTURE OF KNEE EXTENSORS**

ALEGRE, L.M., RODRIGUEZ-CASARES, R., FERRI-MORALES, A., AGUADO, X.

UNIVERSITY OF CASTILLA-LA MANCHA

Introduction The force-length relationship of the skeletal muscle can be modified by resistance training (2,4), and has been related to decreased risk of muscle injury when the peak torque is shifted to longer muscle lengths (3). However, the mechanisms that underpin these processes are not still clear. The aim of this study was to analyse the muscle adaptations produced by two protocols of isometric training: one at long muscle lengths and another at short muscle lengths. Methods Twenty-nine men and women were divided into three groups: one performed isometric training of the knee extensors at long muscle lengths during 8 weeks (80% of MVC, 90° knee angle, G90, 0° = full extension), and the second one performed the same training protocol at short muscle lengths (50°, G50). The subjects of the third group acted as controls. Before and after the training programme muscle isokinetic dynamometry (60°•s<sup>-1</sup>) was utilised to analyse the moment-angle relationship, and isometric (90° knee flexion) strength was tested. Besides, we also measured vastus lateralis (VL) muscle architecture with ultrasonography. Results There was a shift in the angle of peak torque of the G90 to longer muscle lengths (80.9° pre-training and 90.3° post-training,  $P=0.002$ ), while the G50 angle shifted to shorter muscle lengths (from 76.6° to 70.3°,  $P=0.039$ ). There were also increases in isometric strength in both training groups, (33%,  $P=0.000$  vs 14%,  $P=0.017$ ; G90 and G50, respectively). Both training groups showed significant increases in muscle thickness, (14%,  $P=0.001$  vs. 5%,  $P=0.027$ ; G90 and G50, respectively) but only G90 significantly increased their pennation angles. Besides, the G90 showed a tendency to increase their fascicle length (3%, ns), while the G50 fascicle lengths remained unchanged (-1%, ns). Discussion The results of the present study show changes in muscle architecture along with shifts in the angle-torque relationship of knee extensor muscles after isometric training at long and short muscle lengths. VL muscle fascicles tended to increase in the group that trained at long muscle lengths, while showed no changes with the isometric training at short muscle lengths. We think that the greater strength gains and the architectural changes showed with training at long muscle lengths were related to the greater stress and strain imposed on the muscle fascicles at this joint configuration (1,2). ## JOINT POWER CONTRIBUTIONS TO EXTERNAL POWER OUTPUT ON DIFFERENT ERGOMETER CONFIGURATIONS IN ELITE MALE ROWING

GREENE, A., SMITH, R., SINCLAIR, P., DICKSON, M., COLLOD, F.

UNIVERSITY OF SYDNEY

JOINT POWER CONTRIBUTIONS TO EXTERNAL POWER OUTPUT ON DIFFERENT ERGOMETER CONFIGURATIONS IN ELITE MALE ROWING  
Greene, A.I, Smith, R.I, Sinclair, P.I, Dickson, M.I and Colloud, F.Z. 1: University of Sydney (Sydney, Australia), 2: University of Poitiers (Poitiers, France) Introduction Rowing ergometers form an integral part of the training regime of all rowers, regardless of experience or performance level. However, owing to the differing designs of rowing ergometers there exists some dispute as to how different ergometers compare in regard to the technical and force parameters of the rowing stroke. Whether the foot stretcher is fixed or free to move in the anterior posterior direction may dictate the rower's movement patterns and effect power production and joint coordination through the stroke. This may ultimately affect the potential of the ergometer to best replicate on-water rowing. Method Rowers (14) were tested at 32 strokes/minute on three ergometer conditions: the fixed stretcher Concept2 ergometer, the Concept2 ergometer mounted on sliding rails and the sliding stretcher RowPerfect ergometer. Ergometers were instrumented identically to measure the external force generated at the handle and the foot stretcher, and reflective markers (52) were attached to specific anatomical landmarks on the subject to record the 3D kinematics of the rowing stroke. A nine segment inverse dynamics model was used to calculate joint and overall power delivery. Results Peak power generation and absorption at the knee joint was significantly greater on the fixed stretcher when compared to the sliding stretcher ergometers ( $p = 0.01$ ). Joint energy production at the knee and hip joints was significantly greater for the fixed stretcher ergometer condition ( $p = 0.044$ ;  $p = 0.025$ ), however no differences were found between ergometer conditions for the external energy delivered to the ergometer by the rower. Discussion Whilst rowing at the same stroke rate and intensity, the fixed stretcher ergometer increases the flexor and extensor moments, and subsequently the power generation and absorption at the knee joint. Greater power is generated at the knee joint to enable sufficient power to be delivered to the ergometer in order to accelerate the entire rowers mass relative to a fixed point. The fixed stretcher also acts to change the coordination pattern of the rower during the recovery phase by changing the timing and increasing periods of knee power generation and absorption. Joint energy requirements at the knee and hip joints increased on the fixed stretcher ergometer, however this increased joint energy production was not delivered directly to the to the ergometer, suggesting reduced mechanical efficiency when rowing the fixed stretcher ergometer. The presence of the sliding foot stretcher may provide a more accurate portrayal of on-water rowing stroke mechanics than the fixed stretcher ergometer, which increases the workload and demands of the joints of the lower limb.

### IS-SH11 Emotion in Sport

#### EMOTIONS IN SPORT: CURRENT ISSUES & PERSPECTIVES

HANIN, Y.

KIHU - RESEARCH INSTITUTE FOR OLYMPIC SPORTS, JYVÄSKYLÄ

Introduction This presentation reviews the selected issues in research on emotion-performance relationships in high-achievement sport. An individualized and evidence-based approach (termed the Individual Zones of Optimal Functioning: IZOF model) was used to examine state-like performance-related emotional experiences & meta-experience with a special emphasis on their defining characteristics (Hanin, 2000, 2007, 2009, 2010). Methods In the IZOF-based assessments, it is assumed that athletes are able to generate their own words to describe their unique emotional experiences (Hanin, 2000, 2007). Emotion profiling involves recalled, current, anticipatory, optimal/dysfunctional, interpersonal and intra-group measures. We also used an aggregated 40 items Emotional State Profile (ESP-40, Hanin, 2010) to identify interaction patterns of optimal and dysfunctional emotions (positively-toned and negatively-toned). The Identification-Control-Correction (ICC) procedure (Hanin & Hanina, 2009) creates an action-profile (a movement sequence) by assessing an athlete's self-generated components of the task execution process. Results and discussion The findings provide empirical support for the benefits of idiographic approach to emotions in high-achievement sport. Several developments include the issues of multidimensionality for the system description of idiosyncratic emotional experiences, the categorization of emotion content, the in-out of the zone concept in prediction of individually successful and poor performances, and optimal and dysfunctional emotion intensity. The biggest barrier in research on performance-related emotions is a lack of performance process measures usually limited to normative performance outcomes. Thus similar to assessments of idiosyncratic emotions, the ICC programme is proposed as individualized self-referenced action profiling. Conclusion Future research may focus on interaction patterns of athletes' emotional experiences and on the development of action-profiling and performance process measures. This would enable to identify individually optimal and dysfunctional movement sequences and to combine emotion-centered and action-centered coping strategies in regulation of performance-related psychobiosocial states. #### EMOTION AND PERFORMANCE IN SPORT AND PHYSICAL ACTIVITY: A HOLISTIC APPROACH

ROBAZZA, C.

UNIVERSITÀ DI CHIETI

Introduction The multifaceted relationships among emotional states and performance in sport and physical activity have been studied in light of the holistic conceptualisation of the Individual Zones of Optimal Functioning (IZOF) (Hanin, 2007). According to the IZOF model, each performer experiences a specific content and intensity range of positively and negatively toned psychobiosocial (PSB) states that can

have either a functional or dysfunctional impact on performance. The interaction between emotional states and performance is dynamic and bidirectional; namely, emotions tend to influence performance, while on-going performance outcomes influence the content and intensity of emotions. Methods Several IZOF-based studies recently have been conducted to examine the emotion-performance link (e.g., Pellizzari et al., in press), the effects of an action-oriented IZOF-based intervention on performance (Bortoli et al., 2011b), and the effects of a motivational climate on youngsters in the context of physical education and sport (e.g., Bortoli et al., 2011a). Results and discussion Performance findings showed that an individual's optimal pattern of emotional level was associated with optimal performance and, conversely, a dysfunctional pattern was related to poor performance; athletes also experienced optimal-pleasant emotions after good performances, and dysfunctional-unpleasant emotions after poor performances (Pellizzari et al., in press). In a further study, an action-oriented individualised intervention has been effectively applied to the Italian shooting team to help shooters improve, stabilise, and optimise their performances (Bortoli et al., 2011b). Physical activity findings showed task orientation and a perceived mastery-involving climate to be related to positively-toned PBS states, whereas performance climate to be related to negatively-toned PBS states (e.g., Bortoli et al., 2009). Moreover, perceived competence, actual competence, and task orientation were strong predictors of positively-toned PBS states (Bortoli et al., 2011a). Finally, performance climate and an antisocial moral atmosphere in sport were shown to be related to antisocial behaviour and a range of negatively-toned PBS states (Bortoli et al., 2011c). Conclusion Overall findings showed the advantages of adopting the IZOF-based holistic approach to the study of emotion-related states in sport and physical activity. ## ENHANCING EMOTION REGULATION OF OTHERS AND SELF IN SPORT

LANE, A.M.

*WOLVERHAMPTON UNIVERSITY*

Introduction Emotions are proposed to be energy giving and if people can harness their energy, then they can be helpful for performance (Hanin, 2000). Evidence shows that individuals develop meta-beliefs on which emotions help performance (Hanin, 2003). Emotion regulation activities are proposed to be driven by a discrepancy between current and ideal states (Carver, 2004). The aim of this presentation is to report on a series of studies designed to assess emotions associated with best and worst performance and the use and effectiveness of emotion regulation strategies used by athletes in a number of different sports. Methods Current and ideal emotions were assessed using both standardised and ideographic measures. Emotion regulation strategies were assessed using cognitive and behavioural strategies identified in the recently developed Emotion Regulation of Others and Self Scale (EROS). We also assessed emotional self-efficacy and trait emotional intelligence. Data are presented from over 2000 athletes using cross-sectional and longitudinal design from a range of sports. The results presented are a summary of these studies. Results Results show that athletes are motivated to increase emotions associated with high action-tendencies regardless of whether these are pleasantly-toned (i.e., excitement) or unpleasantly-toned (i.e., anger and/or anxiety). Athletes tend to seek to reduce the intensity of emotions such as depression and dejection. However, it should be noted that there are large intra-individual differences in the intensity of emotions associated with best performance. To increase unpleasant high-activation emotions, athletes use a range of cognitive and behavioural strategies. Examples include using negative self-talk or imagining feeling frustrated after being passed/defeated by a fellow competitor. However, athletes motivated to increase unpleasant emotions also use strategies to increase pleasant emotions, suggesting a dual process of increasing emotions with high action tendencies. We found that emotional intelligence self-efficacy is a predictor of the discrepancy between current and ideal emotions whereby the higher the self-efficacy, the smaller the discrepancy. This result suggests that emotionally intelligent athletes are capable of regulating emotions to optimal levels. Discussion We suggest that findings offer support for the notion that athletes hold beliefs that emotions such as anxiety and anger can be motivational (Hanin, 2000, 2003) and that athletes actively engage in strategies to increase these emotions. Findings also show that ideal emotional states comprise a mix of pleasant and unpleasant emotions typically associated with high action-tendencies. Trait emotional intelligence and emotional self-efficacy both offer an individual difference variable that predicts emotion regulation usage. Future research should look at the effectiveness of training packages designed enhance emotion regulation skills. References Carver, C. S. ### IS-BN10 Biomechanics of Non-steady state Locomotion

#### SIDE CUTTING MANOEUVRES IN SPORT: WHERE BALANCE AND INJURY RISK CONFRONT PERFORMANCE

VANRENTERGHEM, J.

*LIVERPOOL JOHN MOORES UNIVERSITY*

Sudden accelerations, decelerations, and changes of direction are key components of performance in field games. These manoeuvres induce large and often fatal stresses to the musculoskeletal system, in particular structures at the knee joint such as the anterior cruciate ligament and hamstring muscle (Hawkins et al, 2001). The last two decades has seen a substantial amount of work teasing out the interwoven roles of internal, environmental, and biomechanical risk factors of such injuries (Renstrom et al, 2008). Insight into the biomechanical risk factors has seen dramatic progress due to technological advances, looking in the detailed function of the knee joint in particular. Few authors have however focused on the role of whole-body balance in these contexts. In an attempt to better understand the role of balance, appropriate methods needed to be developed to evaluate balance in dynamic movements. The key requirement of these methods was that sufficiently accurate data for lower limb joint kinematics and kinetics needed to be available, while at the same time collecting whole body centre of mass (CoM) motion. The solution was found in measuring a lower limb and trunk (LLT) segmental model, including functional hip and knee joints. It was shown that without the need to model arms and head an accurate CoM could be estimated (Vanrenterghem et al, 2010). The acquired methodology has allowed us to revisit popular hypotheses concerning key risk factors of ACL and hamstring injury in a series of studies. In all of these studies we have looked at a 45 degree cutting manoeuvre from straight running. Amongst other questions, we addressed the roles of first half fatigue and half time recovery in football on ACL injury risk factors, and how this may interact with changed balancing abilities. We explored the role of balance in determining whole body motion

trajectories at different speeds of execution to revisit the role of approach speed on risk factors. We also revisited the proposed causal factors of increased joint stresses in unanticipated compared to anticipated side cutting manoeuvres. The advancement of work in this area is expected to benefit not only the understanding of injury risk in side cutting, but also hopefully aid to further the fundamental understanding of balance mechanisms in dynamic sports activities. ## NEUROMECHANICS OF WALK-TO-RUN TRANSITIONS

SEGERS, V., VAN CAEKENBERGHE, I., MALCOLM, P., AERTS, P., DE CLERCQ, D.

GHENT UNIVERSITY

Walking and running are two stable cyclic locomotion patterns with a different range of speeds. When increasing speed, the walk-to-run transition (WRT) spontaneously takes place. For the last decade we examined this type of unsteady locomotion from a biomechanical perspective. By studying the collective output of the system during WRT (e.g. kinematics, kinetics, EMG), insights in the control and execution of human unsteady locomotion can be gained. When humans spontaneously accelerate from standing still, the WRT-speed is 2.66 m/s and is very stable within and between individuals (De Smet et al., 2009a). The stability of the WRT-speed was also shown during accelerations on treadmill. Next we focused on how the actual WRT is realized. Based on kinesiology and mechanics of transitions during accelerations, we conclude that the WRT is a sudden event, accomplished during one step. This step starts from a double stance and ends with a flight phase. After a small preparation in the swing of the last walking step prior to WRT, during the transition step active power is generated by muscular input of the stance limb to initiate the first flight phase. It is uncertain how and at what level this energy input is controlled. We also examined why humans prefer this specific WRT-speed. Since the WRT-speed is likely not directly related to metabolic efficiency nor to the limits of the inverted pendulum mechanism, other proximate causes must trigger the transition. Dorsi- and plantar flexors were found to act at maximal or adverse conditions at WRT (Hreljac, 1995; Neptune & Sasaki, 2005). Indeed, resisting dorsi- and plantar flexors by means of a powered exoskeleton led to a lower WRT-speed (Malcolm et al., 2009a; 2009b). By manipulations of the weakest link, WRT-speed decreases. However, assisting the dorsi- and/or plantar flexors does not influence WRT-speed due to other weakest links. Furthermore, inducing a visual flow that is higher or lower than the actual speed (leading to an erroneous visual input in the perception-action cycle) also had an effect on WRT-speed (De Smet et al., 2009b). This unconscious influence of a misleading optic flow can probably be related to the coupling of visual flow to previous experience. We have to conclude that the full picture of the hierarchy and interplay between determinants of the WRT is not yet known. Moreover, conscious cognitive input (e.g. reaction on external stimulus) can overrule the signals of the peripheral neuromuscular triggers and the perception-action coupling. ## STABILITY IN WALKING AND RUNNING - BIOMECHANICAL CONCEPTS AND CHALLENGES

SEYFARTH, A.

INSTITUT OF SPORT SCIENCE, FSU JENA

In human walking and running, typical patterns of the ground reaction force with two humps in walking and a single hump in running are found. This behavior is widely found in nature and can be well described by assuming spring-like leg function (spring-mass model, Blickhan, 1989, extended to bipedal gaits, Geyer et al., 2006). However, systematic deviations from such a perfectly elastic leg behavior like a telescopic linear spring can be found. One reason for this is that the leg has non-elastic properties (e.g. in materials and muscles Haeufle et al., 2010). Also, the leg is landing at the ground with non-zero contact velocities leading to impact losses (De Wit et al., 2000). The segmental design of legs with a distal foot segment and almost straight knee configurations could also contribute to deviations in the spring-like leg function (Seyfarth et al., 2001, Maykranz, 2009). In fact, elastic properties at joint level are related to spring-like leg function in a nonlinear fashion (Rummel and Seyfarth, 2008). Furthermore, hip torques joint can redirect the leg force with respect to the center of mass (Maus et al., 2008). By this, the upper body can stay in an upright position guaranteeing postural trunk stability during locomotion. Another example of extending the spring-mass model is to include lateral body movements (Seipel and Holmes, 2005, Peuker and Seyfarth, 2010). In fact, even extensions to quadrupedal (Gross, 2009) and hexapod (Schmitt and Holmes, 2000) gait models can be considered. Interestingly, all these structural extensions of the model did preserve the previously observed self-stabilizing leg function found in the spring mass model (Seyfarth et al, 2001). With this repertoire of conceptual models it becomes possible to design models of desired complexity, which could inherit features of the underlying template models (Full & Koditschek, 1999). In order to compare the model predictions with experimental data it is important to make sure that the key characteristics of human gait are sufficiently represented in the biomechanical models. So far there are fundamental differences between the predicted gait pattern and experimental data on human locomotion. For instance, it is not clear which mechanisms cause the observed step-to-step variability in kinematic and kinetic parameters. This is important as concepts on gait and gait stability often rely on the assumption of a periodic gait pattern, which exhibits a fixed point. References Blickhan, 1989, J. Biomechanics. ## IS-PM15 Stem Cells and Tissue Regeneration in Muscle Physiology and Disease

## QUIESCENT AND ACTIVATED MUSCLE SATELLITE CELLS: TRANSCRIPTOME ANALYSIS AND MI-RNA REGULATION

BUCKINGHAM, M., CRIST, C., PALLAFACCHINA, G., MONTARRAS, D.

PASTEUR INSTITUTE, CNRS URA2578

The satellite cells of many muscles transcribe Pax3 as well as Pax7 and we have therefore used a Pax3GFP/+ mouse line to isolate these cells by FACS. When cultured, satellite cells undergo activation, however they repair damaged skeletal muscle less efficiently than freshly isolated cells. In vivo activated satellite cells are abundant in growing postnatal muscles and in regenerating adult mdx muscle. A transcriptome analysis was carried out in which satellite cells from adult muscle, which are mainly quiescent, were compared with cells from these sources of in vivo activated cells, where sequences common to both that undergo changes in level are probably associated with the activated state per se. Cultured cells had a strikingly different transcriptome profile. Aspects of this analysis will be discussed, that provide insight into the satellite cell niche. Many satellite cells already transcribe the myogenic determination gene, Myf5, and we detect no up-regulation of Myf5, nor indeed of MyoD on activation, although the proteins become detectable. We have shown miRNA-31 regulation of Myf5 mRNA through specific sites in the 3' UTR. We now report on the role of miRNA-31 in muscle satellite cells where it prevents premature differentiation, thus maintaining the quiescent satellite cell population required for regeneration. The rapid down-regulation of Pax3, required at the onset of differentiation, is also orchestrated by miRNA, in this case miRNA-27, that accumulates after satellite cell activation, prior to differentiation. Again interference with the activity of this microRNA interferes with differentiation and with regeneration in vivo.

## ADULT STEM CELLS IN MYOCARDIAL AGING AND REGENERATION

NADAL-GINARD, B.

LIVERPOOL JOHN MOORES UNIVERSITY

Cardiomyocyte death and renewal are the two sides of the proverbial coin of cardiac homeostasis in which the resident Cardiac Stem Cells (CSCs) play a central role (Ellison et al. 2007 Nature CPCM Suppl 1, S52). Although the generation of new cardiomyocytes predominates cell death in the young, contributing significantly to the normal growth of the heart into adulthood, cardiomyocyte death predominates the formation of new cardiomyocytes in late adulthood and old age (Anversa and Nadal-Ginard, 2002 Nature 415: 240). As the organism ages, the rate of cardiomyocyte death progressively rises, correlating with increases in the average size of the cardiomyocytes and the degree of cellular senescence. Myocardial aging results from senescence of cardiomyocytes due to attenuation in their turnover dictated by CSC aging and the inevitable accumulation of older cells, participating in the occurrence of ventricular dysfunction and failure in the 'old' heart (Torella et al. 2004 Circ Res 94:514). A goal of cardiovascular research for the past decade has been to find a method of replacing the cardiomyocytes lost through ageing and/or one or more myocardial infarctions, so as to prevent, or reverse, the pathological remodelling of the myocardium that is responsible for the development of late cardiac failure. Stem cell therapy is fast becoming an attractive and highly promising treatment for heart disease and failure. Current clinical trials are mainly using bone marrow cells of different origins as the therapeutic agent (Nadal-Ginard & Vuster, 2007, Nature CPCM 4:1) and have produced at best, modest results. Scientifically the race is still on to find the 'best' type and source of cell to reconstitute the myocardium and improve function following myocardial damage. We are developing strategies that are able to specifically activate the resident CSC pool by using growth factors/cytokines, without the need for cell transplantation. We show that the growth factor IGF-1 enhances cell replication and attenuates CSC and cardiomyocyte senescence delaying the appearance of a cardiomyopathic old heart. Furthermore, using a clinically relevant experimental infarct animal model in hearts the size of human's, we show intracoronary injection of the growth factors IGF-1 and HGF after myocardial infarction in pigs has a protective effect on myocardial tissue organization and structure and produces significant CSC activation and ensuing regeneration. These results provide the proof-of-concept needed to justify further experimental development and refinement of this approach, which could ultimately lead to an effective, simple, clinically applicable and widely available protocol of myocardial regeneration, having significant impact on public health.

## ADULT STEM CELLS IN SKELETAL MUSCLE AGEING AND REGENERATION

HARRIDGE, S.

KING'S COLLEGE LONDON

The mechanisms underlying the age related loss of muscle mass (sarcopenia) are not fully understood. One view is that older muscles exhibit a deterioration in their ability to adequately maintain and repair themselves following damage. Mammalian skeletal muscle is a post-mitotic tissue relying on mechanisms of maintenance and repair. Satellite cells are the muscle stem cells which provide the source of muscle precursor cells for this purpose. They are activated from their quiescent state in the niche between the basal lamina and sarcolemma (where they express the marker Pax7) by exercise or damage. Once activated these cells, often referred to as "myoblasts" when they fall outside their anatomical location, can proliferate, fuse and differentiate (expressing myogenic differentiation markers such as myogenin and ultimately myosin heavy chain) and form new contractile muscle proteins and in culture fibre-like structures (myotubes). Evidence for an age-related impairment to repair following damage has come primarily from studies on rodents where some studies have shown older muscles exhibit a poorer recovery in terms of function (force) and / or markers of regeneration. Two main possibilities exist for such impairment in regenerative potential. Either the satellite cells themselves are intrinsically impaired by the ageing process, or there are factors in the aged milieu which negatively influence their behaviour. Data from early graft experiments on rodents, or more recently from conjoined circulation models, suggest that it is the age of the host and not the age of the damaged or grafted muscle that is responsible for this impairment. This points to factors in the local environment which are responsible for impaired regeneration. Impaired Notch signaling and increased TGF-beta expression in the satellite cell niche (Conboy et al. 2005) have been implicated in this process. However, there are also data which suggest less of a problem in this regard. For example, recent graft experiments on mice show that aside from a short delay there is an excellent myogenic stem cell response from older mouse muscles (Shavlakadze et al. 2010). Furthermore, whilst it is not possible to replicate the severity of the damage models used in rodents on human beings, that fact that the muscles of even very elderly people are able to adapt to strength training (increase muscle size and strength) and increase satellite cell number suggests that satellite cell function / the local environment is not limiting. Likewise, our experiments where primary human myoblasts are

cultured in sera from either young or elderly people, show no age-related impairment to proliferation or differentiation (George et al. 2010). In addition, whilst myoblasts obtained from both older and younger individuals show heterogeneity in their behaviour, there appear to be no obvious differences due to age. References Conboy I. et al. ## Invited symposia

### IS-SH01 Managing Talent in Professional Sport

#### MANAGING TALENT

RICHARDSON, D., NESTI, M., LITTLEWOOD, M., BENSTEAD, L.

LIVERPOOL JOHN MOORES UNIVERSITY

The aim of the presentation is to explore the notion of managing the development of talent within and through top-level professional football. Issues associated with player identity (i.e., through youth and professional environments), associated personal meaning that emerges from the 'real' and 'lived' experiences of talented players will be addressed. Furthermore the presentation includes more recent issues associated with the management of the migratory transition of young players. The presentation explores organisational structure and culture with respect to the strategic and operational working mechanisms that impact player development and progression. The symposium encourages participants to reflect on their own practice and/or experiences of managing young talent. Furthermore, the presentation will seek to provide examples of practices from across Europe in the strategic and/or operational approaches that may better facilitate the successful progression of talented players.

#### TOP FOOTBALL PLAYERS PERFORMANCE: THE IMPORTANCE OF RIGHT MANAGEMENT

DI SALVO, V.

ASPIRE/UNIVERSITY OF ROME

"Top football players performance: the importance of right management" V. Di Salvo <sup>1,2</sup> 1 Department of Health Science, University of Rome "Foro Italico", Rome, Italy. 2 Director of Performance Qatar Football Association, Qatar. There is a consensus in sport science that the most effective training is that which most closely replicate competitive performance condition. The growing interest for match analysis helped the understanding of physiological load imposed to football players (Di Salvo 2009, Rampinini 2009). The success of football performance is based on the functional adaptation between physical-psychological and the technical-tactical development. This optimal combination in the pursuit of a competitive advantage needs to start in the early stages of the elite football player's career and continue during the peak and post-peak years of the professional phase. In this context, fundamental will be the introduction of new philosophy based on the right management of the different areas in which sport science aspects, supported by new technologies, are combined with the specific football needs. The new tools and methodology have to be seen as additional help to be integrated with the actual know-how. Following the criteria of integration of new technologies, a strategic priority is the development of a training and performance centre with the goal of developing new approaches in the training methodologies area. This advance will produce a modern concept in the control of training with individualized programmes that will develop the performance and the longevity career of all athletes. The new philosophy is based on the interconnectivity of different areas and the integration of the results produced by them. The performance centre should be designed around different operating labs that through cross-platform activity and interchangeable data analysis optimize performance in the field by committing to the following: -Submission of functional evaluation monitoring the physiological characteristics of each athlete. -Development of individual training programmes. -Monitoring of training sessions and the evaluation of match analysis. -Conduct scientific research and apply to on-field practical application for improving the training methodologies. Objective data collected by the different labs should be combined from specific software and analyzed in an integrated way taking into consideration the correlation between the different parameters evaluated. Individual training programs must be designed with an overview on the different areas and considering and other important parameters as playing position, age, career level, physiological profile, games load (minutes played). References 1. Di Salvo, V., Gregson, W., Atkinson, G., Tordoff, P. & Drust, B. (2009) *J of Sports Medicine*, 30, 205-212. 2. #### YOUTH DEVELOPMENT: BEST PRACTICE IN EUROPEAN PROFESSIONAL FOOTBALL

SULLEY, C.

LEEDS UNITED FOOTBALL CLUB

Talent is regarded by many as the highest valued piece in the equation to deliver success. The talent pool in professional football that ultimately reaches its potential is small and very difficult to predict at the outset. The costs of identifying and developing talent are increasing as the implications of the FIFA rules on home grown quotas begin to take hold. Therefore, the search for, and development of, the best football talent in Europe is going to become more and more competitive. The average player cost spent in 2010 by the teams reaching the quarter finals of the Champions League was £16.2m up from £11.1m in 2009. This presentation is based on the findings of a 10 month research project that included over 10 field visits to some of Europe's best known professional football club Academy's and national associations for developing elite professional footballers. The presentation covers aspects of best practice in areas including; governance, investment, talent ID, coaching and development. Governance: Football governance is increasingly becoming the focus of the government, the public and football's governing bodies. FIFA's 'Financial fair play' rule is set to have an impact on how much clubs can spend but at the same time allow them freedom to spend any amount on youth development. Investment: Average Academy budget as a % of gross turnover was 7-15% in Europe. Barcelona, the top producer of elite young players was the highest total amount at 16m. The Premier League 20 clubs currently spend less than £40m per season in total on their Academy's, with the average gross turnover ranging between £40-80m. Talent ID: 'Think local act global'. Most clubs want to develop local talent to keep a local identity but accept that talent from foreign parts brings added value in different areas of the game. Linking into the local community at different levels is a key feature of best practice. Coaching and Development: 'Winning is more than just the score'. The key focus for top producing clubs is development over winning at all costs. This is to say that elite performers are encouraged to be task orientated, persistent and invest time and effort in themselves to achieve their potential. The facilitation of more practice time by catering for the education and welfare

needs of elite performers has long been accepted in countries that have consistently produced high performing professional footballers. Conclusion The presentation concludes with the view that clubs are required to aspire to these aspects of best practice in order to consistently produce high performance footballers.

### Plenary sessions

#### PS-PL04 NEW HORIZONS: In the Integration of Science and Football (Dedicated to Prof. Tom Reilly)

##### IMPORTANCE OF INTENSE TRAINING IN FOOTBALL

BANGSBO, J.

UNIVERSITY OF COPENHAGEN

The physical demands of a football player are high with elements of maximal force development, such as jumping, tackling and jumping, and high speed running. In addition, it has been observed that fatigue does occur both temporally and towards the end of a game. Therefore, it is important to prepare the players by doing aerobic and anaerobic training, which should preferably be performed in drills to ensure that the muscles used in football are trained and are obtaining the adaptations. In addition, such training does also develop the players' technical and tactical abilities. The aerobic training can be evaluated by measuring heart rate, e.g. heart rate during aerobic high intensity should be at the least 80% of maximum heart rate and on average around 90% at the end of each interval. Anaerobic training can be conducted as speed endurance production training, where the players are performing almost maximally for 10-30 s followed by long recovery period, and speed endurance maintenance training with intense exercise periods lasting 20-60 s separated by relative short recovery periods (1-2 times the exercise periods). Additional aerobic and anaerobic training during the season have been shown to improve performance level even for elite players. Thus, an additional 30-min aerobic high intensity training session a week for 12 weeks elevated the Yo-Yo intermittent recovery test performance (level 2; Bangsbo et al., 2008) by 18% (Jensen et al., 2009). Furthermore, in a recent study the effects of a 2-wk intensified training period were examined in trained soccer players (Thomassen et al., 2010). After the last match of the season seven elite soccer players in a 2-wk period perform 10 training sessions mainly consisting of aerobic high intensity training (8 x 2 min) and speed endurance training (10-12 x 30-s sprints). After the 2 weeks performance in ten repeated 20-m sprints was enhanced ( $33.44 \pm 1.17$  vs.  $32.81 \pm 1.01$  s;  $P < 0.05$ ; Fig. 2). In addition, the protein expression of the Na<sup>+</sup>/K<sup>+</sup> pump  $\alpha 2$  isoform was 15% higher ( $P < 0.05$ ) after the intervention period, whereas no changes were observed in  $\alpha 1$  and  $\beta 1$  isoform expression. Furthermore, running economy was improved ( $P < 0.05$ ), and the amount of pyruvate dehydrogenase was higher (17%;  $P < 0.05$ ). Apparently, intensified training of already well-trained soccer players can cause significant muscular adaptations and improve performance. References Bangsbo J. et al (2008). ##### THE TWO CULTURES OF FOOTBALL RESEARCH: EXPLORING THE POSSIBILITIES OF GREATER INTERDISCIPLINARITY

GIULIANOTTI, R.

DURHAM UNIVERSITY

This paper discusses the interconnections and synergies between researchers in the natural and social sciences with respect to research into football. Hitherto, collaborative research has been rather limited. I examine some of the main institutional and political constraints that have militated against collaborative work in the past. In social science, the lack of full engagement is notable, given shifts into new research and cross-disciplinary territories since the late 1980s, the rise of science and technologies studies (STS), and collaborative work in other fields across the 'two cultures'. I explore the broader professional context in which research might develop, for example with regard to common research settings, funding issues, and external performance pressures (e.g. the REF). I set out some of the possible research problems and issues which may be pursued collaboratively.

#### PP-SH17 Physical Activity & Health in Special Populations

##### THE RELATIONSHIP BETWEEN PHYSICAL ACTIVITY AND ARTERIAL STIFFNESS IN PUBERTY

MATSUMOTO, N.1, YOSHIOKA, A.2, TAKAHARA, T.3, NOSE, Y.3, TAKAGI, Y.3, SAITO, T.3, ARAKANE, K.3, YAMAGUCHI, H.4, IEMITSU, M.5, TAKAHASHI, K.6, MIYACHI, M.7, ONODERA, S.8

1)SHUJITSU JUNIOR COLLEGE. 2)KAGAWA UNIV. 3)GRADUATE SCHOOL, KUMMW. 4)KIBI INTERNATIONAL UNIV. 5)RITSUMEIKAN UNIV. 6)TAU. 7)NATIONAL INSTITUTE OF HEALTH AND NUTRITION. 8)KUMMW.

PURPOSE: The systemic arterial stiffness increases with aging. In addition, the high level of systemic arterial stiffness is an independent risk factor of cardiovascular disease. The systemic arterial stiffness is measured by the pulse wave velocity between brachial and ankle arteries (baPWV). Several studies reported that the increase in baPWV was restrained by habitual aerobic exercise in adults. However,

there are a few reports to show the systemic arterial stiffness in puberty. The purpose of this study were to measure blood pressure and baPWV in Japanese adolescents. In addition, we examined the relationship between physical activity and arterial stiffness in puberty. METHODS: four hundred eighty-one healthy Japanese adolescents participated in this study (290 boys and 191 girls, mean age: 13.5±1.0 years). We measured their height, body weight, baPWV and blood pressure. And we examined a sport habit and an outdoor play habit from questionnaire survey. Subjects were divided into two groups from sport habit; sport group (n=395) and non-sport group (n=104). In addition, we divided subjects into four group as physical activity by sport habit and outdoor play habit: Group1 had sport habit and outdoor play habit. Group2 had only sport habit. Group 3 had only outdoor play habit. Group4 had neither habit. We compared each baPWV and physical characteristics. RESULTS: The %body fat and baPWV of sport group was significantly lower than the non-sport group. The time of sport activity minute of one week in exercise group was 521.1±341.6 minutes. No significant correlation was between baPWV and time of sport activity of one week. The baPWV of Group1 was lowest (Group1: 937±133cm/s, Group2: 986±145, Group3: 1016±121, Group4: 1009±129). DISCUSSION: Results of this study suggest the systemic arterial stiffness of adolescents is restrained by physical activity. These results agree with the result of adult. It could be considered that the physical activity affects the arterial stiffness of the adolescents low. ## INTERACTION OF PHYSICAL MATURITY, BIRTH DATE, AND PHYSICAL FITNESS IN 10–11 YEARS OLD SCHOOLCHILDREN

WATANABE, M., YUGE, M.

COLLEGE OF EDUCATION

**Introduction** Children who mature earlier have larger bodies and superior muscle strength, which affect their selection as sports players. In fact, elite young players in many sports show early maturation (Malina et al. 2004). Their birth date affects their physical fitness and selection as players (Cobley et al. 2009). Because physical maturity and birth date have been researched separately, those factors' interaction (early maturity and later birth) with physical fitness remains unclear. This study is intended to assess the interaction of physical maturity, birth date, and physical fitness. **Methods** Subjects were 10–11 years old (fifth grade) public elementary school students: 396 boys and 371 girls. Their height, weight, hand grip, 50 m run, 20 m shuttle run, and softball throwing data were examined. Three four-month birth date groups were made (three of boys, three of girls). Physical maturity was assessed by height maturity (observed height / predicted adult height). Then students were separated to create three groups (three male, three female) of equal number. All events were compared for Early birth date - Early maturity (EE), Early birth date - Late maturity (EL), Late birth date - Early maturity (LE) and Late birth date - Late maturity (LL) groups using ANOVA. Here, early and late birth dates refer to their relation to the academic year. Results Early maturity groups (both sexes) showed large values for height, weight, and BMI. Hand grip data (both sexes) were significantly different between EE and LL. The 50 m run data for EE and LL in girls were significantly different. Results of the 20 m shuttle run for EL and EE in girls were significantly different. Softball throw data showed no significant difference between sexes. Most physical fitness events showed no significant difference among boys. **Discussion** Physical maturity affects body size and muscle strength more than the birth date does. The EE girls showed high performance for the 50 m run (explosive strength). This result suggests the influences of body size, muscle strength and maturation. In contrast, the later maturing girls showed superior results in the 20 m shuttle run (endurance ability). The lack of difference in softball throw results might be related to their high throwing skill. Although young athletes are affected by physical maturity and birth date, the influence is small for 10–11 years old school children. **References** Cobley S, Baker J, Wattie N, McKenna J. (2009). ## ASSESSMENT OF AEROBIC CAPACITY AND MUSCLE FUNCTION IN HIGH SCHOOL MALE STUDENTS

MANCHEV, A., PENCHEVA, N., STOILOV, A., KOTCEV, CH.

SOUTH-WEST UNIVERSITY

**ASSESSMENT OF AEROBIC CAPACITY AND MUSCLE FUNCTION IN HIGH SCHOOL MALE STUDENTS** Manchev, A.1, Pencheva, N.1, Stoilov, A.2, Kotcev, Ch.1 1:Department of Sports and Kinesitherapy and 2:Department of Physics of SOUTH-WEST UNIVERSITY (Blagoevgrad, Bulgaria) **Introduction** The role of the physical education teacher is to prepare proper programs of the students and to develop their fitness level in aerobic capacity and muscle strength. So, the aim of our study was: - to test the aerobic capacity and isokinetic knee and ankle muscle strength of male students; and - to assess the correlation between the isokinetic muscle strength and aerobic aptitude of the students. **Methods** Twenty male, high school students (age: 22.5±2.3 years; height: 178.4±1.3 cm; weight: 79.1±3.0 kg) performed treadmill test (Tzvetkov et al., 2008) at an initial speed of 6 km/h, an increase by 1.2 km/h every 90 s until exhaustion. To measure student's maximal ankle (plantar/dorsal flexion: speed - 30, 60, 120 °/s) or knee (flexion/extension: speed - 60, 180, 300 °/s) muscle strength, an isokinetic dynamometer (Biodex System 4 Pro) was used. Body composition was assessed by electrical bioimpedance. Results The mean values ± SD for the peak responses of VO<sub>2</sub> (ml/min/kg), VE (l/min), HR (bpm) and speed (km/h) were: 48±5, 115±25, 190±8 and 11.2±0.9, respectively. The knee extensor/flexor peak torque (mean±SEM) at 60, 180 and 300 °/s was 230±12/117±6, 150±8/87±5 and 104±6/67±4 Nm respectively. The maximal isokinetic plantar/dorsal flexion torques at 30, 60 and 120 °/s were 118±9/45±4, 101±8/34±2 and 75±5/23±2 Nm respectively. A decrease (p<0.05) of the knee flexion/extension ratios, was established. The individual muscle strength for knee extensors, knee flexors and ankle plantar flexors was significantly (p<0.05) related to the fat free mass (r=0.80). However, neither peak VO<sub>2</sub>, nor other parameters of aerobic capacity were related to the muscle strength. **Discussion** Isokinetic muscle strength and maximal aerobic capacity are independent of each other in untrained male students. However, the values for isokinetic knee and ankle muscle strength, which are in agreement with those of other researchers (Dvir, 1995; Schiltz et al., 2009), are accompanied with average aerobic capacity and low pulmonary ventilation. So, the relevant physical education programs have to be recommended in order to increase the cardiopulmonary endurance and aerobic power of the students, although the majority of them prefers isometric training. Because of the muscle imbalance between knee flexors/extensors, special exercise, to increase the strength of hamstring is also appropriate. **References** Dvir Z. (1995) Edinburgh, United Kingdom: Churchill Livingstone. Schiltz M, Lehance C, Maquet D, Bury T, Crielaard JM, Croisier JL. (2009) J Athl Train 44(1), 39-47. ## CASE STUDY OF THE EFFECTS OF DAILY PHYSICAL ACTIVITY ON THE ENDURANCE ABILITY IN A BOY WITH DOWN'S SYNDROME

OHASHI, C., KANEKO, R., MATSUI, S., HIBI, N.

TOYAMA NATIONAL COLLEGE OF TECHNOLOGY

**Introduction** Much research points out that the physical fitness levels of special needs children are much lower than that of healthy children. The main factor is thought to be a result of a low quantity of daily physical activity among special needs children. Moreover, in children with Down's syndrome, fitness levels are much lower and the incidence of obesity is much higher. The purpose of this study is to investigate the effects of daily physical activity on the endurance ability in a boy with Down's syndrome. **Results** The subject was 11 years old and was a student at a school for special needs education in Japan. We examined the subject's obesity index using the Rohrer-index and Skinfold thickness method, as a result he was termed mildly obese (Rohrer-index: 161.4, body fat: 24.8%). The quantity of his daily physical activity and intensity (light, moderate and vigorous) was estimated by a pedometer (Lifecorder) over two periods: during the school term and the summer vacation. There were significant differences between the school term period and the summer vacation period in number of steps: steps/day ( $9347 \pm 1561$  vs  $7086 \pm 2517$ ,  $p < 0.001$ ), light activity: min/day ( $70.7 \pm 10.3$  vs  $52.6 \pm 13.0$ ,  $p < 0.001$ ) and vigorous activity: min/day ( $6.4 \pm 2.9$  vs  $2.7 \pm 1.6$ ,  $p < 0.001$ ). There was no significant difference in moderate activity. We conducted walking tests before and after the summer vacation to examine the regression line between walking speeds(y) and heart rate(x), which we used as the index of endurance ability. The regression line changed from  $\text{prely} = 1.432x - 108.2$ ,  $r^2 = 0.97$  to  $\text{postly} = 0.415x + 1.42$ ,  $r^2 = 0.99$ , for example the walking speeds at HR 120 beats/min changed from 63.6m/min to 51.2m/min. **Findings** The subject's walking speeds at HR 120 beats/min decreased from 63.6m/min to 51.2m/min after summer vacation. This shows the possibility of a decline in endurance ability over that period of time. We suggest that the decrease in the quantity of daily physical activity during summer vacation influenced the decline in endurance ability. Therefore children with Down's syndrome should maintain a certain level of physical activities as much as they can in their daily lives, and improve their fitness for prevention of other lifestyle-related diseases in the future. We must also support them to become, and remain, healthy in cooperation with teachers, family and their community. We're developing a Smart Phone application that will act as a physical activity support tool for special needs children. We plan to work with teachers of special needs education and will try to support special needs children's physical activity using Smart Phone with particular attention on long-term holidays.

## PHYSICAL ACTIVITY AND BREAST CANCER PREVENTION

CAZZOLI, S., MANO, M.P.

MIUR MINISTER INSTRUCTION UNIVERSITY RESEARCH UST TURIN

**PHYSICAL ACTIVITY AND PREVENTION BREAST CANCER** Cazzoli S., 1, Mano MD 2, 1: MIUR Minister Instruction University Research (Turin, Italy) 2: Department of Biomedical Sciences and Human Oncology, CPO Piedmont, University Hospital San Giovanni Battista Turin (Italy) **Introduction** Physical inactivity has been identified as the fourth leading risk factor for global mortality (6% of deaths globally). The Physical Activity for Health are relevant for the following health outcomes as cancer (breast and colon cancer); functional health and prevention of falls; depression and cancer (breast and colon cancer). (WHO, 2010) La maggior parte degli studi indicano una riduzione del rischio tra il 20% l'80% del CA mammario nelle donne che praticano l'Attività Fisica The literature show that physical activity to prevent from 20% to 80% the development of recurrences in breast cancer (BC) (Fraser GE, Shavlik D, 1997- Dallal CM, Sullivan-Halley J, RossRk, Wang Y, Deapen D, Horn-Ross PL, Reynolds P. Stram Do, Clarke CA, 2007) The aims of the study is education programme for change the life style in woman after breast cancer treatment and prevention of secondary . recurrence in Piedmot (Italy Methods The educational protocol was based nutrition and PA lecture, cooking and gymnastic session. (low impact aerobic gymnastic, yoga , Tai Chi, dance, martial arts, Nordic Walking Results The sample was 58 womens (Breast cancer operated by less than 5 years) and after 1 years of PA educational training the style of life changed: no activity (before 62% after 46,5%): Tipe of activity: no formal (before and after 13,8%) formal (before 24,1% after 34,5%); PA in different age and intensity aged 0-3years; 6-11y; 11-14y; 14-19y; 19-26; 26-35y, Over. Discussion The active life style was determined by personal and cultural factors. They can be supported by: Information Training Support structural and tutorial short-and long-term intervention References WHO, Global recommendations on physical activity for. (2010). ## RISK FACTORS OF BACK PAIN IN PRIMARY SCHOOL CHILDREN

FRATTINI, G., ADDOLORATO, S., CASOLO, F., VAGO, P., GALVANI, C.

CATHOLIC UNIVERSITY OF MILAN, ITALY

**INTRODUCTION** The aim of this study was to determine the impact of back pain in primary school children and identify any predisposing risk factors. We aimed to address two fundamental questions: 1) What percentage of primary school students suffer for back pain? 2) What are the main risk factors of back pain in this population? **METHODS** A group of 804 children aged from 5 to 11 years was tested. The sampling involved both sexes and was based on random sampling. Data were collected through a survey sent to the pupil's parents and involved a questionnaire, SDQ-Ita (R. Goodman, 1997) concerning anthropometric data, ability/ difficulties (psychological /psychosocial) and lifestyle. Specific questions on pain and back diseases were asked only to those parents whose children had already encountered this problem. Data are expressed as Average and Standard Deviation, where appropriate. Graph data are expressed as a percentage. Descriptive Statistics was performed with the Microsoft Office Excel 2003 (Professional Edition). Inferential Statistics was performed with the statistical program Statview 5.0. implementing the Binary Logistic Multiple Regression, also calculating the Odds Ratio and Confidence Interval. **RESULTS** Risk factors considered were: female sex, the index of weekly lack of movement and family history of back pain. The incidence of back pain in the sample analyzed was 18%. The incidence of back problems steadily increased from the Year 1 (7.4%) to Year 5 (27.5%) of primary school. The difference between the sexes was 5.3%, (20.2% in girls versus 14.9% in males). Pathological familiarity with at least one family member presenting back pain, was found in 48% of sample examined. The data show for Years 1, 2 and 3 that, as the average time spent in sedentary activities increases from 24% in Year 1 to 40% in Year 3, reaching up to 50 hours per week in Years 4 and 5, the probability of back pain/disorders increases to 57% and 58%. **DISCUSSION** In correspondence with the literature, we

found that there was no correlation between back pain and sleeping position during the night and between back diseases and psychological/psychosocial factors identified by the questionnaire SDQ-Ita. Too much activity or the practice of a sport on a regular basis for more than twice a week does not seem to increase risk of back pain. The present findings warrant the implementation of programmes aimed at reducing physical inactivity among school children. The effectiveness of such programmes requires not only the involvement of coaches and educators but also family support. The best prevention of back pain and spine disorders should in fact start at an early age.

### PHYSICAL ACTIVITY BEHAVIOUR OF UK WOMEN WITH BREAST CANCER

STEVINSON, C., LYDON, A., AMIR, Z.

LOUGHBOROUGH UNIVERSITY

**PHYSICAL ACTIVITY BEHAVIOUR OF UK WOMEN WITH BREAST CANCER** Clare Stevinson [1], Anne Lydon [2], Ziv Amir [2] 1. School of Sport, Exercise and Health Sciences, Loughborough University, UK 2. School of Nursing, Midwifery and Social Work, University of Manchester, UK Physical activity is recommended following breast cancer treatment based on evidence of positive effects on quality of life, weight control, and survival. Nonetheless, data from North America suggest that few breast cancer survivors meet the minimum guidelines ( $\geq 30$  minutes of moderate/vigorous intensity activity on  $\geq 5$  days per week). **PURPOSE** To determine the prevalence and predictors of physical activity among women with breast cancer in the United Kingdom. **METHOD** As part of a national survey of cancer support group participation, questionnaires including items on physical activity and demographic/medical information were completed by 365 women with breast cancer. **RESULTS** The mean number of minutes of moderate/vigorous intensity physical activity reported per week was 70.7 (standard deviation = 119.5). Overall, only 63 (17.3%) participants were meeting minimum guidelines. The likelihood of meeting physical activity guidelines was higher in participants who were younger than 60 years [relative risk (RR) = 1.93; 95% confidence interval (CI): 1.23 to 3.03], working full/part time [RR = 2.10; 95% CI: 1.34 to 3.27], and in good health [RR = 2.31; 95% CI: 1.28 to 4.18]. Medical variables (disease stage, disease status and time since diagnosis) were not associated with physical activity behaviour. Among those not currently meeting guidelines, 64.4% felt that they should be more physically active. **CONCLUSION** Physical activity levels are low among women with breast cancer in the United Kingdom. However, the majority of insufficiently active participants showed awareness of the need to increase their activity, and may be receptive to interventions for promoting physical activity.

### THE RELEVANCE OF THE BIOMARKER S100B IN THE CONTEXT OF PHYSICAL ACTIVITY – AN OVERVIEW

SCHULTE, S., SPERLICH, B., SCHIFFER, T.

GERMAN SPORTS UNIVERSITY COLOGNE

**Introduction** S100B is a biomarker for various central nervous system injuries predicting a bad outcome with increased concentrations. It has received growing attention in scientific publications over the last decade. However, there is still no consensus regarding the physiological mechanisms alternating the concentration of S100B (S100B) such as physical activity. The aim of this study is to provide an overview of all publications concerning S100B as a diagnostic tool in the context of physical activity. **Methods** A) Content analysis of a full sample survey of abstracts enlisted in the database PubMed from the last 15 years (1995-2009). • Questionnaire: 4 sections with 22 variables (CR>0.9) • Software: EndNote X3, SPSS Statistics 19 B) In-depth content analysis of selected articles resulting from A) **Results** A) 1747 abstracts are assembled thereof 17 abstracts with S100B used as a diagnostic tool in the context of physical activity. These 17 abstracts are considered in the results: - Published in: 14 journals (2003-2009) - Address corresp. author: Europe (15) (Sweden, Germany, Greece, UK, Italy) and in the United States (North (2), South (1)) - Name of the protein: S100B (5), S-100B (7), S100beta (4), S-100beta (1) - Method of measurement: Immuno Assay (1), biochip array technique (1), not detectable (15) - Unit of measurement: mg\*L-1 (6), ng\*mL-1 (2), not detectable (9) - Carrier: serum (11), saliva (1), peripheral tissue (1), not detectable (4) - Measured values: 0.05-0.28 mg\*L-1 - test subjects: human (16), rat (1) - sex of the test subjects: male (7), female (1), not detectable (10) - physical activities: apnoe diving (2), boxing (2), exercise in heat (3), heading/soccer (8), physical exercise (1), running long/short distance (3/1), swimming race (1), walking (1), not detectable (1) B) Further results will follow **Discussion** Relevant information is often not detectable on the level of abstracts. Further results will follow by an in-depth content analysis of articles based on the choice of A). The design and the results described in the selected abstracts differ. Hence, it is difficult to gain a consistent knowledge regarding the impact of physical activity on [S100B]. Serum S100B values in healthy individuals range from 0.02 to 0.15  $\mu\text{g}\cdot\text{L}^{-1}$ . Results of our investigation show increased [S100B] in healthy persons after physical activity that exceeding this range and discuss it as a possible health risk. The dualistic view that values S100B alterations by physical activity as 'bad' or 'good' distorts the comprehension of the role of this protein in physiological conditions and in cerebral disorders. **References** 1 Dassan P, et al. (2009). Cerebrovasc Dis. (27), 3, 295-302. 2 Ben Abdesselam O, et al. (2003). Clin Chem, (49), 5, 836-7.

### FATTER - BUT MORE ACTIVE? LEVELS OF LEISURE TIME PHYSICAL ACTIVITY IN A NORWEGIAN POPULATION 1984-2008. THE NORD-TRØNDELAGE HEALTH STUDY

MOHOLDT, T., ASPENES, S., WISLØFF, U.

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

**Background** As all western countries experience an increase in the prevalence of overweight and obesity, one could expect a decrease in leisure-time physical activity (LTPA) level. The aim of this study was to describe changes in LTPA in a general Norwegian population from 1984-86 to 2007-08, and to analyze these changes in relation to changes in body mass index (BMI), resting heart rate, and blood pressure in the same time period. **Methods** We used data from the Nord-Trøndelag health study (HUNT, part 1-3), with data on self-reported LTPA amount and intensity from 61 547 subjects in HUNT1 (1984-1986) and from 42 753 subjects in HUNT3 (2007-2008). We compared LTPA in subgroups of participants, according to gender, age, and BMI, and considered LTPA-data in light of population changes in BMI, blood pressure and resting heart rate. **Results** The main changes in physical activity from 1984-1986 to 2006-2008 include a decline in the proportion of the population reporting < once weekly LTPA (from 41.0% in HUNT1 to 21.8% in HUNT3), and an increase in the proportion reporting  $\geq$  twice weekly LTPA (from 35.0% in HUNT1 to 56.7% in HUNT3). In this time period, BMI increased from 25.2 (SD 3.9) to 27.1 (SD 4.4) Resting heart rate decreased from 74.7 (SD 12.5) to 70.4 (SD 11.7), and systolic and diastolic blood pressure decreased from 138.5 (SD 23.5) to 130.8 (SD 18.5) and from 84.6 (SD 11.6) to 73.5 (SD 11.2), respectively. We saw similar increases in frequency, duration and intensity of LTPA across genders, age groups and BMI subgroups from HUNT1 to HUNT3. **Conclusion** Although self-reported LTPA increased in a Norwegian population from 1984-1986 to 2007-2008, BMI increased in the same time period. This apparent paradoxical trend could possibly be explained through a parallel increase in sedentary time or by changes in diet.

## THE PHYSICAL ACTIVITY LEVELS AND PLAY BEHAVIOURS OF YOUTH WITHIN A SPECIAL SCHOOLS SETTING: AN OBSERVATIONAL STUDY

BODDY, L.M., BINGHAM, D., RIDGERS, N.D., STRATTON, G.

LIVERPOOL JOHN MOORES UNIVERSITY

THE PHYSICAL ACTIVITY LEVELS AND PLAY BEHAVIOURS OF YOUTH WITHIN A SPECIAL SCHOOLS SETTING: AN OBSERVATIONAL STUDY Boddy, LM,1-3, Bingham, D,2, Ridgers, ND,4, Stratton, G.,2,3 1: ECL, LJMU, UK, 2: RISES, LJMU, UK, 3: The REACH Group, UK, 4: Centre for Physical Activity and Nutrition Research, Deakin University, Australia Introduction Limited research has been conducted within Europe investigating the habitual physical activity (PA) levels and recess PA behaviours of children with Special Needs (SN). International evidence suggests that children and adolescents with disabilities and/or SN are less active than their non-SN peers (Pan, 2008). The aims of this study were to estimate the habitual PA levels and recess play behaviours of children that attended special schools, and to investigate whether PA levels and play behaviours differ by classification of SN. Methods Twenty-five children/adolescents (aged 8-16 years) from 3 special schools in the North West of England participated in this study. PA was monitored over a 7-day period using accelerometry. Recess behaviours were observed for 10 minutes during one recess period using the System for Observing Children's Activity and Relationships during Play (SOCARP). Participants' individual special need(s) were reported by parents and participants were categorised into one of three groups, namely: autism (AUS), behavioural and emotional needs (BEN) and any other SN (OTH). Results Participants failed to meet the recommended daily amount of 60 minutes of moderate to vigorous physical activity (MVPA) per day (group mean 46.88 minutes, SD = 9.10). SN group comparisons found that participants with BEN (65.55 min, SD = 20.50) were significantly more active than participants with AUS (43.40 min, SD = 27.50) and OTH (32.35 min, SD = 17.84) ( $p \leq 0.05$ ). Using SOCARP, group differences in recess MVPA were observed between the groups, (BEN group: 65.54%, AUS: 43.40% and OTH: 37.92%) however these differences were not statistically significant. Participants with AUS spent more time playing alone and less time playing in groups in comparison to the BEN and OTH groups ( $p \leq 0.05$ ). Furthermore, interactions between all participants and their peers were low, with a group mean of 3 interactions per 10 minute observational period. Discussion Findings of the study suggest that children and adolescents with SN did not meet the national PA guidelines of 60 minutes MVPA per day. Furthermore, children with BEN were more habitually active than those with AUS and OTH. Mean data also suggest that children with BEN took part in more MVPA during recess. In addition, AUS participants spent less time playing in groups than OTH and BEN, suggesting that recess behaviours differ by SN. Larger studies are required to gain a better understanding of recess behaviours and the habitual physical activity levels within SN youth. References Pan, C.Y. (2008). Journal of Autism and Developmental Disorders, 38, 1292-1301.

## INFLUENCES OF PHYSICAL EXERCISES ON ALLEVIATING LOWER BACK PAIN AND PSYCHOLOGICAL CONDITIONS

NIGORIKAWA, T., ENDO, S., KATO, H., ISHIWATA, T., KANOU, H., HIRONO, M., OISHI, K., YASUKAWA, M.

RIKKYO UNIVERSITY, CHUO UNIVERSITY\*

Introduction Lower back pain (LBP) in Japanese peoples became a serious social problem. There are several previous researches that have indicated that certain types of exercise are effective for alleviating and preventing LBP. Among these researches, there have been some findings that suggest that the basic movements of the traditional Japanese sport of 'sumo wrestling' may be effective for alleviating LBP. However, there have been hardly any empirical studies conducted on this subject. On the other hand, several researches have pointed out that psychological factors may be involved in LBP. At the present time, however, these research results have not yet reached the level of being generally accepted, and it is hoped that further studies will be conducted. Accordingly, this study was conducted to demonstrate the effect of 'the sumo exercises' on alleviating LBP, and to clarify the relationship between LBP and psychological factors. Methods The subjects of the study consisted of 242 adults (77 men and 165 women). These subjects were interviewed to determine the presence or absence of LBP and subjected to four types of psychological tests. The psychological tests consisted of the Big Five personality test, Daily Hassles Scale, SRS 18 test and Purpose in Life Tests. Moreover, the subjects were divided into the following four groups and assigned tasks consisting of 'the sumo exercises', 'conventional lower back exercises', 'the Rikkyo University-type exercises' and 'no exercises' those performed for 10 months. A comparative study was then made of the preventive and ameliorative effects demonstrated by these exercises. Results Correlations with LBP were detected for all psychological parameters. These results showed that persons in a desirable psychological state having low levels of apprehension or anger had a lower degree of LBP. In addition, the effects of each type of exercise were also demonstrated. Discussion In the prevention and alleviation of LBP, an organic (anatomical) approach has conventionally been primarily employed that consists of strengthening supporting muscles of the spine, including abdominal muscles and muscles along the spine. The results of this study, however, supported former reports suggesting the correlation between LBP and psychological factors. It was suggested that a psychological approach should be adopted when attempting to alleviate LBP in the future. In addition, it was discussed that those exercises not only had the effect of strengthening muscle groups that supported the spine, but also refreshed the subjects performing the exercises.

#### WHAT'S THE DIFFERENCE BETWEEN NORWEGIAN AND DUTCH ELITE FOOTBALL PLAYERS

JAKOBSEN, A.

UNIVERSITY OF NORDLAND

Introduction The Norwegian top football centre have started a project they have called the "Worlds best". The aim for the project is to identify world-class competence in football and to find what's behind the success. The centre have made an analyse to separate "good to great", "built to last" and "how the mighty falls" nations. (Collins 2009) Holland was the "good to great" nation that was most similar to Norway. (Johansen 2010) The main aim of this study was to look for differences between Norwegian and Dutch players in age, age when they debuted at the top level, their club background and national background, if they have played for the youth national teams, if they have played on the second highest level before they entered the highest level, what time of the year they was born, their height and if the Dutch players had went trough one of the top level clubs academies. Method: The data is collected from the internet pages for the clubs. The population consists of 321 (mean age 25,92 years +/- 5) Norwegian players and 389 (mean age 24,73 years +/- 4,5) Dutch players

from 16 Norwegian and 18 Dutch clubs. Data were coded for further analysis in SPSS 15.0. Chi square analysis were undertaken to check for differences between the two countries. Significance level was set to  $p \leq 0.05$ . Results: 50 % of the Norwegian players were under 25 years old compared to Holland 63 %. 50 % of the Dutch players came from a club in the two highest divisions compared to Norway 33 %. In Holland 64 % of the players had their debut in the "Eres" division at the age of 19, compared to Norway where 45% had their debut at the age of 19. In Norway only 32 % of the players are foreigner and in Holland it is 45 %. 30 % of the Dutch players played on the second level before entering the highest, in Norway 40 % did the same. 70 % of both Norwegian and Dutch players are higher than 180 cm. There is no difference between the two populations when it comes to which time of the year they are born. About 33 % of the players are born in the second quartile which is higher than the other three. Only 12 % of the players in both countries had played on the national youth team. In Holland 47 % of the players had been through any of the academies. Discussion: There are some differences between Norway and Holland when it comes to age of the players, when they have their debut on the highest level; there are more foreigner players in Holland than in Norway and more of the Norwegian players had played on the second highest level before entering first level, but there is no significant difference in any of the items. There are no differences at all between the two countries in height of the players, which time of the year they are born and how many players which have played on the national youth teams. ## THE CORDIAL IDENTITY OF BRAZILIAN OLYMPIC FEMALE ATHLETES

RUBIO, K., NASCIMENTO, P.  
UNIVERSITY OF SÃO PAULO

**Introduction** Until the second half of the twentieth century, sports was seen as a male institution, whereas the female athletic experience was disregarded. Once excluded from stadiums and other sport places, as well as from the public life determined in that age, the female condition was limited to the dedication to home and family. In Brazil this situation repeats itself. Although the Brazilian women participation on Olympic Games started in Los Angeles 1932, the first medals, symbol of Olympic sportive efficiency, were conquered only in 1996. Although there is an official speech denying the prejudice towards the female sports practice, it is possible to observe throughout Brazilian History the forbiddance for girls of some sportive practice at school like soccer and judo, triggering a delay in performance comparing men in Olympic competition. **Objective** The objective of this paper is to present the trajectory of Brazilian female sports and to show social and cultural aspects that contributed for the actual stage. **Method** The method for this investigation was Oral History, more specifically Life Histories. 270 interviews with female athletes were made, who participated in Olympic Games since 1948 until 2008, medalists and non-medalists. The age from these athletes ranged from 22 to 83 years old. From their narratives specific elements were taken to debate the identity issue. **Discussion** The development of the Brazilian Female Athlete's identity in Brazil follows different paths than in the USA or in Europe. This situation is directly connected with the directions of the feminist movement in the broadest sense, nearing what Buarque de Holanda features as "cordiality". The sense of cordiality in Brazilian culture points to a way of solving disagreements and disputes in an affective way, avoiding the straight and objective conflict. The development of this attitude can be perceived in the non-observance of discrimination and prejudice by the female athletes themselves. From the 270 interviewed athletes, only 7 of them have attributed discrimination to the fact of being women, either receiving less prizes and sponsorship than men or being forbidden to take part in some competitive activity because clearly for the fact of being women. **Conclusion.** The non-recognition of gender discrimination by Brazilian Female Athletes indicates a characteristic of the feminist movement in Brazil: to look for a way of conciliation, more than confrontation. This appeasement of gender relations in sports brings results such as the difference in the prizes' payment, less participation in sponsorship's money and less social recognition for the effort that provided the conquest of this position.

## RESPONSIBILITY IN WILDWATER SPORTS

INGLES YUBA, E., MARTIN, A.  
INEFC

**Introduction** In the last years, the sports practice in natural areas has experienced an exponential growth, both in number of users and in diversity of the existing modalities. The shortage of legislation about it (Nasarre et al., 2001) causes the non-existence of standard criteria for the determination of the responsibility in all the incidents. Therefore, focusing our attention on the wildwater sports modalities - canyoning, canoeing, rafting and hydrospeed-, we present the analysis of the judgments of the accidents happened in Spain since the 80s. **Method** The method used is based on the analysis of content of the existing judicial judgments on Spain of accidents during the practice of wildwater sports: findings of fact, grounds of law and ruling of the judgment. **Results and discussion** In 5 of the 15 analyzed cases the accident ended with the death of the victim. Even so, it is surprising to realize that only one of them was taken to the criminal courts. In relation to the ruling of the judgment, only in the 13 % of the cases the demand sued by the victims or their family was totally considered. In more than the half of the cases (67 %), the demand was totally rejected and in a 20 % of the cases, it was partially considered. In only a 13 % of the cases considers the sued party (people or entities in charge of the activity) as the entire responsible of the accident. On the other hand, in a 33 % of the cases, the victim is defined as the responsible of his own injuries, by the consideration of the own assumption of risk (Ortí, 2001) and the principle of self-protection. In only a case it is considered the shared responsibility. It is necessary to emphasize that in almost the half of the analyzed judgments (47 %) it is determined that the responsibility cannot fall on any of the implied parties, because of the assumption of the implicit risk of the activity. The changeable conditions of the natural areas and the diversity of accidents that can take place, do not allow an establishment of a few criteria applicable to all the cases. Nonetheless, through the analysis of the existing judgments, we can observe trends in the jurisprudence on the accidents happened during the sports practice in the natural areas. **References** Nasarre, J.M.; Hidalgo, G.M.; Lucia, P. (2001). La vertiente jurídica del montañismo. Zaragoza: Prames. Ortí, A. (2001). La jurisprudencia sobre responsabilidad civil deportiva. Pamplona: Editorial Aranzadi.

## ROLES' DYNAMICS INSIDE SPORTS TEAMS: FACTUAL AND PERCEPTUAL ASPECTS

SIMION-DUMITRIU, D.  
NATIONAL SCHOOL OF POLITICAL SCIENCES AND PUBLIC ADMINISTRATION

**Introduction** The first step in analyzing the evolution of a team is to understand the dynamics of the group as a social unit. Focusing on the dynamics of roles inside the team, the main aim of this study is to analyze the relationship between the social dimension and the task dimension of the group. Moreover, these aspects of group dynamics are approached from two complementary perspectives that are

based on a re-contextualisation of the looking glass self model: the manner in which each athlete perceives that he is seen by his colleagues and the way he himself evaluates other members' positions inside the team. **Methods** The research design of this case study on a professional handball team from the Romanian Feminine Handball Championship is based on a mix-method approach that combines a sociometric analysis of group members' relationships, on both factual and perceptual level, with the observation method applied during training and competition contexts over a period of two competition seasons and in-depth interviews with the team's coach. **Results** The results revealed the fact that there is a contamination effect between the social evaluation of the members' positions inside the team and the task evaluation of their positions at the group level. Another key finding is that, if the difference between athletes' individual performance is not very significant - in terms of objective indicators of performance, the level of intra-group competition has a direct impact on how other group members' positions in the team are evaluated. **Discussion** The fact that the analysis of team's dynamics follows the group social evolution and is not limited to just a one-time frame is relevant for understanding the nature of interactions inside a sports team. Based on the comparison between the athletes' self perception and their actual position inside the team, one can therefore understand the possible directions of evolution regarding team's dynamics. Moreover, the study outlines the relationship between the actual positions that athletes have in the team and their perceptions of group dynamics, setting the objective dimension against the subjective dimension of roles' dynamics inside the team.

## SPORT CLUBS IN CATALONIA. CATALAN SPORTS OBSERVATORY

MARTIN, A., INGLES, E., JUNYENT, R.

*INEFC*

**Introduction** The Catalan sports system generates a large volume of information that is dispersed among organisations, communities, teams and individuals of the world of sport. In this sense, the main objective of the Catalan Observatory of Sport is to manage and structure all this knowledge and make it accessible to everyone. One of the working lines in order to build this knowledge is through research studies. Here, we present the study results on the situation of sport clubs in Catalonia (General Secretariat of Sports. Catalan Sports Council, 2010). Due to the lack of previous studies at the state level, a research study carried out in Germany was used as a model (Heinemann & Schubert, 1994). **Methods** The method used for this research was based on a questionnaire and its application has been through a standardized interview (demoscopic interview). The questionnaire consisted of a total of 52 questions of which only 2 were open and the rest were closed. The sample of 1,000 clubs was considered to be of a high representativeness as the results were applicable to 95% of the Catalan sport clubs with a margin of error of only  $\pm 3.0\%$ . **Results and discussion** In Catalonia there are 8,285 sport clubs. Half of them have no more than 100 individual members and only 5% exceed 1,000. More than one third (36%) of the clubs were founded after 1997. In relation to their members, 62.6% are men and 37.4% are women. This difference is even bigger in the presence of women (20.7%) on the boards, where only 11.9% hold the presidency. In the Catalan sport club 39% of the people involved in the daily running of the club are voluntary. This implies a valuation of more than 213 million euros annually. Catalonia has 69 sport federations and 91% of the Catalan sport clubs are members of one or more of them. The three federations with more clubs are Football (17.7%), Hunting (9.4%) and Basketball (5.8%). Although, the majority of the sport clubs (88%) were constituted with the purpose of competing, 71% of these offer complementary activities outside competition. **References** Heinemann, K., Schubert, M. Available: [http://articulos.revista-apunts.com/49/ca/049\\_010-019\\_cat.pdf](http://articulos.revista-apunts.com/49/ca/049_010-019_cat.pdf)

## CAREER TRANSITION OF ELITE ATHLETES IN HONG KONG

SUM, K.W., MOK, H.

*THE CHINESE UNIVERSITY OF HONG KONG*

**Introduction** According to the statistics of the Home Affairs Department of Hong Kong China, the number of athletes receiving training and support from the Hong Kong Sports Institute (HKSI) in elite and non-elite sports has grown from 545 in 2005 to 863 in 2009 (LegCo, 2010). Whether or not an elite athlete experiences his/her glorified moment in the sports arena, ultimately, retirement from a sports career is inevitable (Stier, 2007). There are approximately 30-40 elite athletes who retire every year. The retirement age ranges from 25 to 29 (LegCo, 2010). Therefore, the purpose of this study was to explore the process of career termination of retired elite athletes in Hong Kong. The research aimed at adding information to the literature of sports career transition in an Asian context. The results of the research would help athletes, coaches, and managers to understand the process, and how elite athletes cope with career transition. In addition, the intent was to provide insights for development of career assistance and support systems in Hong Kong. **Methods** A qualitative research design was adopted. Utilizing a purposive sampling method, 3 elite athletes in the fields of swimming, fencing and rowing, who had retired from training, participated in an in-depth semi-structured interview. Each of the athletes had participated in the East Asian Games (EAG) or the Asian Games (AG) and was medalists. One of them participated in the Summer Olympic Games (OG). Interview questions were modified, from guided questions created by Kadlicik and Flemr (2008), to suit the Asian context. The questions focused on the participants' experiences in the transition process from the athletic life to the post-sport life. Applying the principles of grounded theory (Strauss & Corbin, 1998), qualitative data generated from the interviews were analysed, coded and utilized. **Results** The results were developed from the following three dovetailing transition stages: a) the active athletic identity stage; b) the realization of termination stage; and c) the adjustment stage. The associations between each stage are variable according to an individual's response to the environment, and to the impact of interventions for coping with the termination experience. **Discussion** Although the three conceptualized stages of career transition are based on the retrospective data of three retired elite athletes, the findings were consistent with the previous findings of Stambulova et al. (2009) and Taylor & Ogilvie, (2001) which suggested that athletic career termination was not a single event but a transitional process. Career transition might not be a crisis or "social death," but could evolve as a result of appropriate interventions at different stages. This study also revealed that each transitional stage dovetailed with the other which means that the termination factors had started somewhere in the strong identity stage and were on-going through the process.

## PSYCHOSOCIAL INTERVENTION PROGRAMME USING BASKETBALL TO DEVELOP LIFE SKILLS IN YOUTH AT RISK OF DELINQUENCY \*

LAPOINTE, L.I., LABERGE, S.I., DUSSEAU, M.2

1: DEPARTMENT OF KINESIOLOGY, UNIVERSITY OF MONTREAL, 2: CSSS JEANNE-MANCE, MONTREAL, QUÉBEC, CANADA

**Introduction** Adolescents from underserved multiethnic milieus are at risk of school drop out and of getting involved in street gangs. The "Bien dans mes baskets" (BdmB) programme, implemented in 2001 in a high school of Montreal (Québec), uses basketball to reach adolescents at risk of delinquency. The main characteristic of BdmB is that the coaches are also social workers that intervene among adolescents through an extracurricular basketball programme. They focus on the development of life skills in youth at risk. Objectives The aim of this study was to examine how the experiences lived through BdmB contributed to the development of life skills in young adults who have participated in the programme between 2001 and 2009, and how they transferred these life skills in their everyday life. Methods We used a retrospective qualitative study design. Semi-structured interviews (mean length = 90 min) were conducted with 14 young adults (mean y. o. = 22) who were involved in the BdmB programme during their high school. Interviews were audiotaped and transcribed verbatim. Analysis was guided by the grounded theory approach (Glaser & Strauss, 1967). A thematic multilevel (vertical and horizontal) content analysis of participants' accounts was performed to identify the specific role of team sport involvement with psychosocial interventions on the alumni players' life skills development, and its transfer to their everyday life in post-intervention. Results Group interactions and social workers' interventions were significant factors in the improvement of life skills. The sense of belonging to the programme also seemed to have contributed to this development. Moreover, BdmB was perceived as a protection to the negative influences in their living environment. However, the maintenance of these improved skills appeared to be influenced, positively and negatively, by post-high school interactions with the social environment. Conclusions While team sport appears to be a favourable context for the development of life skills in youth, the psychosocial interventions represent a key factor in this development. Furthermore, their maintenance seems to be influenced by the "quality" of the social environment during post-high school period. ## JAPANESE SWIMMING EDUCATION FOR THE FOLLOWING GENERATION -A COMPARISON WITH WATER SAFETY EDUCATION IN NEW ZEALAND-

MORISHITA, A., TORIUMI, T., HARUKI, T., FUJIMOTO, H., ISHIDE, Y.

KEIO UNIVERSITY

**Introduction** In Japan, more than 90% of the elementary and junior high schools have swimming pools, and the schools hold swimming classes as part of physical education in accordance with the teaching guidelines. However, deaths due to water accidents are the highest in Japan among all the OECD countries (WHO, 2004). The above mentioned Japanese swimming classes have low effectiveness in decreasing deaths caused by water accidents in Japan (Toriumi et al., 2009). To consider the purpose of swimming education for the following generation, it is important to compare Japanese swimming classes with such classes in other countries. New Zealand is one of the countries with a successful system for swimming and water safety education (Moran, 2009; Moran, 2010). Thus, we conducted interviews to understand swimming and water safety education in New Zealand. Methods The author and co-author visited various facilities related to water safety in Auckland, the capital of New Zealand. The following sites were visited: (1) Auckland University, faculty of education, (2) Water Safety Auckland Inc., (3) Surf Life Saving, (4) Coastguard Service/Maritime Police. Results Water safety education in Auckland is often held in natural environments, such as rivers and lakes, as it is difficult to prevent water accidents in such environments. However, teachers and trainers utilize guidelines that water safety companies and researchers have created to ensure safety during swimming classes held in such environments. Water safety companies and researchers study and summarize aspects of water safety every year, and teachers and trainers study these results to ensure safety during swimming classes held in natural environments. Discussion This system of reciprocity between water safety research and education in Auckland is one reason why New Zealand's mortality rate due to water accidents is lower than that of Japan. In Japan, such a reciprocal system does not exist, and water safety education is seldom held in natural environments because the number of such environments is limited, and most natural environments are equipped to protect people from water accidents. ## POLISH FENCERS AS AN ATHLETES SITUATED BETWEEN AMATEURISM AND PROFESSIONALISM

KUCHARSKA, A.

THE UNIVERSITY SCHOOL OF PHYSICAL EDUCATION IN WROCLAW

**Introduction** The purpose of this study was to establish what kind of sport's model is represented by Polish Fencers. To analyze this issue, Zbigniew Krawczyk's theory (1995) was used. In his concept there are four models of modern sport (complete amateur sport, not complete amateur sport, not complete professional sport, complete professional sport). This typology is based on the economic factor, which is a main stimulator of athletes sport activity (Krawczyk, 1995). The next step was to investigate, which dimension of competitive sport (Heinemann, 1989) is the most important for respondents. To achieve this goal respondents were asked about the most important thing for them in fencing. Possible dimensions of competitive sport, like bodily, sporting, intellectual, social, economic, esthetic and a mix of them were taken into account (Heinemann, 1989). The amateurism can be treated as a sociological problem (Gruneau, 2006). Methods This research was conducted with 100 polish fencers (47 women and 53 men). The largest group (68%) was represented by seniors (21 years old and more). Rest of respondents were juniors (18-20 years old) - 25% and cadets (15-17 years) - 7%. An average competitive experience was 10,7 years. The diagnostic pool was used. Questionnaire had both close and open questions. The purposive sampling (Babbie, 2004) technique was used in the selection of the sample. The research was conducted during Polish Seniors Championship in 2009. Collection of data have taken two days. The SPSS program was used to process data and statistical analysis. Results and Discussion Most of the respondents were representing a model which is between "not complete amateur sport" and "not complete professional sport". Respondents declared, that in fencing, victory was most important for them (95%). It means that sport dimension is the most important for Polish fencers. This was admitted by 100% women and 90% men. The research also emphasize the economic dimension

as similarly important. Stipends and awards are crucial for 62% of respondents. It is worth to remember that these are theoretical models. In reality, the situation of amateur athletes is more complicated. The meaning of economic factor increases with the athletes professionalism, even if these athletes in theory are amateurs. ## THE RELATIONSHIP BETWEEN SOCIAL COMPARISON AND COACHES' ORIENTATION TOWARDS COMPETITIVE SITUATION

SIMION-DUMITRIU, D.

*NATIONAL SCHOOL OF POLITICAL SCIENCES AND PUBLIC ADMINISTRATION*

**Introduction** How coaches behave depends on the representation they have towards their role and towards the competitive situation itself. Therefore, the aim of this study is to analyze the relationship between the coaches' orientation towards the competitive situation and the way they define their role in relation to the competitors. Based on combining conceptual elements from social dramaturgy, achievement goal theory and social comparison theory, the study outlines the main perspectives on sports field from the view point of the coaches' social representations upon sport context and actors. **Methods** The qualitative approach is based on semi-structured interviews with handball coaches from the first and the second professional leagues from the Romanian Feminine Handball Championship. **Results** The results show that the dominant orientation in defining the competitive situation is the goal orientation and the differences between self-improvement and domination type of goal orientation is based on the nature of social comparison the coaches' use towards their competitors. **Discussion** When faced with a downward or lateral comparison, coaches tend to use an orientation to domination, while in case of upward comparison they prefer a self-improvement goal orientation to minimize the impact of the competition result on the level of self-esteem. Moreover, the balance between social and temporal comparison is strongly influenced by contextual factors, among which the evaluation of the competitor and of the winning chances are the main ones.

## TO LEAVE A 'SPORTING LEGACY'? THE DEBATES ON INCREASING GRASSROOTS SPORTS PARTICIPATION OF HOSTING THE 2012 LONDON OLYMPIC GAMES

LEE, P., JIANG, R.

*NATIONAL TAICHUNG UNIVERSITY OF EDUCATION, LOUGHBOROUGH UNIVERSITY*

**Introduction** This discussion is about the potential impacts of the Olympic Games and primarily about debates on increasing grassroots sports participation of hosting the 2012 London Olympic Games in UK. **Methods** The documentary-based element takes the form of qualitative content analysis, which applied to the form of analysis of a number of British sport official reports, academic articles, and media commentaries in the 2008-10 period. In total, 107 documents were reviewed and 53 commentaries were identified to conduct this research. The data was subject to analysis and coding employing the NVivo 8 software package. **Results** The 'predicted or claimed' benefits of increasing grassroots sports participation from the 2012 Olympic Games may not be as large as expected. Arguments from governmental sectors or academic research are divided. As attitude toward the potential impacts on increasing grassroots sports participation, the number of pessimists and optimists both rose slightly, though optimists (51.2 %) still outnumbered pessimists (48.8 %). **Discussion** The relatively even split indicates that the uncertainty of how much increased grassroots sports participation can be generated by the 2012 London Games. Indeed, the promise of increased sports participation was central to London's successful bid to host the 2012 Games. However, hosting a major sporting event is actually one factor among many that has an impact upon grassroots sports participation rather than being a direct causal motivator in and of itself (Weed et al., 2008). Interestingly, those specific elite sport developing programs have invited criticisms from various actors such as charities, arts grass roots sport which are already suffering a decrease in income because of the financing of the Games. Thus, it's hard to claim what extent the grassroots sports participation would be boosted/increased by hosting the 2012 Olympic Games. **References** Weed M., Coren, E, Fiore J. (2008). A systematic review of the evidence base for developing a physical activity, sport and health legacy from the London 2012 Olympic and Paralympic Games, 1-127. ## SPORT ORGANIZATIONS THAT DELIVER YOUTH SOCCER: SAME COMPETITION, DIFFERENT MODELS?

SANTOS, A., GONÇALVES, C.E.

*FCDEF-UC (COIMBRA, PORTUGAL)*

**Introduction** The clubs are important to sport offer and promotion, being responsible for the individual's organized sports participation. They provide conditions for athlete's development and the involvement of significant others in sport and, as organizations, they transmit their organizational culture. It is believed that this ecology of practice can influence the way athletes and communities perceive their sport experience. The aim of this study is to identify the soccer clubs model of organization, their culture, goals and answers to the demands of the surrounding environment. **Methods** Three Portuguese soccer clubs were analyzed, in different contexts. One professional club (PC) and two amateurs (AC) of regional level (one of rural area RAC, other of urban area UAC). A documental analysis of the clubs was performed. Semi-structured interviews with presidents in AC and, with the manager of youth specialization department in the PC were made. To analyze the interviews content analysis was used. **Results** The AC seems to be homogeneous among themselves and heterogeneous in relation to PC. The PC contains more formalized, specialized, complex and orientated to performance operating principles. That is verifiable by a structure with specialization of function and personnel. The AC present a much more simple structure, low formalizing and bureaucracy, which suggest a strong centralization. Their declared goals are related to community and local development. Both refer difficulties in hiring and securing collaborators. **Discussion** The results about structure, human resources and goals fit with those of previous studies (Papadimitriou, 2002; Nichols, Gratton, Shibli, & Taylor, 1998). The PC, by its way of function, holds a more prepared and solid position, provides better conditions to sports development, disassociating itself from the organizational style of UAC and RAC. The

PC orientation to performance results, may lead to promotion of anti-social and anti-ethical attitudes and values in the athletes (Rocha & Turner, 2008). The AC, despite their less complexity, foster a greater sense of community and confidence, as well as a greater pleasure and opportunities to health improvement (Institute for Volunteering Research, 2007). ## THE INTERGRATIVE STUDY OF RECREATION INDUSTRY IN PING-TUNG REGION OF TAIWAN

CHANG, KUANG-MING 1, TING, WEN-CHI 2, CHENG, CHINE-MIN 3

1 : TJUIPINGTONG, TAIWAN/, 2 : CSU (KAOHSIUNG, TAIWAN) 3 : KUAS (KAOHSIUNG, TAIWAN/).

**Introduction** The development of recreation industry has gathered great importance in recent years, especially in Ping-Tung region, Taiwan. With the increasing usage of recreation, government's requirements for recreation planning have become more critical. The purpose of this study was to determine if the use of leisure theory would improve the recreation industry of Ping-Tung area in Taiwan. **Methods** This study adopts the Delphi Method to integrate the leisure theory and the opinions of experts from the enterprise, the authority, and relevant academic fields through questionnaire survey, in order to construct an integrative study between recreation enterprise and policy, and thus the integrative model emerged from the Ping-Tung recreation enterprise and policy oriented mechanism is to meet the challenges and to adjust policy enforcement. **Results** By the way of analyzing the recreation industry of Ping-Tung region, there are some conclusions as followings: 1. The plan of public administration: (A) To integrative the justice and rational recreation industrial policies. (B) To establish internationalization, liberalized and competition recreation industrial policies. (C) To take this profit (I/O) as the execution basis of recreation industrial policy. 2. Leisure administration organization achievement: (A) To ponder five W-Hs. (B) To use SWOT. (C) To considerate the legal relationship. (D) To construct the problem solving patterns. (E) To adopt the management by objectives. 3. The future administration organization models: The Ministry of Transportation and Communications should set up the standard rules including the tourist, the tourism management, the environment and the traveling security. **Discussion** The development of recreation industry is a reflection of society patterns and life quality, and government's recreation planning with relevant service behaviors has educational implication and manifests value judgment. The value of the study lies in highlighting the government's planning and management, which will determine the efficacies of customer experience, inclusive of economic, and non-economic efficacies; economic efficacy refers to the use of expenditure amount to measure the service value of recreation industry, whereas non-economic efficacy refers to the emphasis of patterns of consumption and recreation to fulfill educational implications and behavioral changes. ## ASSESSMENT OF FUNCTIONS OF SPORTS IN TERMS OF INTERNATIONAL RELATIONS

ALGUN DOGU, G., SUNAY, H.

*MEDICINE SCIENCE*

**Introduction:** This research has aimed reveal whether some of the reference groups that have given a shape to sport use it as a means of an objective of foreign policy at the international relations or not. The research group consists of 57 members of parliament, 32 federation chairmen and federation secretary, and 51 academicians, total 140 persons. **Methods:** As a means of data collection; "International Relations and Sport Interaction Survey" was used. After survey factor analysis was completed, it has been divided into three dimensions (political, economic, and military). The views of these persons have been examined through the personal variants. These variants are age, seniority and education. At the data analysis t-test and at the groups more than two unidirectional variances analysis (Anova), and at settling in which groups there is a difference Tukey statistic techniques were used. At the research,  $p < 0.05$  relevance level has been the base. **Result and discussion:** In the wake of the research, when the data of the ones taking part in the study on International Relations and sport Interaction (academic personnel, federation chairman, federation general secretaries and members of parliament) has been examined according to their ages, age 31 and underneath, between 31-40, up-40 economic means consequences respectively; %12.0, %55.1, %32.9, political means consequences; %11.9, %54.9, %33.2, military means consequences; %11.2, %57.9, %30.9. When the data has been examined according to the seniority, age 11 and underneath, between 11-20, up-20 economic means consequences respectively; %16.3, %60.8, %22.9, political means consequences; %16.1, %60.4, %23.5, military means consequences; %15.9, %63.1, %21.0. When the data has been examined according to the education, undergraduate and master, economic means consequences respectively; %28.5, %71.5, political means consequences; %28.3, %71.7, military means consequences; %27.9, %72.1. Among the reference groups that have taken part in the study in Turkey, sport is used for a political tool in the international relations mostly. References: SUNAY, H. (2010) *Organization in Sport*. ## SPORTS SERVICES IN TIRANA: CUSTOMERS' SATISFACTION OF TOWARDS SERVICE QUALITY OF FITNESS CENTRES

LALAZI, Y., LILE, A., RIZVANOLLI, V.

*UNIVERSITY OF SPORTS OF TIRANA*

**Abstract** Lalazi, Y.1, Lile, A.1, Rizvanolli, V.1, 1: UST (Tirana, Albania) **SPORTS SERVICES IN TIRANA: CUSTOMERS' SATISFACTION OF TOWARDS SERVICE QUALITY OF FITNESS CENTRES** **Introduction** Sports and leisure service is an emerging field in Albanian marketplace. The sport product is a complex package that offer bundles of benefits to satisfy customer wants and needs (Mullin, Hardy, & Sutton, 2007). As competition among the fitness centers is increasing, customers' satisfaction becomes an integral part in the sport business. The aim of this study was to investigate and recognize elements of sport services that contribute to enhance the service quality in sports and leisure, in Albania context. **Methods** This study was focused on analyzing sport services in Tirana comprising to stages: Stage1) General overview of Sport Services in Tirana, where the data was gathered from the Municipality tax office; Stage 2) Measuring Customer Satisfaction using SERVQUAL service quality (Parasuraman, Zeithamal, & Berry, 1991). Participants in this study were 120 members randomly selected from 3 fitness centres in Tirana. 96 out of 120 members responded. The data for this study were gathered over a 7-week period using questionnaires. SERVQUAL was the instrument used in this study- a perceived service quality questionnaire which examines five dimensions of service quality: Reliability, Responsiveness, Assurance, Empathy, and Tangible. SPSS 17.0 was used for statistical analyses. Results There

are currently 60 private activities operating in the sport field from 2001 to 2010, classified in sports complex (30%), gym(38%) and fitness centers (32%) in Tirana, where (77%) are small business and (23%) are big ones. The highest satisfaction level was placed on the 'empathy' dimension, followed by 'assurance', 'tangibles', 'reliability' and 'responsiveness' respectively. Two-ways statistical ANOVA analyses were conducted and revealed four statistically significant differences between "actual" and "preferred" scores for the 'assurance', 'tangibles', 'reliability' and 'responsiveness' scales. Results revealed large F-ratios for 'tangibles' (3.661), 'reliability'(4.883) and 'responsiveness' (3.879) scales. Discussion Results revealed that the customers' satisfaction was at the average level in overall aspects (2.89), and sport business should invest more in this direction. Support on the items of critical scales ('tangibles', 'reliability' and 'responsiveness') should be improved to increase service quality perception. Future studies may extend this research through increasing the customers participation in the survey and adding other criteria in parallel with changes in the sport field. ### PP-TH02 Altitude Hypoxia 2

#### EFFECTS OF ACUTE NORMOBARIC MODERATE HYPOXIA ON FATIGUE AND STEADINESS DURING SUBMAXIMAL ISOMETRIC CONTRACTIONS

WILLEMS, M.E.T., BRUSH, T.I.

UNIVERSITY OF CHICHESTER

Introduction Acute hypoxia alters fatigue of isometric contractions of skeletal muscles (Goodall et al., 2010) and is associated with changes in electromyographic responses (Katayama et al., 2007). Muscle fatigue during sustained isometric contractions results in an increase in force fluctuations, i.e. a decline in steadiness. Neuromuscular responses during hypoxia may influence fatigue and steadiness of skeletal muscles. We examined the effect of acute normobaric moderate hypoxia on the performance of isometric contractions of skeletal muscles. Methods Ten (8 male, 2 female) subjects (23±3 yr, 78±8 kg, 179±8 cm) volunteered. Subjects breathed normoxic (N, FIO<sub>2</sub>: 21%) or moderate hypoxic (H, FIO<sub>2</sub>: 14%) gas mixtures providing arterial oxygen saturation of 98% and 88%. Familiarized subjects produced maximal voluntary isometric force (MVIF) of m.quadriceps femoris (knee angle 90°), a 20%MVIF until force fell below 18% for 3 s and 20 seconds after completion of the 20%MVIF a measurement of MVIF to quantify fatigue. Steadiness during 20%MVIF was quantified by the coefficient of variation (SD/mean x100). Surface EMG (Bagnoli-2, Delsys) of m.vastus lateralis and m.vastus medialis was recorded and analysed for root mean square (RMS) and median frequency (MF). Data were analysed with 2-way ANOVA and paired t-tests with significance set at P<0.05. Results There were no differences between conditions for force of maximal voluntary contractions (N: 565±116 N, H: 540±187), steadiness (N: 6.9±2.0; H: 6.3±1.7), time to fatigue (N: 358±97 s, H: 357±112 s), and fatigue index (N: 40±19%, H: 41±16%). In the hypoxic condition, changes in RMS during 20%MVIF were lower in m.vastus medialis but not in the m.vastus lateralis (n=9). During 20%MVIF, there was no change in MF of the m.vastus medialis in both conditions but similar decreases in MF for the m.vastus lateralis (n=9). Discussion Moderate hypoxia did not affect time to fatigue during a sustained 20% isometric force which may be due to partial occlusion of blood flow at this intensity (Sejersted et al., 1984) resulting in similar muscle oxygenation levels in both conditions during fatigue testing. Neuromuscular responses to acute normobaric hypoxia were different for muscles of the m.quadriceps femoris with the level of activation higher during normoxia for m.vastus medialis but without effect on steadiness. Peripheral mechanisms contributing to isometric fatigue of submaximal sustained contractions during moderate hypoxia may be muscle-dependent. References Goodall S, Ross EZ, Romer LM. (2010). #### EFFECTS OF TIMING FOR HYPOXIC EXPOSURE ON GROWTH HORMONE RESPONSE AFTER RESISTANCE EXERCISE

KUROBE, K., HUANG, Z., NAGIRA, A., YAMAMOTO, M., TAKEKURA, H., OGITA, F.

NATIONAL INSTITUTE AND FITNESS AND SPORTS

Introduction Previous studies (Kurobe 2010) have reported that when resistance exercise is performed in hypoxia, growth hormone (GH) secretion after exercise is further increased compared to that after the same exercise is done in normoxia. However, it has not been clarified whether the greater GH secretion after exercise is affected by timing for the hypoxic exposure, i.e. hypoxic exposure from pre-exercise, or only after the exercise. Therefore, the present study aimed to examine the effects of the timing for hypoxic exposure on GH response after resistance exercise. Methods Twenty-one healthy male adults (23±1 yrs) were matched for exercise capacity level into three groups, and then randomized to normoxic group (N; n=7) and 2 hypoxic groups (H1; n=8, H2; n=6). H1 was exposed to hypoxic condition (O<sub>2</sub> 12.7%) from pre-exercise (30 min) to recovery period (60 min) through the experiment, and H2 was exposed to the same hypoxic condition only after the exercise (i.e. during recovery period). They performed elbow extension exercise at the workload of 10 repetition maximum (RM) to the exhaustion in each set, and it was repeated 3 sets with 1 min rest between sets. Blood samples were obtained before exercise and during post-exercise recovery period (immediately, 15, 30, and 60 min after the exercise) to determine blood lactate (LA), serum GH, serum cortisol concentrations. Results In each group, LA values at immediately and 15 min after the exercise were significantly higher than that at pre-exercise (P<0.05). In the comparison among the groups, there were no significant differences in LA values through the experiment. GH during recovery period was significantly increased only in H1 but not in N and H2, when compared to that at pre-exercise (P<0.05). Furthermore, when GH during recovery period was compared among groups, the values at immediately and 15 min after the exercise in H1 were significantly higher than those in H2 (P<0.05). Also, GH at 60 min in H2 was significantly higher than that in N (P<0.05). Cortisol in N was significantly decreased at 60 min compared to that at pre-exercise (P<0.01), while no significant changes were found in H1 and H2 throughout the experiment. Discussion/Conclusion Our results indicate that even in hypoxic exposure only after the exercise, GH secretion is enlarged when compared to that in normoxia, but that GH secretion is further enlarged when the hypoxic exposure is done from pre-exercise to recovery period. Therefore, it is suggested that the timing for hypoxic exposure would affect GH secretion after the exercise. Reference Kurobe, K., et al. (2010) Effects of resistance training in hypoxic condition on muscle hypertrophy and muscle strength. Book of Abstracts, 15th Annual Congress of ECSS: 357.

## EFFECTS OF INTERMITTENT HYPOBARIC HYPOXIC EXERCISE OF 5 DAYS ON BLOOD PRESSURE AND VASCULAR ADAPTATIONS

OGITA, F.1, KUROBE, K.1, HUANG, Z.1, OZAWA, G.1, NAGIRA, A.1, NISHIWAKI, M.1, TANAKA, T.1, TAKEKURA, H.1, TAMAKI, H.2

1: NATIONAL INSTITUTE OF FITNESS AND SPORTS, 2: NIIGATA UNIVERSITY OF HEALTH AND WELFARE

**Introduction** Recently, we have observed that aerobic exercise in hypobaric hypoxia of 4 weeks could induce beneficial circulatory adaptations, such as a reduction of total peripheral resistance and blood pressure, and an increase in flow mediated vasodilation (FMD) response, stroke volume and cardiac output (Ogita 2008). However, it has not been clarified whether such cardiovascular adaptations can be obtained within a relatively short training period. Therefore, the present study aimed to examine the effects of intermittent hypobaric hypoxic exercise of 5 days on blood pressure and vascular adaptations. **Methods** Sixteen healthy male adults (23±1 yrs) were matched for physical fitness level into two groups and then randomized to normobaric normoxic exercise group (N, n=8) and hypobaric hypoxic exercise group (H, n=8). The aquatic exercise training was done in a swimming pool located in a chamber where atmospheric pressure could be regulated. The exercise was performed at the intensity of 50%VO<sub>2</sub>max level for 30 minutes/training session for consecutive 5 days. H had the exercise in the hypobaric condition corresponding to 2500m above sea level, and was exposed to the condition for 2 hours/session. Before and after the training, systolic (SBP), diastolic (DBP) and mean blood pressure (MBP) were determined at rest and during cycling exercise at 50%VO<sub>2</sub>max. Also, arterial stiffness was assessed by brachial-ankle pulse wave velocity (baPWV), and FMD was evaluated by peak diameter of the popliteal artery during reactive hyperemia, which was measured by ultrasound imaging system. **Results** After the consecutive 5 days training, no significant changes were observed in all measured values for N. For H, SBP, DBP and MBP at rest and during submaximal exercise did not change significantly, either. On the other hand, peak diameter during reactive hyperemia and %FMD tended to increase, and baPWV as an index of arterial stiffness was significantly reduced ( $P < 0.01$ ). **Discussion** These findings suggest that a reduction of arterial stiffness and vascular functional adaptation such as an increase in FMD response could be induced by intermittent hypobaric hypoxic exercise of relatively shorter terms, when compared to the same exercise performed in normoxia, and that the changes in blood pressure would not be necessarily associated with the reduction of arterial stiffness and/or increase in FMD response. **Reference** Ogita, F., et al. (2008) Effects of exercise training at different hypobaric hypoxic conditions on cardiovascular adaptations. Book of Abstracts, 12th Annual Congress of ECSS: 394-395.

## INTERMITTENT HYPOXIC TRAINING TO ENHANCE ATHLETES ENDURANCE

VOLKOV, N.I., POPOV, O.I., VOJTENKO, Y.L., KOLESNIK, O.

RUSSIAN STATE UNIVERSITY OF PHYSICAL EDUCATION AND SPORT

**Introduction** The improvement of sports achievements occurring in the process of swimmers training reflects the process of adaptation under the influence of means and methods used in training. Means and methods used in training of swimmers are differentiated by the direction of physiological influence. Depending of the chosen characteristics of physical loads such as type of exercise its intensity and duration, recovery breaks, number of repetitions; all training loads used in training of swimmers can be divided into the following groups: loads of aerobic effect; loads of combined aerobic-anaerobic effect; loads of glycolytic anaerobic effect; loads of alactate anaerobic effect. Intermittent Hypoxic Training (IHT) has been used as an additional method to enhance effects of different types of training loads. **Methods** Twelve swimmers of high qualification were divided into two groups: control and experimental. The control group was training with usual capacity using traditional techniques. Experimental group of swimmers together with the same traditional methods of training used different variants of IHT during the recovery periods followed the main training loads. Hypoxicator Everest (joint project of Climbi Ltd., Russia and Praxsep Inc., Canada) was used for creating hypoxic atmosphere. Each single hypoxic exposure was 3-10 min followed by 3-10 min rest period when athletes were breathing regular air. Combined exposure did not exceed 1.5-2 hours within one day. The period of experimental training continued for three months. Before and immediately after the end of experiment the athletes of both groups were tested in standard ergonomic procedures for the maximum of aerobic and anaerobic work capacity. **Results** Under the conditions of the given experiment IHT resulted in significant increase in parameters of maximum aerobic capacity for the experimental group: VO<sub>2</sub> max increased on average 11%; VE - 6.4%; Wcr - 10.8%; ΔpH - 44.6%; ExcCO<sub>2</sub> - 23%, and Wmax - 9.8%. **Results** for the control group were significantly lower. **Discussion** According with these findings the greater improvement in swimming performance was to be expected for athletes in the experimental group in middle distances such as 200, 400, and 800 m. The use of IHT as additional training method for qualified swimmers made it possible to considerably improve sports results in short period of training. **References** Viru A. ## PO2 AND PH AFTER DIFFERENT EXHAUSTIVE EXERCISES IN MODERATELY TRAINED ATHLETES.

ZINNER, C.1,2, WAHL, P.1,3, SPERLICH, B.1,2, KRUEGER, M.1,2, HAEGELE, M.1, MESTER J.1,2

GERMAN SPORT UNIVERSITY, COLOGNE

**INTRODUCTION:** There is a lot of scientific evidence about the differences in maximal oxygen consumption between different ramp test and step test protocols. Furthermore the differences in VO<sub>2</sub> between running and cycling are also well investigated. Comparisons between the maximal decline of the partial oxygen pressure (PO<sub>2</sub>) as well as the pH at the point of exhaustion are less investigated. We hypothesized that the pH and the PO<sub>2</sub> after a ramp test protocol will be more reduced than after a step test protocol. **METHODS:** 14 subjects (10 m and 4 w) (24.4 ± 2.1 yrs, 180.7 ± 8.8 cm, 76.3 ± 11.8 kg) participated in the study. All participants completed four different tests to exhaustion with at least four days in between in randomized order. Two tests were step tests with step duration of 5min. Two protocols were ramp test protocols with step duration of 30s after an initial step of 2min. One step and one ramp test was carried out on a cycle ergometer (bike) and on a treadmill (run), respectively. During all tests VO<sub>2</sub> was measured breath by breath (nSpire, Zano 600). Immediately after the tests pH and PO<sub>2</sub> were measured in capillary blood. **RESULTS:** Peak power output were significantly different between all tests except between both ramp tests (bike ramp 362 ± 47; run ramp 361 ± 64; run step 206 ± 56; bike step 255 ± 45). Highest rel.VO<sub>2</sub>peak was reached at the end of the run ramp test (54.8 ± 6.0 ml/min/kg). Lowest rel.VO<sub>2</sub>peak was obtained during the bike step test (45.8 ± 8.8 ml/min/kg). Rel.VO<sub>2</sub>peak during the other two tests was 47.2 ± 9.7 ml/min/kg (bike ramp) and 49.9 ± 7.1 ml/min/kg (run step). The greatest reduction of the PO<sub>2</sub> was detected after the run ramp test (pre vs. post: -3.5 ± 1.8 mmHg). However the only statistical significance was found between the run ramp test and bike step test. The pH showed lower values after both ramp tests than after the

both step test protocols (ramp: run  $7.22 \pm 0.06$ ; bike  $7.23 \pm 0.04$ ; step: run  $7.30 \pm 0.05$ ; bike  $7.26 \pm 0.05$ ). DISCUSSION: Our results are in accordance with our hypothesis. During the ramp test on both ergometers that we used the pH was lower than during the longer protocols (step tests). It seems that during the end of the shorter test protocols the subjects were able to use more glycolytic muscle fibers to achieve higher power and produced more H<sup>+</sup>-ions that weren't metabolized. After the running tests, subjects' PO<sub>2</sub> declined more than after the bike tests. Compared to tests on a cycle ergometer this is due to the higher mass of muscles used during running which need oxygen supply during high intensity exercise.

### EFFECTS OF INTERMITTENT NORMOBARIC HYPOXIA ON AUTONOMIC NERVOUS SYSTEM IN YOUNG MALE ATHLETES

NAKAMURA, M., NEYA, M., OHIWA, N., MATSUBAYASHI, T., HONDA, A., ORIISHI, M., SUZUKI, Y., KAWAHARA, T.

JAPAN INSTITUTE OF SPORTS SCIENCES

**Introduction** The strategy, in which the altitude exposure is combined with intermittent normoxia for training purpose, the so-called "live high-training low" (LHTL) model, has been demonstrated to be particularly effective and is becoming widespread among endurance athletes. Previous studies found that continuous 3-4 weeks exposure to hypoxia cause decreased parasympathetic and increased sympathetic tone. However, it is unknown whether there is similar effect in the intermittent nightly hypoxic exposure (e.g. nightly hypoxic exposure for 10 days – staying at sea level for 5days – nightly hypoxic exposure for 10days) on autonomic nervous system. The purpose of this study was to investigate the effects of intermittent nightly hypoxic exposure on autonomic nervous system in young endurance athletes. **Methods** Eight young male athletes (long distance runner) volunteers participated in the study. All subjects entered the hypoxia-chamber (3,000m) during sleep for 10days, after staying at sea level for five days, and then all subjects entered the hypoxia-chamber (3,000m) during sleep for 10days again. The study consisted of four phase: the pretesting phase, the first continuous 10days hypoxia-chamber exposed phase, after staying at sea level for 5days, and post-testing (after second continuous 10days hypoxia-chamber exposed) phase. Subjects abstained from caffeine and fasted for at least 12h before each test and all data were collected every morning between 7:00 and 9:00 a.m. in the three phases. In the supine position, resting heart rate (HR) and beat-by-beat blood pressure (BP) were measured. Beat-by-beat BP was derived by radial artery tonometry (Jentow7700; Nihon Colin, Komaki, Japan). After a10min resting period, we measured time and frequency domain parameters of resting HR variability (HRV) and spontaneous baroreflex sensitivity (SBRS). To assess HRV and SBRS, we applied the power spectral analysis and sequence method, respectively. Results We found no significant differences in indexes of HRV and SBRS between pretesting and post-testing phases in young male athletes. The influence of staying at sea level for 5 days in indexes of HRV and SBRS were not observed. **Conclusion** These results suggest that the intermittent nightly normobaric hypoxia do not affect the autonomic nervous system in young endurance athletes.

### VALIDITY OF THE JÄEGER OXYCON-PRO® EXPIRED AIR ANALYZER IN NORMOBARIC HYPOXIA

HOLLISS, B.1,2, PEDLAR, CH.2, GLAISTER, M.2

(1): UNIVERSITY OF EXETER, EXETER, UK, (2): ENGLISH INSTITUTE OF SPORT, MANCHESTER, UK. (3): ST MARY'S UNIVERSITY COLLEGE, TWICKENHAM, UK

**INTRODUCTION:** When utilising a high precision O<sub>2</sub> analyser, the closed-circuit Douglas Bag Method (DBM) arguably provides the 'gold standard' estimation of oxygen uptake (VO<sub>2</sub>) (Macfarlane, 2001). However, open-circuit breath-by-breath analysers give greater insight into the physiological conditioning of athletes, so are now commonplace in exercise science laboratories worldwide. One such unit, the Jäeger Oxycon-Pro® (JOP) provides valid and reliable estimates of VO<sub>2</sub> in normobaric normoxia (NN) (Foss & Hallen, 2005), but there are no published data regarding the performance of the JOP in normobaric hypoxia (NH). **PURPOSE:** To investigate the validity of the JOP in NH. **METHODS:** 10 physically active males ( $29.4 \pm 7.1$  y,  $74.9 \pm 5.2$  kg) completed two identical cycling tests; one in NH (fraction of inspired oxygen (FIO<sub>2</sub>) =  $16.0 \pm 0.1$  %), and one in NN (FIO<sub>2</sub> =  $20.9 \pm 0.1$  %), separated by 1-2 days, in a randomized order. The JOP was calibrated using a modified procedure, involving feeding the ambient air intake with bottled NN air. Participants cycled at 120 W for 4 consecutive 4 minute stages, while VO<sub>2</sub> was estimated from expired air using the JOP and DBM. VO<sub>2</sub> was estimated over 60 s intervals, twice by each analyzer, in an alternating, randomized order, then repeated at 160 W. Correlation coefficients were estimated using linear regression analyses, and standard error of the estimate and coefficient of variation (CV) were calculated. **RESULTS:** Linear regression analyses revealed VO<sub>2</sub> agreement between the 'criterion' DBM with the JOP estimations: correlation coefficients in NN were  $R^2 = 0.70$  at 120 W, and  $0.85$  at 160 W, and in NH  $R^2 = 0.74$  at 120 W, and  $0.82$  at 160 W. The statistical comparison between the JOP and DBM in NN gave a CV at 120 W of 5.0% (95% likely range: 3.4 to 9.8%), and at 160 W a CV of 3.3% (95% likely range: 2.2 to 6.3%). In NH, the CV was calculated at 120 W as 4.3% (95% likely range: 2.9 to 8.4%), and at 160 W as 3.1% (95% likely range: 2.1 to 6.0%). **CONCLUSION:** The JOP performed well in both NN and NH, providing a more valid estimation of VO<sub>2</sub> in NH than in NN. Further investigations should be conducted to establish this validity at higher ventilatory rates, either using participants with greater lung capacities, or using an 'automated pulmonary simulator' (Gore et al, 1997). **REFERENCES:** Foss, O. & Hallen, J. ### EFFECT OF HYPEROXIC-SUPPLEMENTED INTERVAL TRAINING ON ENDURANCE PERFORMANCE IN TRAINED CYCLISTS

KILDING, A.E., WOOD, M., SEQUIRA, G.

AUT UNIVERSITY

**EFFECT OF HYPEROXIC-SUPPLEMENTED INTERVAL TRAINING ON ENDURANCE PERFORMANCE IN TRAINED CYCLISTS** Kilding, A.E., Wood, M., Sequira, G. Sport Performance Research Institute New Zealand, AUT University, Auckland, New Zealand **Introduction** Inspiring a hyperoxic gas mixture while performing prolonged intense exercise allows higher power outputs to be achieved, both acutely (Welch 1987) and chronically (Perry et al 2005;2007), compared with breathing normoxic air. However, while it has been clearly demonstrated that higher power outputs can be maintained with hyperoxic training, and plausible mechanisms exist supporting its efficacy, evidence of performance enhancement following hyperoxic training in athletes is unclear. The aim of this study was to determine the effect of hyperoxic-supplemented interval training on endurance cycling performance. **Methods** Using a single-blind, randomised control-trial design, 16 well-trained cyclists were randomly assigned to either an experimental group that trained in hyperoxia (HYP, FIO<sub>2</sub>=0.60), or a sham HYP training group that trained in normoxia (N, FIO<sub>2</sub>=0.21). Participants visited the laboratory twice per week, for four weeks, to perform supervised high-intensity interval training sessions in HYP or N. A range of tests were performed pre- and post-intervention including: 1) a 20 km time-trial; 2) an incremental step test for determination of VO<sub>2</sub>peak and lactate threshold (LT); and 3) a 60s all-out test. Heart rate

and power output were measured during all sessions. Results Small effects on most physiological measures, including  $\text{VO}_{2\text{peak}}$  ( $1.9 \pm 4.3\%$ ) and LT ( $0.3 \pm 8.3\%$ ), were observed after HYP. In most instances, physiological changes in N were greater than in HYP. There was a small increase in mean power during the 20 km time-trial in HYP ( $2.1 \pm 3.7\%$ ) but this was less than that observed in N ( $4.9 \pm 3.9\%$ ; ES:  $-0.44 \pm 0.60$ ). During the 60 s all-out test, the peak relative power was slightly reduced after HYP ( $-0.4 \pm 1.3\%$ ), but not after N ( $0.3 \pm 1.6\%$ ; ES:  $-0.24 \pm 0.76$ ), whereas there was a tendency for mean relative power to be increased in N ( $2.3 \pm 3.4\%$ ), but not HYP ( $0.3 \pm 1.2\%$ ; ES:  $-0.34 \pm 0.49$ ). Discussion Hyperoxic-supplemented interval training in the competitive season had less effect on endurance and anaerobic cycling performance and physiological measures in trained endurance cyclists compared to interval training in normoxia. Despite higher power output during training, the use of hyperoxic-supplemented training at sea-level appears to be not worthwhile for competitive endurance athletes. ### OPTIMAL TIMING OF ALTITUDE TRAINING

WACHSMUTH, N.B., VÖLZKE, C., HOFFMANN, J., SCHMIDT, W.

UNIVERSITY OF BAYREUTH

Introduction: Altitude training is generally accepted to improve sea level performance. The optimal time lapse, however, between return from altitude and best performance has not been systematically investigated. The aim of this project, therefore, was to determine performance after altitude training with two different approaches in order to give recommendations for the optimal timing of altitude training before important competitions. Study I - Methods: Total haemoglobin mass (Hb-mass) of 45 elite swimmers had been measured over a period of two years using the optimized CO-re-breathing method. 25 of the athletes participated between 1 and 3 times at classical altitude training camps, which lasted 3 to 4 weeks, at 2300m. All competition results of this 2-yr period (in total 886 results, 135 within 5 weeks after return from altitude) were converted into the official German point system (world record = 1000 points) and were analysed based on a covariance mixed model. Results: While no effect of altitude training occurred until 3 weeks after return to sea level, a positive effect (+42 pts) was detected 25-35 days after returning ( $p < 0.001$ ). Significant effects were also found for changes in Hb-mass ( $+0.34$  pts/g Hb,  $p < 0.001$ ) and a negative effect was observed 2 weeks after illness and injury ( $-38$  pts,  $p < 0.001$ ). Study II - Methods: In order to check the results of the 2-year study, 10 elite swimmers participated at a 3-week conventional altitude training at 2300m and at a 3-week sea level training camp 5 weeks after returning from altitude. Emphasis was placed on Hb-mass measurement and on standardized performance tests. Four swimmers completed the whole set of swimming step tests (4 tests before, 3 at altitude, and 8 after the altitude camp). The test consisted of 5 200m-steps in the individually chosen swimming style with decreasing time ( $-6$ sec/step) up to the individual maximal speed. For submaximal performance the speed was calculated for fixed [Lac] (4, 6, 8, and 10mmol/l). Results: Hb-mass significantly increased one week after altitude training ( $4.4 \pm 4.4\%$ ,  $p < 0.05$ ). It returned to base line values within the following 4 weeks and was not affected by the sea level training camp. Maximal and submaximal performance clearly decreased at altitude (max speed  $-3.1 \pm 1.9\%$ ,  $p < 0.05$ ), continuously increased until 3 weeks after return ( $+2.8 \pm 1.6\%$ ,  $p < 0.05$ ), and remained at that level for the following weeks. No relationship could be detected between changes in Hb-mass and performance. However, the athletes with the highest response in Hb-mass also showed best performance after a delay of two weeks. Conclusion: Both the long and the short term approach coincide in their results. Best swimming performance was observed 3-5 weeks after returning from altitude training which should be considered when planning an altitude training camp.

### PP-BN15 Performance and Coaching Analysis

#### QUANTITATIVE ANALYSIS OF OFFENSE TRANSITION IN HANDBALL GAMES

ICHIMURA, S., MORIGUCHI, T.

TOKYO UNIVERSITY OF SCIENCE

Introduction It was reported that the handball is becoming speedy and high intensity (Aagaard, Hergeirsson). Recently, it is very important the offense transition after getting a ball. In this study, we evaluated the differences of offense transition aspects between Japan and European teams, to quantitative analyze the offense transition aspects. Methods 1210 offense transitions, from 15 games of 6 teams (NOR, ROU, HUN, JPN, TUN, CHI) participating in the Preliminary Round Group C of 19th Women's World Handball Championship 2009 in China, were analyzed. The offense transition was divided by no fast break and fast break (FB). FB was categorized as 1st wave, 2nd wave or 3rd wave. Furthermore, the results of categorized FB were classified with a successful attack with shot or unsuccessful attack, including offense error, a defended attack or an own discontinuation. The result of the successful attack with shot also was recorded as success or failure shots. Results The numbers of a gotten ball, as successful defense, per a game were  $45.4 \pm 6.7$ ,  $46.2 \pm 13.8$ ,  $42.8 \pm 17.1$ ,  $37.4 \pm 6.2$ ,  $37.4 \pm 12.3$  and  $32.8 \pm 6.4$  in NOR, ROU, HUN, JPN, TUN, CHI, respectively. The rates of FB, including 1st, 2nd and 3rd wave, against the gotten ball were  $75.2 \pm 9.8\%$  in NOR,  $70.8 \pm 15.3\%$  in ROU,  $73.9 \pm 15.2\%$  in HUN,  $62.9 \pm 8.1\%$  in JPN,  $62.3 \pm 15.5\%$  in TUN,  $61.8 \pm 14.7\%$  in CHI, respectively. The rate of FB against the gotten ball in JPN was small tendency compared with that in NOR and ROU. The rate of successful attack with shot against the gotten ball was smaller in JPN ( $31.1 \pm 8.6\%$ ) than in NOR ( $47.4 \pm 7.2\%$ ,  $p < 0.05$ ) and ROU ( $43.4 \pm 18.0$ ,  $p = 0.1$ ). The rate of 1st wave against the gotten ball in JPN ( $10.5 \pm 11.1\%$ ) was smaller than that in NOR ( $28.7 \pm 12.2\%$ ,  $p < 0.05$ ) and ROU ( $26.1 \pm 18.5\%$ ,  $p < 0.05$ ). In contrast, the rates of 2nd wave against the gotten ball were greater in JPN ( $27.9 \pm 5.0\%$ ) than in NOR ( $19.7 \pm 5.5\%$ ,  $p < 0.05$ ), ROU ( $10.6 \pm 4.0\%$ ,  $p < 0.05$ ), HUN ( $19.2 \pm 5.4\%$ ,  $p < 0.05$ ) and TUN ( $19.5 \pm 7.3\%$ ,  $p < 0.05$ ). There were similar in the rate of successful attack with shot and successful shot against the gotten ball in 2nd wave among six teams. The rates of unsuccessful attacks against the gotten ball in 2nd wave were greater in JPN ( $16.0 \pm 6.5\%$ ) than in NOR ( $7.8 \pm 4.9\%$ ,  $p < 0.05$ ), ROU ( $3.9 \pm 1.6\%$ ,  $p < 0.05$ ), HUN ( $8.2 \pm 2.9\%$ ,  $p < 0.05$ ) and TUN ( $9.1 \pm 3.3\%$ ,  $p < 0.05$ ). In the 3rd wave, the rate of goal in 3rd wave against the gotten ball was smaller in JPN ( $5.1 \pm 3.0\%$ ) than in NOR ( $9.5 \pm 6.5\%$ ,  $p < 0.05$ ), ROU ( $12.1 \pm 4.8\%$ ,  $p < 0.05$ ). Conclusion In JPN, the FB frequency was not only small but also the rate of successful attack with shot was small, compared with EUROs. The 1st wave frequency in JPN was smaller than EUROs. The unsuccessful attack frequency during 2nd wave was greater in JPN although JPN had more attacked using the 2nd wave during fast break compared with EUROs. This inefficient attack in JPN was caused by defended attack or an own discontinued attack. The 3rd wave attack was more affected in EUROs than JPN.

## MATCH DEMANDS OF FUTSAL PLAYERS DURING A TOURNAMENT

DOGRAMACI, S., WATSFORD, M., MURPHY, A.

UNIVERSITY OF TECHNOLOGY, SYDNEY

**Introduction** Coaching teams for multiple games in a short time period such as a tournament situation is different from coaching teams competing in regular competition matches that are typically played weekly. The recovery time between matches in a tournament is often inadequate, and fatigue may be accumulated over successive matches, impacting upon individual and team performance. This study quantified the movement demands and match activities of futsal players during a tournament, with a view to examining differences in movement demands and ball possession throughout the tournament. **Methods** One team from New South Wales (NSW) competing in the Open men's division at the Australian National Futsal Championships participated in this study. Matches were played over 3 consecutive days. There was a minimum of 3 hours between matches involving the same team. The team analysed for this study played 1 game on day 1, 3 games on day 2 and 2 games on day 3, with a total of 6 matches contested. For each match assessed, movement demands, match activities and ball possession were monitored by video analysis. **Results** Relative to total match time, the NSW team decreased their ball possession from 32.7% in match 1 to 21.0% in match 5 ( $p=0.02$ ), and increased the duration of the ball out of play from 36.8% in match 1 to 49.2% in match 5 ( $p<0.01$ ). There was a 55.3% increase in the average relative match distance walking from match 1 to 5 ( $p=0.05$ ), and a 38.1% decrease in the average relative match distance sprinting from the first half of the tournament (matches 1 – 3) to the second half (matches 4 – 6) ( $p<0.01$ ). Furthermore, there was a 34.1% decrease in the average relative sprinting duration from the first half of the tournament ( $0.85 \pm 0.58\%$ ) to the second half of the tournament ( $0.56 \pm 0.41\%$ ) ( $p=0.04$ ). There were no significant differences for match activities throughout the tournament. **Discussion** The decrease in the ball possession duration indicates that the NSW team may have reduced their ability to control the ball towards the end of the tournament, and may have been forced to deliberately kick the ball into an open area or out of play, in order to take away the opportunities for the opposition to gain control of the ball. This may be directly related to the increase in the duration of the ball out of play from match 1 to match 5. The changes in movement demands observed suggest that the players experienced fatigue towards the end of the tournament as indicated by the decrease in sprinting distance and duration as a result of limited recovery between matches. Coaches can use this information to control the game more effectively whereby players can be rotated before they fatigue, in order to optimise team performance for the duration of the tournament.

## MATCH EVENTS IN FUTSAL: DIFFERENCES BETWEEN RELATIVELY HIGH CALIBRE AND LOW CALIBRE TEAMS

DOGRAMACI, S., WATSFORD, M., MURPHY, A.

UNIVERSITY OF TECHNOLOGY, SYDNEY

**Introduction** Several team sport studies have examined the physiological and match-play differences between teams of different playing levels. However, no previous study has performed an investigation comparing differently skilled teams of the same relative playing level within the same sport. This study aimed to investigate the differences in match demands between sub-elite futsal teams from Australia, Brazil and Spain, as well as detect key performance indicators which differ between the teams. As Brazilian and Spanish futsal match-play is superior to Australian futsal (current world rankings), the outcome of this study may aid the improvement of Australian futsal match performance. **Methods** One futsal team from Australia, Brazil and Spain were used for this study. All teams were at a level of play where players could be scouted to represent their country in futsal, therefore, they were of an equivalent competition standard. Four matches involving the Australian team, four matches for the Brazilian team and five matches for the Spanish team were analysed. For each match, movement demands and match activities such as passing and goal-shooting success were monitored by video analysis, with these activities tracked during the entire match-play with the exceptions of timeouts and half-time periods. **Results** The Brazilian team recorded the greatest possession duration of the ball ( $40.0 \pm 10.4\%$ ) when compared to the Australian and Spanish teams ( $30.9 \pm 2.54\%$  and  $23.5 \pm 2.73\%$ , respectively,  $p<0.05$ ). The Brazilian team also performed the greatest number of successful passes per minute of match-play ( $31.2 \pm 1.06$ ), when compared to the Australian and Spanish teams ( $21.2 \pm 0.60$  and  $23.5 \pm 0.81$ , respectively,  $p<0.05$ ). Additionally, the Australian team performed the greatest number of shots on goal per minute of match-play ( $1.40 \pm 0.07$ ). **Discussion** The greater ball possession percentage of the Brazilian team suggests that they were in greater control of the game when compared to the Australian and Spanish teams. The Brazilian team also made a significantly higher number of successful passes per minute of match-play, followed by the Spanish team and the Australian team. The Australian team produced the highest number of shots on goal per minute of match-play, suggesting a greater determination to score goals rather than retain possession. Australian futsal players and teams may need to focus on motor skill and technical skill training in order to improve ball possession skills and team performance during futsal match-play. Further, Australian futsal players should have more patience when in control of the ball, rather than taking risks in passing and kicking which may result in losing possession or a goal being conceded.

## ALTERATION OF PLAYING PATTERN IN MALE OLYMPIC HANDBALL

SKARBALIUS, A.

LITHUANIAN ACADEMY OF PHYSICAL EDUCATION

**Introduction** Notational analysts have focused on general match indicators (technical and tactical demands) in team sports (Hughes, Barlett, 2006). Statistics, presented in official documents of the International Handball Federation, enable to make further deep analysis of sport performance in olympic male handball (Skarbalis, 2002). The aim of the research was to carry out the tendencies of playing pattern of male olympic handball through 4th decades: from Munich (1972) Olympic Games (MOG) to the Beijing (2008) Olympic Games (BOG). **Methods** Statistics of matches ( $N = 388$ ) played by national teams in 10th Olympics were taken from the official statistics documents of the International Handball Federation. All values were expressed as means  $\pm$  SD. The value of  $P < 0.05$  was accepted as significant. **Results** During 36 years (MOG –  $16.3 \pm 1.9$ ; to BOG –  $27.3 \pm 4.3$ ) teams scored 11 goals more ( $P < 0.001$ ) per match, both teams scored 22.3 ( $P < 0.001$ ) goals more ( $32.3 \pm 7.2$ , and  $54.6 \pm 6.9$  respectively). Winners scored 19.6  $\pm$  3.7 goals in MOG, and 9.5 goals more ( $P < 0.001$ ) in BOG ( $29.1 \pm 3.9$ ). Goals scored by losers increased ( $P < 0.001$ ) by 10.5 goals ( $13.9 \pm 1.8$ , and  $24.4 \pm 4.3$  respectively). Number of attacks increased ( $P < 0.001$ ) by 16.6 attacks ( $39.4 \pm 6.2$ , and  $56.0 \pm 4.4$  respectively), efficacy of attacks increased ( $P < 0.001$ ) by 14.1% ( $34.6 \pm 6.3$ , and  $48.7 \pm 7.4$ ). Shots efficacy increased ( $P < 0.001$ ) by 15% ( $40.3 \pm 5.3$ , and  $55.3 \pm 9$  respectively), but goalkeepers efficiency decreased ( $P < 0.001$ ) by 8.5% ( $43.8 \pm 6.9$ , and  $30.0 \pm 8.0$  respectively). **Discussion** The difference between scored and missed goals through fourth decades decreased by 1 goal. This allows to assert of increasing equitable performance by rival teams in elite male handball. Increasing a number of attacks, efficacy of attacks, and efficacy of shots might be characterise as the dominant features of players individual skills in offense as in defense (Skarbalis, 2002, 2010). Decreasing ratio (4.8%) of positional attacks and increasing ratio of counterattacks as well as efficacy of latter index might be thought as increasing dynamics of the game (Skarbalis, 2002, 2010). The

phenomenon of modern olympic male handball is that winners play more vigorous and aggressive, and make more violations (2 minutes suspension increased [ $P < 0.001$ ] in duoble: from  $3.3 \pm 1.6$  to  $7.1 \pm 3.2$ ). In conclusion: modern olympic male handball is more dynamic; winners play more active and aggressive handball; prevails individual actions in offence; elite rival teams are the same performance level; complex indicators of sport performance might decide the end of a match. ## A COMPARISON OF PLAYER AND COACH IMPRESSION OF TRAINING LOAD OVER THE SOCCER SEASON

JANSE DE JONGE, X.1, DAVIES, S.J.G.1, CLARK, A.C.1,2

1 UNIVERSITY OF NEWCASTLE, AUSTRALIA; 2 CENTRAL COAST MARINERS FOOTBALL CLUB, AUSTRALIA

To optimise performance it is important to monitor training load to ensure that the planned load is executed by athletes. Especially in team sports objective player monitoring through heart rate and time-motion analysis may be out of reach due to its cost limitations. The use of session Rating of Perceived Exertion (RPE) has proven useful for monitoring players' internal training load. When no direct player monitoring options are used, many coaches will rely on their own impression of executed training load. This study investigated the relationship between the planned training load, the coaches' perceptions of executed load and the team's session RPE load. The potential differences in perception throughout the soccer season were also addressed. Sixteen male elite soccer players (age  $25 \pm 4$  yrs, height  $1.83 \pm 0.05$  m, weight  $82.2 \pm 7.5$  kg) were monitored over 30 training sessions, consisting of 15 pre-season and 15 in-season sessions. Training load was matched so there was no significant difference in planned load between pre-season and in-season. Upon completion of each training, players' session RPE (10 point scale) was recorded and each of the three coaches was individually asked for their impression of executed load on the same RPE scale. Team load was calculated as player's mean session RPE x session duration (min), and coaches' load as coaches' mean impression of load x duration. Before each session players were asked to rate their stress, fatigue, soreness and training enjoyment on a 5 point scale (1 very bad to 5 very good). Over all sessions there was a strong correlation between coaches' load and both planned load ( $r=0.90$ ) and team load ( $r=0.91$ ). When split into season phases the correlation between coaches' load and team load dropped from 0.96 pre-season to 0.83 in-season. This coincided with a significant drop in the difference between coaches' load and team load from pre-season ( $36 \pm 52$ ) to in-season ( $-17 \pm 72$ ). Player ratings indicated no difference over the season for stress and soreness, while both fatigue and training enjoyment were significantly greater in pre-season. These findings indicate that coaches tend to overestimate training load in pre-season, while underestimating training load in-season. It may be expected that players are more fatigued in-season and therefore report a higher session RPE, which may be un-observed by coaches. However, this assumption is contradicted by the finding of a greater fatigue rating in the pre-season. The players did report a decrease in training enjoyment in-season, which may reflect staleness. This may account for the players' higher perceived training load in season and the concurrent under-estimation of coaches' load.

## TEACHING DANCE TO CHILDREN: SHOULD IT CONTINUE TO BE DONE KINAESTHETICALLY?

CUNLIFFE, D., STOPFORTH, M., RIST, R.

SOUTHAMPTON SOLENT UNIVERSITY

TEACHING DANCE TO CHILDREN: SHOULD IT CONTINUE TO BE DONE KINAESTHETICALLY? Cunliffe, D.1, Stopforth, M.2, Rist, R.3 1: SSU (Southampton, UK), 2: SSU (Southampton, UK), 3: TPSPA (Tring, UK) Introduction The art, or skill, of teaching often breaks down at the point of transferring the information from the teacher to the pupil. Varying methods of teaching dance have been used, such as a Movement-Based approach (Marx, 2009): Student-Centred Approach (McCarthy-Brown 2009) and Kinaesthesia method (Geber & Wilson, 2010), yet neither of these authors have addressed the issue of teaching to a child's preferred learning style. The issue of preferred learning styles has been recently addressed (Beadle, 2010; Cunliffe, 2010 and Myers 2010) when in a teaching domain, and as such, dance teachers who only educate through direct movement appear to be failing to maximise the potential of their pupils' 'understanding' of what they are asked to perform. Methods Appropriate ethical clearance was granted from a University's Ethical Committee before permission was sought and granted to assess the preferred learning styles of each pupil across school years 7-13 ( $n=194$ ) from one Music and Dance Excellence (MADE) school within the UK. The Learning Styles Questionnaire for Children - LSQ-C was selected as it divides preferred learning styles into three distinct categories, either Visual, Auditory or Kinaesthetic learners over a 30-point questionnaire. To improve reliability, the LSQ-C was administered three times over a six week period to get a mean score for each child. Results The mean scores for each preferred learning style (VAK) for all children across all seven year groups exhibited a difference; Visual (14.23, SD 4.19); Auditory (6.51, SD 2.71); Kinaesthetic (9.26, SD 3.87). When differences in preferred learning styles were analysed using a Oneway ANOVA, the results indicated that there was no significant difference for kinesthetic preference between all seven year groups ( $F=1.425$ ,  $p=0.207$ ). Discussion Whilst these results support the work of dance teachers who educate children through the practical delivery of movements, it must be stressed, that from this pilot study, only using this teaching method could alienate the learning of children who prefer a different mode of learning. Therefore, dance teachers need to ensure they select a differentiated delivery strategy to allow all children to learn together without any disadvantage being placed upon them. Further research will see the project extending to the other eight MADE school within the next year. References Beadle, P. (2010). *How to Teach*, 201-203. Crown House Publishing, Carmarthen. #### IS SOCCER KICKING TECHNIQUE AGE AND GENDER DEPENDENT?

KATIS, A., DALAMITROS, A., KELLIS, E.  
ARISTOTLE UNIVERSITY OF THESSALONIKI

**Introduction** The examination of females and young soccer players kicking performance have not received the appropriate attention (Kellis and Katis, 2007). For this reason, training programs for female and young players are based on experimental data which are appropriate for men. The purpose of the present study was to examine the kinematic differences in soccer kick biomechanics between male, female and young soccer players. **Methods** Ten male (age:  $26.3 \pm 4.9$  yrs), ten female (age:  $24.4 \pm 4.2$  yrs) and ten boys (age:  $15.1 \pm 0.7$  yrs) amateur soccer players performed consecutive instep kicking trials. The kick with the highest ball velocity was further analyzed. Three-dimensional kinematics (6-camera Vicon motion analysis system, 120 Hz) allowed estimation of ball speed, ball-to-foot speed ratio, linear velocities of the ankle, knee and hip during the kick. Ground reaction forces were also recorded using a Bertec force plate. A one-way analysis of variance was used for comparisons between the three examined groups. **Results** Ball velocity was significantly higher ( $P < 0.05$ ) for male ( $21.5 \pm 2.1$  m/sec) compared to female ( $18.4 \pm 1.5$  m/sec) and young players ( $19.4 \pm 1.7$  m/sec). In contrast, foot/ball ratio (1.60, 1.44 and 1.58 for male, female and young players, respectively) and joint linear velocities did not differ ( $P > 0.05$ ), with the exception of the linear velocity of the ankle at ball impact, being significantly higher ( $P < 0.05$ ) in male ( $13.3 \pm 1.6$  m/sec) compared to female ( $10.8 \pm 0.8$  m/sec) and young players ( $11.1 \pm 0.7$  m/sec). Vertical and mediolateral ground reaction forces were significantly higher ( $P < 0.05$ ) for young players ( $2.6 \pm 0.6$  BW and  $0.8 \pm 0.2$  BW) compared to male ( $1.8 \pm 0.4$  BW and  $0.4 \pm 0.1$  BW) and female players ( $2.3 \pm 0.3$  BW and  $0.5 \pm 0.2$  BW for vertical and mediolateral GRFs, respectively). **Discussion** Previous studies underline the importance of the muscle mass (Manolopoulos et al., 2006) and the velocity of the distal segments (Asai et al., 2002) for better performance. The present study indicated that the kicking performance of male players is higher compared to female and young players, probably due to higher levels of muscle mass and higher ankle velocity of the ankle at ball impact. However, the kicking pattern was similar among the three examined groups indicating that soccer kick is a well-practiced skill with similar joint and segment movements. **References** Asai T., Carre M., Akatsuka T. & Haake S. #### MUSCLE COORDINATION IN AN OUTDOOR CYCLING TIME TRIAL

BLAKE, O.M., WAKELING, J.M.  
SIMON FRASER UNIVERSITY

**MUSCLE COORDINATION IN AN OUTDOOR CYCLING TIME TRIAL** Blake, OM., Wakeling, JM. *Biomedical Physiology and Kinesiology*, Simon Fraser University, Canada **INTRODUCTION** Muscle activity in cycling has primarily been studied in the laboratory. The activity underlying muscle coordination is dependent on cadence, workload, body position, fatigue, shoe and pedal interface and training status (Hug et al., 2009). However, it is important to conduct research in a natural setting as conclusions from laboratory studies are limited by the ability to recreate realistic environmental conditions. The purpose of this study was to determine the coordination patterns in an outdoor time trial and investigate their relationships to power output (IPO), total muscle activity (Itot), cadence and slope. **METHODS** Six competitive male cyclists cycled 4 laps of 5km on paved roads in the shortest time possible. Muscle activity of 10 leg muscles was measured using surface electromyography (EMG) while PO, cadence, heart rate and slope were recorded. The time-varying intensity of the EMG (Iemg) was calculated (von Tscharnner, 2000) and the dominant coordination patterns were identified using principal components (PC) analysis (Wakeling et al., 2009). Coefficients for muscle coordination were statistically compared to the Itot, PO, cadence, velocity, heart rate and slope. **RESULTS AND DISCUSSION** The first PC (IPC1) highlighted vastus lateralis (VL) and rectus femoris (RF) Iemg. IPC2 differentiated between Iemg in the VL and RF and Iemg in the rest of the muscles. IPC3 uncoupled the VL and RF with more VL in lap 1 and more RF in laps 3 and 4. There was a significant relationship of RF and VL to PO similar to Bini et al. (2008) and both PO and VL Iemg followed a reverse J-shaped pacing strategy (Abiss et al., 2008). In support of previous studies, despite different pacing strategies, the Iemg of the VL (Bini et al., 2008) and RF (Duc et al., 2005) followed the same trend as the PO distribution. Decreased VL appears to have been compensated for by increased Sol, a relative shift to more RF and to a lesser extent GM activation. The muscle coordination patterns significantly covaried with the PO, cadence, heart rate and slope. The VL and RF appear to be primary power producers although compensation from other muscles may be crucial to maintaining PO while delaying fatigue. These results show that muscle coordination changes with the altered locomotor demands of outdoor cycling, and highlights the importance of recording these parameters under field conditions. **REFERENCES** 1. #### CHANGES IN THE JOINT TORQUE OF UPPER LIMB IN OVERHAND THROW AT VARIOUS BALL SPEEDS

URATA, T., YAMADA, K., YAMAMOTO, D., ISHIKAWA, M., ITO, A.  
GRADEATE SCHOOL OF OSAKA UNIVERSITY OF HEALTH AND SPORTS SCIENCES

**Introduction** Overhand throw is multi-joint movements and unique in human. Studies on joint torque about adjustment of movements have been reported mainly in lower limb. However, joint torque in upper limb during overhand throwing with increasing ball speed is not investigated. In the various sports, adjustment of ball speed is an important ability. The aim of this study was to examine the regulation of each joint torque of the upper limb to the different ball speed. **Methods** Five males, without specialized training in throwing, threw balls with overhand at five different conditions: 20%, 40%, 60%, 80% and 100% of the maximal ball speed. The motions were recorded using three high-speed video cameras. Three-dimensional coordinate data from maximal shoulder horizontal abduction position to the ball release position were calculated by the DLT method and thereafter were smoothed by fourth-order Butterworth filter. Peak joint torque before ball release and joint torque at ball release for each ball speed in wrist palmar/dorsal flexion, elbow extension/flexion, shoulder internal/external rotation and shoulder horizontal adduction/abduction were calculated. Repeated-measure one-way ANOVA was used to examine differences between ball speed conditions. **Results** The peak joint torque in wrist palmar flexion, elbow extension, shoulder internal rotation and shoulder horizontal adduction before ball release increased with higher ball speed ( $F(1.302, 5.208)=30.458$   $p<0.05$ ,

$F(4.000, 16.000)=11.983$   $p<0.001$ ,  $F(4.000, 16.000)=25.555$   $p<0.001$  and  $F(2.898, 11.591)=64.437$   $p<0.001$ , respectively). The joint torque in elbow flexion, shoulder external rotation and shoulder horizontal adduction at ball release increased with higher ball speed [ $F(4.000, 16.000)=4.937$   $p<0.01$ ,  $F(2.152, 8.609)=7.699$   $p<0.05$  and  $F(1.248, 4.991)=12.724$   $p<0.05$ , respectively]. However, the joint torque in wrist dorsal flexion at ball release didn't change. Discussion In line with the previous study (Miyanishi et al., 1996; Miyanishi et al., 1997), peak joint torque in shoulder internal rotation, elbow extension and wrist palmar flexion contributed to the acceleration of ball speed. In contrast, joint torque at ball release in shoulder external rotation, elbow flexion and wrist dorsal flexion were used to transfer the energy into ball. In summary, these results indicate that "whip-like motion" is performed for the regulation of ball speed. References Miyanishi, T. Fujii, N. Ae, M. Kunugi, Y. Okada, M. (1996). ### STUDY ON THE KNEE ANGLE SIZE EFFECT IN A SUCCESSFUL FIRST TENNIS SERVE

SGRÒ, F., MANGO, P., SCHEMBRI, R., LO PICCOLO, A., LIPOMA, M.

UNIVERSITY OF ENNA

Study on the knee angle size effect in a successful first tennis serve Sgrò,F.,Mango,P.,Schembri,R,Lo Piccolo,A.,Lipoma, M. Physical activities and wellness science Faculty (Enna, Italy) Introduction In last years several definitions have been formulated about the tennis serve. Elliott et al. defined the tennis serve as one of the fundamental strokes during the development of a match (Elliott et al., 1986), while Sakurai et al. described the serve as the most effective shot that can influence the result of the game (Sakurai et al., 2007). The serve is based on bio-mechanics principle of "kinetic chain" but, as reported by Girard (Girard et al, 2007), an important role on the serve effectiveness is covered by the knee motion. In this work we propose a study about the proprioceptive angle size provided by the knee in the first serve produced by tennis players of different performance levels. Methods The twelve athletes involved in the experimental study have the follow characteristics: age:  $22.5 \pm 6.5$  years; height:  $176 \pm 6.7$  cm; body mass:  $70.1 \pm 4.9$  kg. Based on International Tennis Number (ITN) the athletes are grouped in: Novice (N), Intermediate (I) and Elite (E), with ITN respectively 10, 7 and 4 (4 athletes for each group). The experimental scenario is an outdoor clay tennis court, where we have placed 3 sync digital cams, one radar gun and a multimedia station. We analysed by means of a professional software of video analysis, Dartfish®, ten successful serves of each athlete, five for each side of the court which have been chosen according to tennis professional coach indications concerning the maximum speed obtained. Results The analysis of performance has interested the knee angle size ( $\theta$ ), the height of impact (Hi) and the speed of the ball (Sb) experimented for each serve. A statistical approach was used to analyse our data, collected by ITN level group. The results of correlation coefficient (r) for  $\theta$ -Hi,  $\theta$ -Sb and Sb-Hi relations show less positive value for N players than I and E ones; moreover, while the trend of r is the same for right/left-court side in N, it is different for I and E. Conclusion The knee angle plays an important role on the effectiveness of successful serves. The performance levels obtained by statistical analyses are consistent within the three groups. The correlation coefficient values suggest, for the I and E players, a specific study based on the skill of each player. References Sakurai S, Jinji T, Reid M, Cuitenho C, Elliott B.(2007). ### SAFETY IN VIA FERRATA CLIMBING FOR CHILDREN

LEHNER, S., SENNER, V.

TU MÜNCHEN

The goal of the study is the optimization of safety requirements and the development an adequate test method for safety equipment for children mountain routes called klettersteig or via ferrata. Via ferrata climbing has become increasingly popular by families with children, but there is currently no specific safety equipment is available for child use and the existing safety equipment for adults are not secure enough for child use. A modification of the equipment for children is not possible because the only criterion to obtain a safety certification is to fulfill the safety requirements specified in European standard EN 958: 2006 "Mountaineering equipment – Energy absorbing systems for use in klettersteig (via ferrata) climbing", where the experimental test method specifies the use of a falling mass of 80 kg. Therefore a human model including a detailed head-neck region has been developed using the multi-body simulation (MBS) software SIMPACK (SIMPACK, Gilching , Germany). The developed 15 segment parameterized human model is based on the up-to-date anthropometrical database of Size Germany. The detailed head-neck model is based on CT data of vertebrae (T3 to C1), ribs, clavicle, sternum and cranium. Corresponding 3D surface models were created describing the exact bone geometries. Implementation of user routines allows the modulation of force elements describing the material behavior of human soft tissue structures such as ligaments, tendons, and cartilage layers. The visco-elastic behavior of each soft tissue structure was calculated as a function of the geometry, loading velocity and the current strain situation. All force elements were validated by tensile tests. A realistic model of the safety equipment includes the fixation to the wobbling masses and a model of a brake employs stitching which progressively tears in case of a fall, providing a gradual deceleration. Different falling situations were simulated, e.g. in a horizontal or vertical start position of the model. For verification of the simulation results a comparison with experimental studies using crash test dummies was performed. One result of the simulations is the release distance of the brake for child and children. Depending on the start situation of the analyzed fall the difference in the release distance of the brake is 0.2 m for a 14 year old child and 0.8 m for a 50 percentile man.

### FACTORS AFFECTING LATERALITY OF STEP LENGTH DURING SPRINT RUNNING

SUZUKI, M., WATANABE, M.

COLLEGE OF EDUCATION

Introduction In human sprint running, it is considered ideal to run with an equal right and left movement. However, because of the difference between the physical characteristics of the right and left sides of a track and field sports player, laterality of step length occurs during sprint running. The aim of this study was to clarify the factors affecting the laterality of step length during sprint running; the factors that were considered were leg length, muscle strength, jump strength in each leg, and the position of the center of balance. Methods The subjects were 26 university students who belonged to the track and field club. To analyze their sprint motion, they were recorded during a 60-m sprint run with high-speed cameras (210 fps) set up on both sides of the sprint track. Therefore, both legs of the subjects were measured for leg length (tibia and femur), isokinetic muscle strength, and jump strength, and the position of the subjects' center of bal-

ance while standing was also determined. Results Laterality of step length was observed in 25 subjects. The step length of the right side was  $1.83 \pm 0.15$  m and that of the left was  $1.81 \pm 0.13$  m. However, a significant difference in the step lengths was not found. On the other hand, a significant correlation ( $r = -0.36$ ) was found between the laterality of step length and the tibia length. Discussion It was hypothesized that the laterality of the tibia length influences the running motion. Therefore, the movements of the support leg were analyzed, and parameters such as the change in angle and angular velocity of hips, knees, and ankle joints were measured. Path analysis result indicate that the leg with the longer tibia had a greater knee joint angle at the time of foot contact ( $\beta = 0.44$ ). After the foot contact, the change in the knee angle of the longer leg was large ( $\beta = 0.65$ ). Moreover, the angular change in the extension of the hip joint became small during the foot contact period ( $\beta = -0.44$ ), because of which the step length became short ( $\beta = 0.37$ ). To produce a high sprint speed, there must be an adequate movement of the support leg (Miyashita et al., 1986; Ito et al., 1998). In other words, the better sprinters had a smaller change in the knee angle during contact. In conclusion, the longer leg produces bad motion during contact, because of which the step length becomes shorter. References Ito A, Ichikawa H, Saito M, Sagawa K, Ito M, Kobayashi K. (1998). ## **RUNNING SPEED, JUMPING ABILITY AND THE JUMPED RESULT AMONG UNIVERSITY STUDENTS IN LONG JUMP**

VÁGÓ, B., SZABÓ, E., BENCZENLEITNER, O., SZALMA, L.

*SEMELWEIS UNIVERSITY FACULTY OF PHYSICAL EDUCATION AND SPORT SCIENCES*

**Introduction** The aim of the study to investigate the correlation of running speed, jumping ability and the jumped result among university students in long jump. **Methods** Eighty-two physical education university students (40 women and 42 men) participated in an eight-week/eight-lesson unit on long jumping. During the lessons they participated in traditional learning drills, followed by commonly accepted step by step elongated approach jump attempts, and finally, a 12 stride approach long jump competition. Besides registering their jumping results, a questionnaire was administer in order to find out the subjects' opinion about the relationships between their learning progression and initial motor skills in track and field. **Results** We detected very high correlation among females between 60m and long jump (0,8), but for males correlation was small (0,23). Fifty percent of the subjects indicated that their former sprint experience had the greatest positive inter task transfer on their learning progression. The standing long jump was named as the most important even by 38.9% of subjects. In addition, 63.3% of the subjects appointed jumping ability to be more important than running speed. The majority of the subjects (60.5%) felt the 12 strides as the most effective length for their approach, while others (21.9% and 15.4%) preferred 10 and 8 strides, respectively. **Discussion** It was very interesting not to find a correlation among 60m and long jump results in case of male. The other strange thing, that the majority of the subjects (63.3%) felt the jumping ability to be more important than running speed.

## **ANALYSIS OF THE LONG JUMP TAKE OFF PHASE**

MAMPIERI, L., PIACENTINI, M.F.

*UNIVERSITY OF ROME*

**ANALYSIS OF THE LONG JUMP TAKE OFF PHASE** Mampieri, L.I, Piacentini, M.F.1 **1:Department of human movement and sport sciences (University of Rome-Foro Italico, Italy)** **INTRODUCTION** Run-up and take-off are the two phases that will determine the success in long jump. Results from previous studies showed that take-off execution can discriminate between the best and the worst performance (Chen-Fu and Chen-Shou, 2007). The purpose of the present study was to show that cinematic parameters discriminate among different performance levels with the hypothesis of a better performance achieved with a higher angular joint speed in the propulsive phase and a lower angular joint speed in the braking phase. These two parameters have never been evaluated previously. **METHODS** Five athletes were divided in two groups on the basis of their experience and age: more experienced (group A:  $n = 2$ , age  $20 \pm 1$  years), seven years of previous specific training and less experienced (group B:  $n = 3$ , age  $15.5 \pm 0.92$  years), four years of previous specific training and tested during a training session. At least three jumps were analyzed for each athlete. The following long-jump parameters were obtained by videoanalysis (Dartfish TeamPro): penultimate step length; horizontal and vertical touchdown and take-off velocity; time on board; angular metatarsal speed; braking and propulsive speed of ankle and knee respectively, measured from touchdown to take-off; braking and propulsive duration of ankle and knee respectively; long jump training distance (LJTD). Differences between parameters were analyzed with an unpaired student t test ( $P < 0.05$ ). A Pearson correlation was performed between all parameters and LJTD for both groups ( $P < 0.05$ ). **RESULTS** Significant differences ( $P < 0.05$ ) were observed in LJTD between A ( $6.22 \pm 0.25$  m) and B ( $4.9 \pm 0.57$  m). Significant differences ( $P < 0.05$ ) were observed between groups in long jump parameters: penultimate step length (A:  $2.12 \pm 0.5$  m; B:  $1.96 \pm 0.2$  m); ankle propulsive speed (A:  $1083 \pm 333.3^\circ/\text{s}$ ; B:  $767.6 \pm 282^\circ/\text{s}$ ); knee braking speed (A:  $-405 \pm 92.7^\circ/\text{s}$ ; B:  $-524.7 \pm 124.9^\circ/\text{s}$ ) and knee propulsive speed (A:  $711.4 \pm 110.3^\circ/\text{s}$ ; B:  $550.5 \pm 83.4^\circ/\text{s}$ ). Knee propulsive duration was significantly different between groups (A:  $0.05 \pm 0.01$  s; B:  $0.07 \pm 0.01$  s). Time on board was significantly correlated with performance in A ( $r = -0.58$ ,  $P < 0.05$ ) but not in B. **DISCUSSION** The most important results of the present study demonstrated that angular ankle and knee propulsive speed during take-off were higher in more experienced athletes while time on board and knee braking speed were lower. Differences between groups showed how more experienced athletes tried to perform long jump using run up velocity, a correct last two steps technique and less time in take-off execution. **REFERENCES** Chen-Fu H., Chen-Shou K. (2007) J. Biomech XXI ISB Congress, 2007.

## **THE EFFECT OF SEAT HEIGHT AND CADENCE ON GASTROCNEMIUS MUSCLE LENGTH, ACTIVATION AND CONTRACTION MODE DURING CYCLING**

LI, F.X., CONNICK, M.

*UNIVERSITY OF BIRMINGHAM*

**Introduction** Research suggests that large variations in seat height and cadence are detrimental to cycling economy (e.g. Lucia et al., 2004). The optimal seat height and cadence range is likely to be narrow with studies typically finding optimal values between 96-100% of trochanter height (TH) for seat height and 90rpm for cadence suggesting that specific knee and ankle angles are important for optimal cycling biomechanics (Rankin and Neptune, 2010). The gastrocnemius muscle length is influenced by the ankle and knee joints and transmits muscle forces to the pedal (Raasch et al., 1997). Changes in cadence and seat height influence the length and activation of the gastrocnemius which could affect its function and cycling economy (Sanderson et al., 2009). Gastrocnemius contraction mode during late propulsion (eccentric vs. concentric) has also been shown to change with cadence but has not been shown to change with seat height (Gregor et al., 1991). Eccentric contractions of gastrocnemius could be evidence of slowing the rate of knee extension during propulsion

(Roberts and Azizi, 2010). This study aimed to determine if narrow ranges of cycling cadence and seat height influence oxygen cost, gastrocnemius length, activation, contraction mode and peak knee extension velocity. Methods Ten cyclists performed nine 5 minute cycling bouts at 200Watts which comprised 3 cadences (75, 90 & 100rpm) and 3 seat heights (100, 98 & 96%TH). 3D kinematics of the right lower limb and EMG from gastrocnemius were recorded for 30 seconds. Muscle length was calculated using ankle and knee position. Results VO<sub>2</sub>, gastrocnemius activation, gastrocnemius eccentric contraction and peak knee extension velocity significantly increased with cadence. The gastrocnemius operated at a shorter length at higher cadences. However, only gastrocnemius eccentric contraction during late propulsion and peak knee extension velocity increased with seat height. Discussion Changes in seat height that do not affect oxygen cost of cycling, gastrocnemius activation or gastrocnemius operating length may still influence cycling biomechanics. Seat height is likely to affect the capacity of the gastrocnemius to transmit forces to the pedal because during late propulsion the gastrocnemius eccentrically contracts possibly to limit knee extension velocity. ## THE ANALYSIS OF X-FACTOR ON GOLF SWING USING TWO DIFFERENT IRON ON AMATEURS GOLFERS

FERNANDES, O., VAZ, J., CASTRO, M., CONSTANTINO, A., CORREIA, N., SILVA, L.

ÉVORA UNIVERSITY

Introduction: During the GS the pelvic and the upper torso rotate about tree anatomical axes. On transverse plane the shoulder rotate against the pelvis to produce a maximum angular displacement between shoulder and hips, normally call as a X-Factor (XF) (McLean, 1997). This movement creates a strongly twisting body to store energy for maximum speed of the club head at impact. The XF beyond physical limits cloud be a main problem on GS. The main purpose of this work is to understand the mechanics of the hip and shoulders during two different club irons (a Pitch and 4-iron) using the changes in the XF. Methods: Three amateurs golfers volunteered to participate in this study. All participants signed an informed consent approved by the Ethical Review Board. The subjects were asked to perform a GS using two different clubs. The pitch shots is use to produce a higher trajectory and the 4-iron is used for longer distances. Subjects were instrumented with 4 reflective spherical markers placed bilaterally at the shoulders (top of the acromion process), and 3 markers defined the pelvis, 2 markers at the anterior superior iliac spines. The golfers hit a minimum of 8 balls for each iron into a hall. We analyzed 3 trials based on the quality of kinematic data. The GS motion was recorded with three Basler (A602fc) camera at 100Hz, And a fourth camera CASIO EX-FH20 of 1000Hz was placed anterior to the ball. The SIMI® Motion 3D software was use to tracking process. We analyze the shoulder and the hip displacement on transverse plane of two vectors; the shoulder vector connecting the shoulder joint centers and the hip vector connecting the anterior and superior iliac spherical markers. The planar angle between these two vectors was measure and compared. To minimize differences between golfers we only compared the angle position in five moments of the GS at (sBS) – start of back swing; (sFS) -start of forward Swing; (hFS) – horizontal position of the club in forward Swing; (iB) - ball impact, and (hFT) – horizontal position of the iron at follow-through. Statistics T-test methods were use to compare the difference between Results: The results of the statistical analysis revealed no significant differences on the angular position of the shoulders and hips using different irons, as well as no differences on the X-F in different instant phases of GS. Discussion: All golfers showed different way to perform the GS according to rhythm and velocity of the motion, but in those particular instants the position of the club maintain also most the same, show some concerned about the technique during the motion. Conclusion: We conclude that the amateur golfers do not change the technique of the GS, which indicates the same mechanic stress even if they use a different iron.

## SOFT TISSUE ARTEFACTS IN THE SHANK DURING THE GOLF SWING

MOLLOY, M.P., HANLON, M., WALLACE, E.

UNIVERSITY OF ULSTER, JORDANSTOWN

Introduction Soft tissue artefact (STA) is widely accepted as a considerable source of error in 3D motion capture (Cappello et al., 1997). Research on the magnitude and nature of STA indicate that the phenomenon is highly task dependent (Stagni et al., 2005). Techniques suggested to minimise STA are largely concerned with gait analysis; little consideration has been given to the influence of STA on the analysis of golf swing performance. This study aimed to assess the extent of STA during the golf swing using two alternative marker sets. Methods Ten male right-handed golfers were recruited (mean age 35.1yrs, SD 15.3; mean handicap 11.9, SD 6.1). Exclusion criteria included pathology that impacted golfing performance. A comparison was made between knee joint kinematics using a standard, lower-body six degree of freedom (6DoF) marker set and a 6DoF marker set including an alternative shank cluster. The alternative shank cluster was designed according to guidelines proposed by Cappozzo et al. (1997); it attaches to the anterior aspect of the distal tibia where STA potential is considered to be lowest. Single markers attached to the tibial tuberosity, distal tibia, lateral and medial malleoli provide a reference set of markers with minimal inter-marker movement (Peters et al., 2009). Participants took ten shots with a driver for each of the marker sets. Shot consistency was verified using a Trackman system. Left and right knee angle in the X, Y and Z planes were identified at mid back-swing, mid down-swing and ball impact. Mean error values between reference markers and clusters were calculated and compared using a paired t-test (alpha level of  $p < 0.05$ ). Results Left knee angle showed no significant differences ( $p > 0.05$ ) in errors between clusters for any of the swing phases. Significant differences were evident in the right knee in the sagittal plane (X) at mid back-swing and the coronal plane (Y) at mid down-swing and ball impact. Mean errors were 0.55, 1.15 and 1.48 degrees respectively. Mean errors were smaller in the marker set incorporating the alternative cluster. Discussion The lack of significant differences between the clusters on the lead (left) leg provides some reassurance that a traditional 6DoF marker set provides comparable positional data to an optimised tibial marker set. Measurement of the trailing knee, where there is greater axial rotation and flexion, may improve with a modified cluster. References Cappello A, Cappozzo A, La Palombara PF, Lucchetti L, Leardini A. ## EFFECTS OF NON-CUSTOM MOUTHGUARDS ON MUSCULAR STRENGTH AND VERTICAL JUMP HEIGHT IN COLLEGIATE ATHLETES

EGRET, C.

BARRY UNIVERSITY

EFFECTS OF NON-CUSTOM MOUTHGUARDS ON MUSCULAR STRENGTH AND VERTICAL JUMP HEIGHT IN COLLEGIATE ATHLETES Egret, C. 1, AbdelFattah, M. 2, Ludwig, K. 1 1: Barry (Miami, USA) 2: UF (Gainesville, USA) Introduction A complex relationship exists between the joint of the jaw and the muscles of the head and neck, as well as the entire body (Knapik et al., 2007). Therefore, appliances that reposition the mandible may help reduce stress and tension in the muscles, improve abnormalities in body posture, and increase physiological and exercise performance. Most of the literature is focused on fitted oral appliances for muscular strength performance. Therefore, the purpose of this investigation was to examine the effects of a non-custom mouthguard on knee flexion and extension strength, shoulder external and internal rotation strength, and the effects of such mouthguards on vertical jump height. Methods 24 collegiate varsity-level student-athletes volunteered to participate. The subjects were divided into two groups; one using an upper mouthguard, and the second with a double mouthguard compared to no appliance. Muscular strength was measured in a stabilized chair of a Biodex System 3 dynamometer (Drouin et al., 2004). Jump height was assessed using a Vertec jump height apparatus (Hutchinson et al. 2009). Repetitions of knee flexion/extension and shoulder external rotation/internal rotation at 60 °/s and 180 °/s were taken, as well as jump height differentials. ANOVAs were calculated to examine the effects of group and test (with/without mouthguard) on each measured variable. Results Knee extensor torque at 60°/s and total work at 180°/s were significantly higher with both appliances. No differences were found for the shoulder joint. Jump height was improved but not significantly. Discussion The shoulder was unaffected by the appliances, while the knee was slightly improved. A reason may be related to the type of joint. The knee is a more stable, weight-bearing joint, while the shoulder has much less restriction and is not weight-bearing. The stability and structure of the knee may contribute to a stronger "pulley" in the kinetic chain in terms of the effect of placing a mouthpiece in the oral cavity. This improvement may impact some athletes, especially those to which knee extension is often performed (i.e., rowing, and any sport that involves running). Future research should investigate the effects of mandibular adjustment on the different joints of the body, as well as utilize varying sizes of mouthguards while still maintaining the non-custom aspect of the appliances. ### PP-BN17 Biomechanics: Muscle Properties

#### EVALUATION OF THE LOWER-LEG MUSCLE CHARACTERISTICS IN ATHLETES WITH COMPLETE SPINAL CORD INJURY

ISHII, Y.1, YAMASAKI, M.2, FUNASE, K.2, UEDA, T.1

HIROSHIMA UNIVERSITY

Methods Eight male subjects with complete spinal cord injury participated in this study (average age; 43.3±14.5 years old). The spinal cord injury level was Th2-3 (1 subjects), Th6 (1), Th9 (1), Th10; (1), Th 11 (1), Th12 (2), L1 (1). The average period after injury was 15 years and 8 months. The sports activities with the wheelchair were marathon, tennis, basket and dance. The average frequency of sports activities was 3.9 days a week (1.7 hours / day). The total muscle area in fascia was assessed by MRI (thigh and leg level) and muscle activity was evaluated by electromyography. Results Circumferences of thigh (COT) for more than 20 years after injury incident were 40.0±2.0cm (right) 40.0±2.6cm (left) and COTs for less than ten years were 32.0±0.0cm (right) and 31.0±1.4cm (left). The areas of quadriceps muscle for more than 20 years were 23.2±0.2m<sup>2</sup> (right) and 11.3±0.8 cm<sup>2</sup> (left) and COTs for less than ten years were 23.4±1.9cm cm<sup>2</sup> (right) and 11.2±0.4cm<sup>2</sup> (left). The three subjects (12 yrs and 7 mos, 26 yrs and 2 mos, 31 yrs and 5 mos after injury) were aware of subjective muscle spasms by sports activity. M spike by electromyography were found in all three subjects. However, M spike and muscle spasms could not found in other subjects. Fatty degeneration of muscles in the lower-limb was occurred with the number of years after complete spinal cord injury, even though athletes continued daily sports activities. Discussion The area of quadriceps muscle and COT were not changed after 20 years of injury in athletes with complete spinal cord injury, despite of fatty degeneration of muscles. The muscle activity by electromyography was found even in the degenerated muscles with subjective muscle spasms. Our study suggested that degenerated muscles of the lower-leg muscle in athletes with complete spinal cord injury may retain muscle activity.

#### EFFECT OF SADDLE HEIGHT ON OXYGEN CONSUMPTION AND EMG OF LOWER LIMB MUSCLES DURING SUBMAXIMAL CYCLING ON A FREE-ROLLER IN CYCLISTS

MURADE, S.

JUNTENDO UNIVERSITY

Effect of saddle height on oxygen consumption and EMG of lower limb muscles during submaximal cycling on a free-roller in cyclists Shinichiro Murade<sup>1</sup>, Akihiro Sakamoto<sup>2</sup>, Ryo Kakigi<sup>1</sup>, Shizuo Katamoto<sup>1</sup> 1 Graduate School of Health and Sports Science, Juntendo University 2 Department of Human System Science, Tokyo Institute of Technology Introduction Oxygen consumption (VO<sub>2</sub>) during pedaling exercise on a cycle ergometer has been shown to increase when the saddle height is low or high as compared to the optimal height (Nordeen-Snyder, 1977). However, this change has not been confirmed using an actual road bicycle although the kinetics and kinematics of pedaling may differ between cycle ergometer and actual bicycle. Therefore, this study aimed to investigate the effect of saddle height on VO<sub>2</sub> using an actual road bicycle. Methods Fourteen male competitive cyclists (18-25 yr) performed 4-min submaximal pedaling using their own road bicycles on a free-roller with a selected gear to produce the speed of 31km/h at 60 and 90 rpm (120-150 w). Five saddle heights (95, 97.5, 100, 102.5 and 105 % of preferred saddle height) were randomly assigned for each cadence without informing the subjects of the saddle height condition. During each trial, VO<sub>2</sub> and heart rate (HR) were measured. Surface EMG signals were also recorded unilaterally (the right side) from the gluteus maximus (GM), biceps femoris (BF), gastrocnemius lateral head (GL), vastus lateralis (VL) and tibialis anterior (TA) between 2'50" and 3'00" of each pedaling trial. Results Increased saddle height resulted in an quadratic rise in VO<sub>2</sub> (p < 0.001) and HR (p < 0.01) for both cadences. Unlike the previous finding using cycle ergometer (Nordeen-Snyder, 1977), VO<sub>2</sub> did not show a U-shaped change with varying saddle heights, demonstrating a different cardiorespiratory response between the cycle

ergometer and actual bicycle pedaling. Higher saddle heights resulted in significantly greater integrated EMG (iEMG, mean of 5 cycles) in GM (60 & 90 rpm,  $p < 0.001$ ) and GL (60 rpm,  $p = 0.001$ ), but iEMG of other three muscles (BF, VL, TA) were not influenced by the saddle height changes for both cadences. Discussion The increased iEMG in GM and GL with higher saddle heights may have resulted from a greater effort to generate torque to maintain a given speed due to the effect of angle-torque relationship, and from exaggerated kinetic or kinematic behaviors of the hip and ankle joints. These changes possibly accounted for the observed rise in VO<sub>2</sub> and HR with higher saddle heights. Further EMG analysis as well as mechanical analysis is warranted to uncover the exact mechanisms for the different cardiorespiratory responses between cycle ergometry and actual road bicycle, and among saddle heights. ### CHARACTERISTICS OF MUSCLE ACTIVITY ON LOWER LIMB MUSCLES DURING A PEDALING EXERCISE WITH DIFFERENT LOADS AND PEDALING RATES.

TANAKA, S., KUMAGAWA, D., TSUNODA, N.

KOKUSHIKAN UNIVERSITY

**Introduction** The anaerobic power in cycling ergometer was determined by the load and pedaling rate. Therefore, the anaerobic power generation capacity during pedaling exercise affected size of load and pedaling rates. The previously reports on muscle activity during pedaling exercise, many focused on the lower muscles to work initiative. However, the activity level of each muscles during different load and pedaling rate settings were not cleared. Moreover, in each muscle during pedaling, it has not been cleared that the anaerobic power to the muscle activity is affected by the load and pedaling rate. In this study, the purpose of this study was to investigate characteristics of muscle activity on lower limb muscles during a pedaling with different loads and pedaling rates. **Methods** The subjects were twenty four male collegiate athletes. The anaerobic power generation capacity was measured by a cycling ergometer (Power max V II, Combi co. Japan) with costume made measurement-analysis system. The all subjects performed the exercise for ten seconds with maximal effort intermitted between three-step loads. The loads were 5.0% kp, 7.5% kp and 1.0% kp to body mass. The muscle activities of lower limb were observed by surface electromyography (EMG) methods. The muscle activities were evaluated integrated EMG and % integrated EMG from initial pedaling to peak velocity pedaling. **Results** The integrated EMG during pedaling was not changed due to different loads. The power per integrated EMG ratio in rectus femoris, vastus lateralis, biceps femoris and tibialis anterior muscles were changed by the different loads. However, muscle activity level in initial and peak velocity pedaling were no significant difference among the three trials with the different loads. The biceps femoris and gastrocnemius muscles during peak velocity pedaling were showed higher activity levels than that of initial pedaling. **Discussion** In this study, it were suggested that lower muscles activity pattern depends on the each muscle function. Moreover, muscle activity levels were affected by clank velocity than the load in maximal efforts pedaling. **References** Hug F, Dorel S, (2009). *J. Electromyogr. kinesiol.* 19, 182-198. ### THE INFLUENCES OF WEARING INFRAPATELLAR STRAPS ON EXERCISE PERFORMANCE AND LANDING BIOMECHANICS OF CHILDREN

HSU, T.Y.1, YU, C.Y.1, KUO, W.C.1, LIN, F.L.2, CHANG, C.L.2

1: NATIONAL TAICHUNG UNIVERSITY OF EDUCATION (TAIWAN), 2: GENERAL EDUCATION CENTER, HSIUPING INSTITUTE OF TECHNOLOGY (TAIWAN)

**Introduction** Jumping is a common movement seen in daily exercise for athletes. The ground reaction force, as athletes land on the floor, could be several times higher than their body weight. Hence, athletes' knee joints are easily damaged when they jump repeatedly. One of the common injuries on knee joint is patellar tendinitis. This is an overuse syndrome. An infrapatellar strap is a knee brace especially designed for those who suffered patellar tendinitis, and it is commonly used by athletes. However, exercising with braces limits the effects of knee activeness. Whether or not it affects athletes' performance needs to be further investigated. Therefore, the purpose of this study was to investigate the influences of wearing infrapatellar straps on exercise performance and landing biomechanics of children. **Methods** Twelve sixth-grade children were recruited for this study. The high-speed camera and force platform were used simultaneously for collecting data of kinematics and kinetics. Then, the method for inverse dynamics was applied to calculate the biomechanics parameters of lower limb joints with or without having infrapatellar straps on. In addition, scores of exercise performance were retrieved by means of wearing infrapatellar straps or not. The data was analyzed and tested for its significance via paired-sample t-test ( $\alpha = .05$ ). **Results** The results show that there is no significance in exercise performance. Significance is found, when the participants land, in the shear force of leg knee joints and leg ankle joints, as well as in the max Angular velocity of ankle joints ( $p < .05$ ). **Discussion** Wearing infrapatellar straps does not affect the explosive force, agility, and speed of the lower limb joints. Its influence on kinematics parameters does not benefit the cushion for landing impact, but it tends to decrease the inner force of joints. Specifically, the shear force in knee and ankle joints reaches significance. This may avoid over contraction of the quadriceps, lessens burdens of the patellar tendon, and lowers down the risk of knee joint injuries. **References** Bisseling, R. W., Hof, A. L., Bredeweg, S. ### COMPARISON OF TENDON STIFFNESS MEASURED UNDER ACTIVE AND PASSIVE CONDITIONS

THEIS, N., MOHAGHEGHI, A., KORFF, T.

BRUNEL UNIVERSITY

Muscle and tendon stiffness have been widely studied in exercise and clinical settings. Stiffness plays an important role in locomotion, and the release of mechanical energy. Tendon stiffness is typically calculated by dividing force and elongation of the tendon. For this purpose, participants are commonly asked to perform a voluntary contraction to activate the muscle, and elongate the tendon ("active method"). An alternative method is to record tendon force and elongation from a passive, isokinetic rotation through joint range of motion

("passive method"). Both methods elicit force and elongation from which tendon stiffness can be calculated. The passive method has the advantage of being able to provide estimates of muscle stiffness in addition to tendon stiffness. Further, when employing the active method, the velocity at which the tendon elongates (which has previously been shown to affect tendon stiffness *in vitro*) is less controlled compared to the constant angular velocity of the passive method. Given that both methods have been previously used to obtain tendon stiffness, it is important to understand whether they are in agreement. Therefore, the purpose of this study was to compare tendon stiffness obtained from both the passive and the active methods. A secondary purpose was to quantify tendon stiffness across different tendon elongation velocities. Ten healthy adults (age  $25 \pm 4.6$  y) volunteered to participate in the study. They began by completing a series of maximum isometric plantarflexions, where they were instructed to use a range of contraction velocities. Following these, a series of passive ankle rotations were performed at varying speeds (1, 10, 30 deg•s<sup>-1</sup>) through the ankle's range of motion. Tendon force and elongation were obtained from a combination of motion analysis, dynamometry and ultrasonography. Achilles tendon stiffness for both methods was calculated as the slope of the force-elongation curve. The force range and the velocity of tendon elongation were standardised across the two methods. Stiffness for both methods was calculated at tendon elongation velocities of 1, 4, and 8 mm•s<sup>-1</sup>. We found strong positive correlation *s* between tendon stiffness obtained from both methods at all elongation velocities ( $r = 0.97$  for 8 mm•s<sup>-1</sup>;  $r = 0.95$  for 1 •s<sup>-1</sup> & 4 •s<sup>-1</sup>), and stiffness increased as tendon elongation velocity increased. For both methods, the relationship between these variables was linear (mean  $r = 0.98 \pm 0.02$  and  $0.96 \pm 0.04$  for active and passive methods, respectively). These findings demonstrate good agreement between tendon stiffness obtained from both passive and active methods as long as the range of tendon force and the velocity of elongation are accounted for. However, tendon stiffness is strongly affected by elongation velocity, so caution should be taken when comparing results from the literature, as the velocity of tendon force is not always standardised.

## MUSCLE STRUCTURE AND ACTIVITY OF LOWER LIMBS DUE TO THE ANAEROBIC POWER GENERATION IN UNIVERSITY RUGBY PLAYERS.

YUTARO, K.

KOKUSHIKAN UNIVERSITY

**Introduction** The purpose of this study was to examine that effect of muscle structure and activity of lower limbs muscles due to anaerobic power generation on positional difference in university rugby players. **Methods** The subjects were 30 forward players (FWG) and 31 backs players (BKG) in university rugby players. The muscle volume and a muscle thickness were measured by the body impedance analysis method and B-mode ultrasonic method, respectively. The anaerobic power generation obtained by cycling ergometer with analyzed program. Subjects performed ten seconds with the maximal efforts intermitted of three steps load. The muscle activities of pedaling with different loads were observed by surface electromyography method. In addition, the ratios of anaerobic power to muscle activities were calculated (Power/iEMG ratio) in all the subjects. **Results** FWG were indicated significantly higher than BKG in whole muscle volume (WMV), lower limbs muscle volume (LMV) and WMV/LMV. Moreover, LMV/WMV was not significant difference among the position. However, muscle thickness/WMV was obtained that FWG were indicated significantly higher than that of BKG in thigh anterior and thigh lateral. Time to peak power was obtained significant difference between FWG and BKG in the pedaling. Power/iEMG ratio in FWG was showed higher value than that of BKG in all the pedaling. **Discussion** From these results, it was clarified that anaerobic power generation characteristic were differed by positional difference in university rugby players. And also, FWG showed high power than BKG in less muscle activity during the pedaling. Whereas, it was suggested that FWG was better than BKG at efficiency of the movement. **References** Brewer J, Davis J, Keur J.(1994). ## TIME KINETICS OF ACUTE CHANGES IN MUSCLE ARCHITECTURE IN RESPONSE TO RESISTANCE EXERCISE

CSAPO, R., ALEGRE, L.M., BARON, R.

UNIVERSITY OF VIENNA

**Introduction** The mechanisms responsible for changes in the arrangement of fascicles within skeletal muscles (i.e. the muscle architecture) observed after prolonged periods of physical training are well understood (s. review by Blazevich, 2006). By contrast, few studies have documented the short-term effects of acute bouts of exercise (Kubo et al., 2001; Ishikawa et al., 2006; Brancaccio et al., 2008). The inconsistent results reported in these studies indicate that acute changes in muscle architecture are specific to the muscle examined and the exercise performed and may reflect distinct physiological mechanisms. Closer scrutiny of acute changes in muscle architecture might allow for insights into these mechanisms and provide a rationale for long-term training adaptations. The study aimed to assess acute changes in muscle architecture and its recovery after exhaustive exercise. We hypothesised that repetitive leg press exercise would decrease vastus lateralis fascicle length (Lf), while increasing both muscle thickness (MT) and pennation angles ( $\theta$ ). By investigating the time kinetics of recovery of these parameters, we wished to gain insight into the mechanisms responsible for muscle architectural changes during exercise. **Methods** Vastus lateralis MT,  $\theta$  and Lf were measured in 41 male volunteers ( $25.2 \pm 3.7$  yrs;  $178 \pm 6$  cm;  $76.4 \pm 11.7$  kg) by ultrasonography. Scans were taken at rest as well as 1, 5, 10, 15 and 30 minutes after induction of fatigue by an exhaustive series of single leg press repetitions. **Results** Following leg press exercise MT and  $\theta$  were increased by approximately 7 and 10%, whereas Lf decreased by 2%. Different recovery times (MT: 30 min;  $\theta$ : 15 min; Lf: 5 min) were observed. The degree of fascicle shortening invoked by the exercise intervention was positively correlated to the Lf baseline value ( $r = 0.41$ ;  $p = 0.039$ ). **Discussion** The differential time courses of recovery suggest that the changes in the parameters of muscle architecture are driven by different exercise-related stimuli. While the increases in MT may be explained by augmented muscle perfusion, tendon creep may account for the fascicle shortening and the increases in  $\theta$  observed. The correlation between the degree of fascicle shortening and the Lf baseline value suggests that longer fascicles shorten relatively more in response to leg press exercise. Future research should directly relate the time course of changes in tendon stiffness and muscle perfusion to acute changes in muscle architecture. **References** Blazevich (2006). *Sports Med*, 36(12), 1003-17. ## MUSCLE SHAPE AND DISTRIBUTION OF MUSCLE VOLUME WITHIN THE TRICEPS SURAE MUSCLE GROUP IS INDEPENDENT ON MUSCLE SIZE

ALBRACHT, K., ARAMPATZIS, A.

GERMAN SPORT UNIVERSITY COLOGNE; HUMBOLDT UNIVERSITY BERLIN

The assessment of muscle volume is essential, when evaluating muscle-tendon unit performance. Muscle volume affects directly the maximum mechanical power that can be generated by a muscle. Furthermore, muscles with a smaller ratio of muscle volume to physiological cross-sectional area generate a given force more economical than a muscle with a higher ratio [2]. However, direct measurement of muscle volume is laborious. In general, muscle volume is a fraction of the product of the maximum anatomical cross-sectional area (ACSA) and muscle length (lm). The size of the fraction (shape factor) depends on muscle shape. It was recently shown for the three triceps surae (TS) muscles that the shape factor showed a low inter-subject variability and that an approximation of muscle volume based on this theoretical consideration was possible with an accuracy of 4 to 7% for people who are exposed to normal daily activities [1]. The aim of the present study was to investigate, whether the shape factor and therefore the possibility to approximate muscle volume from ACSAmax and lm is affected by muscle size. According to their muscle activation level 32 subjects were divided into a low (LA), moderate (MA) and high (HA) activation group. The LA group consisted of 13 subjects that were at least active in recreational sports, the MA group consisted of nine endurance runners (training volume of  $14 \pm 4$  hours/week), the HA group consisted of ten elite track & field athletes (sprint, long jump, triple jump) with an average training volume of  $18 \pm 3$  hours/week. Transversal MR Images were acquired from the calf of the dominant leg. Each muscle was reconstructed to determine muscle volume, lm, ACSAmax, the shape factor and the relative contribution of each muscle to the entire TS muscle volume. The HA group had significant ( $p < 0.05$ ) longer muscles, a greater ACSAmax and a greater muscle volume in comparison to the other groups. The scaling factor and the relative contribution of each muscle to the entire TS muscle volume showed significant ( $p < 0.05$ ) differences across the three muscles but no significant ( $p > 0.05$ ) differences across the three groups. In addition, the coefficient of variance for the scaling factor was similar across the groups (LA 4.3 - 6.7%, MA 4.3 - 7.4%, HA 4.3 - 6.7%). Thus, despite considerable differences in muscle size (length, thickness, volume) the shape factor and the relative contribution of each muscle to the entire TS muscle volume is not affected. The fact, that the shape factor is specific for each muscle but similar across the groups indicates that the shape of each muscle is similar within the population and thus independent of muscle size. Therefore, the theoretical consideration can be used to approximate muscle volume from ACSAmax and lm, which are both easily accessible in comparison to a muscle reconstruction. ## THE EFFECT OF A 6-WEEK STATIC STRETCHING TRAINING ON THE MUSCLE AND TENDON PART OF THE M. GASTROCNEMIUS MEDIALIS

TILP, M., RASSINGER, R.

UNIVERSITY GRAZ

THE EFFECT OF A 6-WEEK STATIC STRETCHING TRAINING ON THE MUSCLE AND TENDON PART OF THE M. GASTROCNEMIUS MEDIALIS Tilp, M., Rassinger, R. Institute of Sports Sciences, Karl-Franzens-University Graz Introduction There are only few studies which separated the effect of stretching on the different parts of the muscle tendon unit which are the muscle belly and the tendon. While Morse et al. (2008) reported an increase in muscle elongation but not in tendon, Kato et al. (2010) reported increased tendon elongation but unchanged muscle elongation at an identical passive torque immediately following static stretching. Following a 6-week stretching program Kato (2009) also reported increased tendon but unchanged muscles lengths. Due to the different reports on acute effects on stretching and limited amount of research on long term effects we decided to repeat the approach from Kato (2009). Methods Twelve subjects agreed to participate in the study. Seven subjects performed a static stretching training which consisted of 3x1 min static stretching of the calf muscles for each leg. Five subjects were in a control group and did not perform any stretching training. Before and following the six weeks the ankle joint was moved passively over the greatest part of the range of motion ( $\pm 27^\circ$ ) on a dynamometer. Simultaneously, we followed the motion of the muscle tendon junction with ultrasound B-mode from which we calculated the elongation of the muscle and tendon part of the muscle (Kato, 2009). Mean values of maximum passive torque, muscle and tendon elongation before and following the six weeks were compared with paired t-tests. Results The results from two male subjects in the stretching group had to be excluded due to irregularities in the training period. Muscle length changes increased from  $24 \pm 1.4$  to  $29.4 \pm 5.3$  mm and tendon length changes decreased from  $19.4 \pm 1.6$  to  $14.2 \pm 2.1$  mm during passive stretches significantly. Furthermore, there was a tendency ( $p = 0.07$ ) for decreased peak passive torque ( $29.2 \pm 4.6$  to  $26.0 \pm 2.7$  Nm) in the intervention group. However, significance was not reached due to the small amount of subjects ( $n = 5$ ). Values in the control group did not change. Discussion We conclude that static stretching for 6 weeks affects the elasticity of the proximal, muscle part of the gastrocnemius. This supports findings by Morse et al. (2008) and opposes results from Kato et al. (2010) on acute effects and long term effects (Kato, 2009). However, due to the small intervention group we did not reach significant results for changes in passive torque. We suggest further analysis of the effect of stretching on structural parameters like muscle and tendon stiffness, muscle fascicle lengths and pennation angles. References Kato E. ## TRUNK MUSCULAR RESPONSE DURING 'BRIDGE' STABILIZATION EXERCISES WITH AND WITHOUT LIMB MOTION

VERA-GARCIA, F.J., GARCÍA-VAQUERO, M.P., BROTONS-GIL, E., PECO-GONZÁLEZ, N.

MIGUEL HERNANDEZ UNIVERSITY OF EL CHE.

Introduction Bridge exercises, consisting in stabilizing the trunk with a neutral spine in different positions, are usually performed to develop trunk muscle coactivation patterns to improve spine stabilization (McGill and Karpowicz, 2009). The purpose of this study was to analyse the trunk muscle coactivation patterns during bridge exercises with and without limb motion. Methods Twenty-nine healthy subjects volunteered to take part in this study. Surface electromyography (EMG) was bilaterally recorded from rectus abdominis (RA), external and internal oblique (EO and IO), and erector spinae (ES) while performing isometric bridge exercises: back bridge, back bridge with right leg up, side bridge on right elbow, side bridge on right elbow with left hip flexion (left leg forward), frontal bridge, and frontal bridge with right leg up. EMG signals were rectified, averaged, and normalized to maximal voluntary isometric contraction (% MVC). Results When the stabilization exercises were performed without limb motion, back, frontal and side bridges mainly activated the ES (about 17% MVC), the RA (about 30% MVC) and the right side muscles (mostly obliques), respectively. Limb motion produced significant increase in the trunk EMG. This was especially true for the IO, which generated higher mean activation levels for side bridge with hip

flexion (32.7% MVC), frontal bridge with leg up (28.3% MVC), and back bridge with leg up (21.4% MVC). Comparing between exercises, the highest RA activation was found during the frontal bridge. For the right EO, IO and ES the right side bridge with hip flexion produced the highest activation levels. In addition, for the left EO and IO, the frontal bridge with leg up was the exercise that showed the highest activation. Finally, the highest left ES EMG was found during the back bridge with leg up. Discussion The bridge exercises produced low to moderate mean activation levels. For the lumbar musculature, the highest activation levels were found during back and side bridges. On the contrary, frontal and side bridges showed the highest abdominal activation levels. Compared with conventional exercises, bridges with limb motion resulted in more unstable postures which required an increase in muscle coactivation, possibly to ensure spine stability (Vera-Garcia et al., 2006). In addition, bridges with hip flexion/extension generated twisting pelvis torques that were counterbalanced by increasing twister muscle activation, especially IO. Overall, these results can be used to assist decisions regarding the selection of stabilization exercises. References McGill SM, Karpowicz A. (2009). Arch Phys Med Rehabil, 90, 118-26. ### SOME MECHANISMS OF PISTOL SHOOTING PERFORMANCE

PUKHOV, A., BUCHATSKAYA, I., PIVOVAROVA, E., GORODNICHEV, R.

VELIKIYE LUKI STATE ACADEMY OF PHYSICAL EDUCATION AND SPORTS

Introduction. Successful shooting performance is associated with good postural balance and the pistol stability. The purpose of the present research was to study mechanisms of successful shots. Methods. 8 shooters took part in this research. 60 control shots were made during 105 minutes (exercise PP-3). Telemetric "Qualisis" and "ME 6000" systems were used to record surface EMG and kinematic parameters. The EMG and kinematic data were synchronized and processed by "Qualisis" system. Results. It was revealed that the highest variability of the pistol's position and the changing of the body's position is observed on the Y axis and the lowest – on the Z axis. The variability of movements in the final series of shots did not change considerably in comparison with the initial shots. Successful shooting performance is determined by the stability of all the parts of the shooter's body in the frontal plane (axis Y). EMG amplitude of the most muscles studied increased within the range of 50-60th shots. Discussion. We speculate that a nice shot performance may be considered as the task of minimization of the pistol position change. The arm position seems to be stabilized by the reflex mechanisms: vestibular-spinal and proprioceptive systems, as well as some others.

#### CARBOHYDRATE AND CONCENTRATION ON THE BALANCE BEAM A SOLUTION TO MENTAL AND PHYSICAL FATIGUE.

BATATINHA, H., COSTA, C., CAPERUTO, E.

UNIVERSIDADE PRESBITERIANA MACKENZIE

Introduction: Artistic Gym is a very demanding sport. Training is usually hard and difficult and fatigue is part of the athlete routine. Carbohydrate is one of the most important sources of energy to the body. Its supplementation decreases the symptoms of fatigue providing energy for muscle and mainly for central nervous system (Enoka & Duchateau, 2008) Objective: Our study had the objective investigate the influence of fatigue on performance of the Gymnastics Artistic and the influence of carbohydrate supplementation on the fatigue and performance. Methods: We had 15 female subjects with 12 years divided in two different groups CG(control group) and FG(fatigue group), in two different days. On the first day (Placebo day-PL DAY) CG had a 10 minute warm up, and then five sets of a determined exercise sequence on the balance beam. FG had a 20 minute fatigue circuit then a 10 minute warm up and then the same set of CG. In the second day (Carbohydrate day-CHO DAY) we had the same process, but all subjects ingested a 20% solution maltodextrin before the warm up. We measured blood lactate and glucose on rest, after the warm up and after the sets from CG on both days. From FG we measured also blood glucose and lactate after the fatigue circuit on both days. We used the number of falls as a mental and physical fatigue parameter of the subjects from both groups. Results/discussion: Before the exercise sequence on the PL Day, blood glucose was no different from rest, but on the CHO Day, blood glucose was significant higher for both groups when compared to rest (136,8±13,8 CG before exercise, 94,5±18,0 rest), (118,33±18,85 FG before exercise, 88,0±8,25 rest p<0,05) immediately before the exercise sequence on the balance beam. Lactate fell significantly from before the exercise sequence to the end of the sequence only for the FG on CHO Day (5,23±1,48 before the sequence 3,67±1,16 after the sequence). Glucose and lactate profile showed that the fatigue protocol was intense enough to put the subjects of FG (on both days) in an extreme condition, it also showed that the exercise sequence in the balance beam is not so intense on a physical aspect but has a demanding component in the mental/focus aspect. The number of falls from the exercise sequence on the balance beam was significantly higher from FG compared to CG on PLA Day (3,33±1,37 CG, 5,4 ± 1,14 FG PLA Day). On CHO Day, FG no differ from CG, but comparing PLA Day with CHO Day we observe a reduction on the falls number from CG to CG (3,33±1,37 PLA Day, 1,88±1,13 CHO Day) and from FG to FG (5,40±1,14 PLA Day and 2,29±1,25 CHO Day), evidencing the carbohydrate effect on the performance (physical and mental) aspect. Conclusion: We can conclude that carbohydrate ingestion prior to exercises that are physical and mental demanding, especially in extreme conditions can prevent the deleterious effects of fatigue on performance both on physical and mental aspects. #### EFFECTS OF CARBOHYDRATE AND PROTEIN COINGESTION DURING ENDURANCE EXERCISE ON SUBSEQUENT SAME DAY EXERCISE PERFORMANCE

SHING, C.1, HALL, A.1, LEVERITT, M.2

1. UNIVERSITY OF TASMANIA, AUSTRALIA, 2. GRIFFITH UNIVERSITY, AUSTRALIA

Introduction Muscle glycogen content is related to successful exercise performance and faster replenishment of these stores, that may be influenced by protein modulation of insulin, following an exercise bout will lead to improved recovery and subsequent exercise performance. The aim of this study was to determine the influence of the coingestion of a carbohydrate and protein (CHO + PRO) beverage during an endurance training session on recovery and subsequent same day exercise performance, in comparison to the administration of an isoenergetic carbohydrate beverage. Methods Eight trained, male cyclists (height: 178 +/- 6 cm, body mass: 76.2 +/- 7.7 kg,

VO<sub>2</sub>max: 63±5 ml/kg/min, age: 28±9 years) completed the double-blind, placebo controlled, randomised cross-over trial. Following a 24 hour standardised diet cyclists completed a morning training bout of 2.5 hrs cycling during which they ingested either a CHO + PRO beverage (0.8 g CHO kg<sup>-1</sup> · h<sup>-1</sup> + 0.4g PRO kg<sup>-1</sup> · h<sup>-1</sup>) or an isoenergetic carbohydrate beverage (1.2g CHO kg<sup>-1</sup> · h<sup>-1</sup>) at 250ml every 15 min. Finger-prick blood samples were obtained before the training bout and at 30 min intervals during the training bout to enable the determination of blood glucose and lactate concentrations. Following a four hour recovery period cyclists completed a performance time trial (7kJ/kg). Blood samples were collected pre- and post-training bout and pre- and post-time trial. Differences in the means of biochemical variables were determined with  $p < 0.05$  indicating statistical significance. The uncertainty in the effect was expressed as 95% confidence interval and as likelihoods that the true value of the effect represented substantial benefit or harm (Hopkins, 2002). Results Time trial performance was 2.16% faster with the ingestion of a CHO + PRO beverage (1820s ± 320s, mean ± SD) during the morning training bout, when compared to the ingestion of a carbohydrate only beverage (1864s ± 384s) (77.3% likely to benefit subsequent cycle time trial performance with a 19.1% chance of the effect being trivial and 3.6% chance of the effect being harmful) (44s, ± 72 95% CI). Average blood glucose was significantly lower during the training bout with the ingestion of CHO + PRO (4.11 ± 0.33 mmol/L) when compared to a carbohydrate only beverage (4.94 ± 0.72 mmol/L) ( $p < 0.004$ ). Average blood lactate during the training bout was lower with CHO + PRO ingestion (4.4 ± 1.0 mmol/L; carbohydrate only: 3.7 ± 1.0 mmol/L), although this was not significant ( $p = 0.15$ ). Pre- and post-time trial neutrophil count significantly lower during the CHO + PRO trial ( $p < 0.034$ ). Discussion The co-ingestion of CHO + PRO during an endurance training bout benefited subsequent same day time trial performance. CHO + PRO ingestion during training, as opposed to carbohydrate alone, may enhance recovery. References Hopkins WG (2002). Probabilities of clinical or practical significance. *Sportscience* 6, sportsci.org/jour/0201/wghprob.htm

## THE EFFECTS OF CARBOHYDRATE INGESTION ON THE BADMINTON SERVE FOLLOWING SHORT DURATION FATIGUING EXERCISE

BOTTOMS, L., TAYLOR, K., FEWTRELL, D.

UNIVERSITY OF EAST LONDON

Badminton is an intermittent high intensity sport, which involves both aerobic and anaerobic metabolism (Faude et al., 2007). The serve is an essential part of successful badminton performance. It requires maintenance of high skill levels and is therefore prone to being negatively affected by fatigue developed through match play. The aim of the present study was to determine whether fatigue affected the long and short badminton serve following fatiguing exercise, and whether carbohydrate (CHO) prevented the deterioration in performance. Nine male club standard badminton players (mass 80.9 ± 8.0 kg and age 22 ± 5yr) volunteered for the study. They attended the laboratory on 3 separate occasions. The first visit involved performing an incremental exercise test to exhaustion on the treadmill to determine peak oxygen consumption and peak heart rate (HR<sub>peak</sub>). Following this, they performed two experimental trials in a randomized cross over design separated by a week. The participants were given a CHO electrolyte drink (6.4% CHO) or a matched placebo (PL). The participants performed 10 long and 10 short serves aiming to hit a target, with accuracy being measured pre and post fatiguing exercise. The duration of the fatiguing exercise was 33 minutes (83 ± 10% HR<sub>peak</sub> and 84 ± 8% HR<sub>peak</sub> for the PL and CHO trials respectively). Each cycle consisted of repetitive cycles of 3 minutes of high intensity ghosting, followed by approximately 30s of an adapted Illinois agility test, then 3 minutes of walking at 5km.hr<sup>-1</sup> on a treadmill. Choice reaction time was determined using the Newtest 300 (Oulu Finland) pre and post exercise with the participants sprinting 5m in the direction of the light. Capillary blood samples (20 µl) were taken at rest and post exercise for blood glucose and lactate. CHO and PL were administered after the serving test (500ml) and during the fatiguing exercise (500ml). There was a deterioration in long serve accuracy with fatigue ( $P = 0.002$ ), and CHO ingestion had a tendency to prevent the deterioration ( $P = 0.077$ ). However, there was no effect of fatigue ( $P = 0.402$ ) or CHO ingestion ( $P = 0.109$ ) on the short serve. There was no difference in blood glucose between trials ( $P = 0.851$ ), however blood lactate was greater during the PL trial ( $P = 0.016$ ). Fatigue had no effect on choice reaction time ( $P = 0.162$ ), and therefore CHO had no beneficial effect ( $P = 0.492$ ). These results suggest that only the long serve is influenced by fatigue and CHO had a tendency to prevent the deterioration in performance. ## METABOLIC RESPONSE ON CHO INTAKE DURING MEDIUM INTENSITY EXERCISE TRAINING

BERTIATO, F.

UNIVERSITY OF VERONA

Introduction The present study investigated the effect of ingestion of a 7.5% carbohydrate solution during prolonged sub-maximal exercise on exercise metabolism. Materials & Methods Sixteen subjects cycled for 90 minutes at constant work-load in two different sessions while consuming 200ml of a 7.5% glucose beverage at the beginning and every 15 minutes in one session and a placebo with the same training protocol in the second one. The main measures concern: plasma glucose concentration, inspired oxygen, expired carbon dioxide, respiratory quotient, total energy consumption, oxidation of fats and carbohydrates, heart rate and RPE. Results The energy expenditure was the same with both beverages 6466 (SEM 331.2) KJ with Placebo, 6658 (SEM 340.3) KJ with the sugar solution. Oxidized fats in P were 59.5 (SEM 8.0) g, 51.5 (SEM 7.3) g in CHO ( $P = 0.05$ ) while 265.7 (SEM 21.6) g and 298.0 (SEM 20.9) g carbohydrates were burned respectively in the situation in the CHO and Placebo ( $P = 0.05$ ). The inspired oxygen and carbon dioxide exhaled were similar both as total values AUC O<sub>2</sub> 159.00 (SEM 8.1) l in P, 163.14 (SEM 8.4) l in CHO; AUC CO<sub>2</sub> 142.04 (SEM 7.3) l in P, 148.45 (SEM 7.5) l in CHO and as average change from baseline during the observation time (IAUC O<sub>2</sub> 119.3 (SEM 8.3) l in P, 129.4 (SEM 8.5) l in CHO; IAUC CO<sub>2</sub> 107.6 (SEM 7.7) l in P, 118.7 (SEM 7.9) l in CHO) and as average values during the observation time (T (AUC) O<sub>2</sub> 1.7 (SEM 0.09) l/min. in P, 1.8 (SEM 0.09) l/min. in CHO, T (AUC) CO<sub>2</sub> 1.5 (SEM 0.08) l/min. in P, 1.6 (SEM 0.08) l/min. CHO) for all  $P > 0.01$ . Discussion There are two main observations can be drawn from the results of our experiments: - The consumption of a beverage enriched to 7.5% of CHO helps maintain the value of blood glucose levels higher than baseline during exercise performed after an overnight fast, moderate-intensity (50% VO<sub>2</sub>max) on normal subjects. - The consumption of a beverage enriched to 7.5% of CHO does not change the relative contribution of CHO oxidation and total triglycerides in the same conditions. Drawing conclusions on our study we can say that: taking a drink at 7.5% glucose, which involves taking 90 g/h of carbohydrate during 90 minutes of exercise done at moderate intensity (50% VO<sub>2</sub>max) in 16 normal subjects (13 males and 3 females) mean age 21.88 (SEM 0.77) years and average VO<sub>2</sub>max 3.89 (SEM 0.25) L/min blood glucose rises keeping this parameter constant over the baseline and does not change the oxidation energy substrates. In accordance with the literature may be suggested a potential 'saving effect' on liver glycogen. Bibliography Leslie Bonci. ### THE INFLUENCE OF A CARBOHYDRATE-ELECTROLYTE SOLUTION ON FLUID BALANCE AND PERFORMANCE IN NATIONAL LEVEL FENCERS DURING TRAINING

MARIDAKI, M., CHRYSSANTHOPOULOS, C., TSOLAKIS, C.K., TOUBEKIS, A.G., ZACHAROGIANNIS, E., TAMPAKI, M., THEOS, A., ROUSSOPOULOS, E., DOUSKAS, T., PAFILI, Z.

UNIVERSITY OF ATHENS

**Introduction** Ingestion of a carbohydrate-electrolyte solution helps maintain fluid balance and under certain circumstances may provide benefits over water (Sawka et al. 2007). However, such solutions have not been used in fencing. The purpose of this study was to examine a possible effect of a carbohydrate-electrolyte solution on fluid balance and performance in fencing. **Methods** Sixteen fencers, 12 men and 4 women, members of the Greek National team in epee [age: 21.4 ± 0.9 yrs, body mass (BM): 74.6 ± 3.3 Kg, height: 178 ± 2 cm, VO<sub>2</sub>max: 49.3 ± ml/Kg/min, and body fat: 15.1 ± 1 %; mean ± SE] performed two identical in content 120-min training sessions separated by 7-14 days under similar environmental conditions (temperature 20.3 ± 0.5 °C, and humidity 45-47 ± 2%). Fencers ingested at regular intervals a total volume of 23.5 ml/Kg BM of either a 6% carbohydrate-electrolyte solution (CE) or placebo (< 0.3%) (P) in a counterbalanced order. Each session consisted of a 60-min period for warm-up and conditioning exercises, and 10 games of 3 min duration against the same opponent with 3 min interval between each game. Urine and capillary blood samples were collected before and after each training session. **Results** There was no difference in the rate of perceived exertion, in the number of games won, or lost, or in the points for and against during the 10 games played between CE and P trials. BM was similar before exercise as well as after exercise between conditions. However, BM after training was maintained in CE (Before Exercise: 73.4 ± 3.2 Kg vs. After Exercise: 73.3 ± 3.2 Kg), whereas in P there was a 0.5 ± 0.1 % decrease (Before Exercise: 73.4 ± 3.2 Kg vs. After Exercise: 73.0 ± 3.1 Kg) ( $p < 0.01$ ). No differences were observed in heart rate responses, changes in plasma volume, creatinine and sodium content in urine as well as in the urine specific gravity between conditions. Blood glucose concentration was higher ( $p < 0.01$ ) post-exercise in CE (5.4 ± 0.3 mmol/l) compared to P (4.5 ± 0.2 mmol/l), whereas blood lactate concentration was no different between trials. **Discussion** The small decrease in BM observed in P may be due to the low sodium content compared to CE condition. The data show that the ingestion of the CE solution was as effective as water in terms of fencing performance during training at a thermo neutral environment. Further research is needed to examine whether sports drinks may provide benefits in fluid balance or performance in a warm environment. **References** Sawka MN, Burke LM, Eichner ER, Maughan RJ, Montain SJ, Stachenfeld NS. (2007). *Med Sci Sports Exerc*, 39, 377-90.

### INFLUENCE OF CARBOHYDRATE SUPPLEMENTATION ON THE FLUID AND ELECTROLYTE BALANCE DURING INTENSE INTERMITTENT TRAINING

SANDHOLTET, T., TREFF, B., SCHRADER, M., MAASSEN, M., KAESEBIETER, J., SHUSHAKOV, V., MAASSEN, N.

MEDICAL SCHOOL HANNOVER

Investigations of the effect of a beverage containing only carbohydrates on the electrolyte and fluid balance during intermittent exercise of high intensity are rare. Therefore we compared the effects of a supplementation of water and a carbohydrate solution on plasma and blood volume and electrolyte shifts during exercise. **Methods:** 11 male subjects (weight: 82.2 kg; height: 1.82 m, relative power: 4.3 W) performed an intermittent exercise test twice; in one trial tap water (4m /kg/15min) was consumed (Plac). In the other trial the same amount of water was ingested, however, Maltodextrin was added to achieve a 9.1 % carbohydrate solution (CHO). The mean intensity during exercise was 50% of the maximum power reached in an incremental test performed as a pre test. Training schedule: warming up with 50 % for 15 min. Afterwards power changed between 100% of the maximum power minus 10 W and 10 W each for 30 s. The intermittent exercise was performed until subjective exhaustion. Afterwards 10 min at 50% to cool down followed. Cubital venous blood was sampled to measure [Na<sup>+</sup>], [K<sup>+</sup>], [Cl<sup>-</sup>], [HCO<sub>3</sub><sup>-</sup>], osmolality, [Protein] in plasma, Hct, [Lactate], [Glucose], and [Hb]. Plasma volume changes were calculated from the changes of [Hb] and Hct. The changes in blood volume were derived from [Hb]. **Results:** Performance times were not different between the groups. No difference in heart rate and VO<sub>2</sub> between the trials could be detected. [Glucose] was significantly higher after Maltodextrin administration ( $p < 0.001$ ). Initially osmolality was similar in both trials however osmolality increased significantly more during CHO (interaction  $p = 0.002$ ). Blood volume decreased by about 4 % with under both conditions, however recovered partly during exercise under Plac (interaction beverage x time,  $p = 0.002$ ). 50 min after exercise blood volume reached the initial values under both conditions. The reduction of the plasma volume was slightly higher (5%). The time course. Under the different conditions the time course was similar to that of the blood volume ( $p = 0.024$ , beverage x time). MCHC showed a small but significant increase over time after carbohydrate ingestion (interaction  $p = 0.01$ ). 50 min after the end of exercise plasma volume reached the initial resting values, as well. No difference in the behaviour of [K<sup>+</sup>] could be detected between the trials however [Na<sup>+</sup>] and [Cl<sup>-</sup>] decreased with Plac (both  $p < 0.001$ ). In contrast to blood volume and plasma volume both electrolytes did not reach comparable concentrations after exercise under the different conditions. **Discussion:** Sole carbohydrate supplementation seems to stabilize [Na<sup>+</sup>] and [Cl<sup>-</sup>] in the plasma. This can not be explained simply by a co-transport of Glucose, Na<sup>+</sup> and Cl<sup>-</sup>, because that should lead to a recovery of the blood and plasma volume under CHO. In contrast this was found during exercise with Plac.

### EFFECTS OF BLOCK PERIODIZATION MODEL ON PERFORMANCE AND GLYCOGEN STORES IN RATS

DEARAUJO, G.G.1,2, PAPOTI, M.3, REIS, I.G.M.1, MELLO, M.A.R.3, GOBATO, C.A.1

1: UNICAMP (LIMEIRA, BRAZIL), 2 FIEL (LIMEIRA, BRAZIL), 3: UNESP (RIO CLARO, BRAZIL)

**Introduction** Current recommendations for the training periodization are based in concentrated loads (block periodization) due to large number of competitions during macrocycle. However, the comparisons among the protocols are hindered since innumerable factors such as internal/individual and external interferences may influence physiological parameters and performance. In an attempt to attenuate the external and internal interferences on physiological adaptations in the training, this study was undertaken to characterize the block periodized training (3 blocks during 12 weeks) in rats submitted to swimming exercise on anaerobic performance evaluated by exhaustion time, aerobic performance evaluated by lactate minimum test (LM) as well as the glycogen concentration in soleus muscle. It was hypothesized that the block periodization could be effective to increase the exhaustion time, aerobic capacity and the glycogen concentration in soleus in relation to sedentary group. **Methods** Seventy Wistar rats (60 days old) were randomly separated in two groups: Control/Sedentary (CT) and Block Periodization Training (BPT). The BPT lasted 12 weeks (w) with frequency of 6 days/w. The BPT

was subdivided in 3 blocks: Block 1 (6 w), Block 2 (4.5 w) and Block 3 (1.5 w). The blocks were subdivided in basic, specific and taper periods with intensities equivalent to body weight (% bw) ranging between 60 - 240% of individual anaerobic threshold determined by lactate minimum test (LM) and volume between 10-60 min. Results The exhaustion time (s) was measured with equivalent intensity to 13 % of body weight (% bw) and the aerobic capacity by LM test adapted for rats. The anaerobic performance was higher after Blocks 1 ( $76 \pm 29$  s), 2 ( $73 \pm 18$  s) and 3 ( $77 \pm 18$  s) than CT in respective period (6 w= $40 \pm 19$  s; 10.5 w= $49 \pm 21$  s; 12 w= $47 \pm 8$  s) but unchanged intra-group. The aerobic capacity evaluated by LM test unchanged after blocks 1 ( $4.67 \pm 0.50$  % of bw), 2 ( $4.30 \pm 0.42$  % of bw) and 3 ( $3.83 \pm 0.54$ ) in comparison to CT group in respective period (6 w=  $4.19 \pm 0.40$  % of bw; 10.5 w=  $3.80 \pm 0.41$  % of bw; 12 w=  $3.55 \pm 0.52$  % of bw). The glycogen stores in soleus increased after block 1 ( $0.745 \pm 0.213$  mg/100mg) in relation to CT in respective period (6 w=  $0.465 \pm 0.051$  mg/100mg) but unchanged after block 2 ( $0.345 \pm 0.105$  mg/100mg) and 3 ( $0.501 \pm 0.169$  mg/100mg) in relation to CT (10.5 w=  $0.381 \pm 0.102$  mg/100mg; 12 w=  $0.366 \pm 0.078$  mg/100mg). Discussion The BPT increased the anaerobic performance after the blocks in relation to sedentary rats but the aerobic capacity was unchanged when compared to CT group. Also, the BPT improved the glycogen stores after the block 1 but unaltered after block 2 e 3.

## EFFECT OF INTRANASAL INFUSION OF GALP ON FEEDING AND BODY WEIGHT REGULATION

TAKENOYA, F.1,2, SHIBA, K.1, KAGEYAMA, H.1, YAMAMOTO, N.3, RYUSHI, T.4, SHIODA, S.1

1:SHOWA UNIV.(TOKYO, JAPAN), 2:HOSHI UNIV.(TOKYO, JAPAN), 3: JAPANESE RED CROSS HOKKAIDO UNIV. (HOKKAIDO, JAPAN), 4: DAITO BUNKA UNIV.(SAITAMA, JAPAN)

Introduction Galanin-like peptide (GALP), a 60 amino acid neuropeptide (Ohtaki et al., 1999), is known to suppress feeding behavior and energy metabolism (Takenoya et al., 2003, Shioda et al., 2008). In order to use GALP as an anti-obese drug, it is important to determine whether or not GALP suppresses feeding behavior when it is administered noninvasively. Recently, we have reported that intranasal infusion of GALP is an effective route of administration for delivery into the brain (Nonaka et al., 2008). Therefore, in the present study, we tried to clarify the effect of intranasal infusion of GALP on feeding behavior and body weight loss. Methods Male C57BL/6 +/+ and ob/ob mice were given continuous intranasal infusion of the vehicle once a day for 7 days followed by of GALP (2 nM) once a day for 7 days, which inhibits GALP degradation. Body weight (BW), food intake, water intake and locomotor activity were measured for 7 days from the onset of the administration. Results In the lean mice, the BW was not significantly different between the GALP- and vehicle-treated animals with a slight reduction of both food and water intake. In the obese mice, the BW in the vehicle-treated group was gradually increased, but in the GALP-treated group it was unchanged. However, in the obese mice, food intake was started to decrease after the first intranasal infusion of GALP and reached the same level in the lean mice. GALP was significantly decreased the water intake and locomotor activity in the obese mice. Discussion The intranasal infusion of GALP decreased both food and water intake and suppressed a spontaneous increase in BW in the obese mice (Shiba et al., 2010). These results strongly suggest that intranasal infusion of GALP is an effective route to exert its effect as an anti-obesity drug and therapeutic exercise especially for obese people. ## CONFIRMATORY FACTOR ANALYSIS OF THE SELF-EFFICACY FOR FRUIT AND VEGETABLE CONSUMPTION SCALE IN GREEK YOUTH: TESTING THE ASSUMPTION OF EQUIVALENT STRUCTURE ACROSS GENDER

KARTEROLIOTIS, K.

UNIVERSITY OF ATHENS

Introduction Daily consumption of fruit and vegetables (FR&V) by youth is a behavior associated with an array of health benefits. For example, daily consumption of FR&V is typically associated with reduced risks of various types of cancer such as colon, lung, breast, and stomach cancer (Willet & Trichopoulos, 1996). Although current recommendations are for youth and adolescents to consume five or more servings of FR&V daily, evidence indicates that these recommendations are not being met. Since consumption of recommended amounts of FR&V may result in health benefits, research must identify theory-based determinants of this behavior. One determinant may be self-efficacy beliefs which are hypothesized to influence behavioral behavior. Recently, a valid and reliable task self-efficacy measure for fruit and vegetable consumption (SEFV) has been developed for American youth (Dzewaltowski et al., 2007). Thus, the purpose of this study was to evaluate the factor structure of the translated SEFV with a sample of Greek middle school children and to examine if they are any differences between boys and girls in the FR&V consumption behavior. Methods Participant were 556 middle school students (301 boys and 255 girls), aged 11-15 years, enrolled in 16 middle schools in a suburban area in Athens, Greece. Informed consent from students and their parents or legal guardians were obtained prior to the collection of the data. The SEFV consists of six items that assesses children's confidence in their skills and abilities to consume one to six or more servings of FR&V daily. Confirmatory factor analyses were performed using the FILM estimation in AMOS 7.0 Results Single group analyses indicated an acceptable two-factor structure model for both boys and girls. Multigroup analysis showed that factor structure, factor loadings, and unique variances of the self-efficacy for FR&V consumption scale were invariant across gender. Discussion The overall findings of the study supported the two-factor structure of the self-efficacy for fruit and vegetable consumption scale. Youths' confidence to consume FR&V at internationally recommended levels (factor 2) may be distinct from confidence to consume fewer (factor 1) servings daily. Further work is needed to validate its structure across age and also to examine the factorial and construct validity of the two-factor SEFV measure with other populations. ## USE OF PROTEIN SUPPLEMENTS AND DIETARY BEHAVIOUR: RESULTS OF A SURVEY ON PEOPLE ATTENDING COMMERCIAL GYMS IN ITALY

BIANCO, A., MAMMINA, C., PAOLI, A., CARAMAZZA, G., BELLAFFIORE, M., PALMA, A., JEMNI, M.

UNIVERSITY OF PALERMO, UNIVERSITY OF PADUA, SCUOLA DELLO SPORT CONI SICILIA, UNIVERSITY OF GREENWICH

Introduction Nutrition is traditionally perceived as a crucial component of physical fitness and performance. In the last few decades, the increasing understanding of human nutrition and exercise physiology has showed that a wise management of nutrient intake could positively affect fitness improvements and sport performance. The aim of this study was to examine the use of dietary supplements and

diet behavior amongst regular fitness centers users in Italy. Methods A specific questionnaire was generated for the experimentation. The data were collected using the face-to-face interview method. Only strength and conditioning classes participants were included in the selection criteria. Training information have been collected from 800 regular fitness center attendees; 207 of them were selected for the study. Analysis: Significance differences were assessed by one-way ANOVA, Kruskal-Wallis, chi-square test or exact test of Fisher when appropriate. Results Dietary supplements proved to be used by 30.1% of the respondents. Use of supplements was lasting on average  $2.6 \pm 3.3$  years without any significant difference by gender. Whey protein shakes (50.0%) mixed with creatine and amino-acids (48.3%) was the most frequent choice among users. Supplement non-users consumed more snacks and bakery than users per week ( $P < 0.001$ ). Conclusions A considerable number of regular strength training subjects consume protein supplements mixed with other supplements and high-protein foods, in particular meat. We emphasize the importance of the dissemination of scientifically based information about supplementation in the fitness centers and the promotion of updated education programs for fitness instructors. ### PP-PM69 Physiology: Inflammation/Redox

#### THE BLOOD REDOX STATUS OF ENDURANCE-TRAINED ADOLESCENTS

TONG, T.

HONG KONG BAPTIST UNIVERSITY

THE BLOOD REDOX STATUS OF ENDURANCE-TRAINED ADOLESCENTS Tong, TK. 1, Lin, H. 2, Nie, J. 3, Shi, Q. 3, Tian, Y. 4 1: HKBU (Hong Kong, China). 2: LNU (Dalian, China). 3: MPI (Macao, China). 4: CISS (Beijing, China) Introduction Adult athletes appear to have antioxidant defense either better or similar to that of non-athletes (Finaud et al., 2006). In contrast, prepubescent children who involved in athletic training exhibited increased oxidative stress and less antioxidant capacity compared to untrained counterparts (Gougoura et al., 2007). There is little information available regarding the adaptations of antioxidant system in adolescent athletes participated in endurance sports. This study investigated the effect of chronic endurance training on the blood redox status in adolescent runners and cyclists by comparing it with that of age-matched individuals. Method 36 adolescents [12 runners (Age:  $15.5 \pm 1.3$  yrs, tanner stage:  $3.3 \pm 0.9$ , training years:  $2.2 \pm 0.9$  yrs), 12 cyclists ( $15.3 \pm 0.7$  yrs,  $3.1 \pm 0.3$ ,  $2.4 \pm 0.6$  yrs), 12 untrained ( $15.9 \pm 0.5$  yrs,  $2.8 \pm 0.5$ )] were recruited. With 72 hrs re-trained from intense exercise, venous blood were taken for measuring serum malondialdehyde, xanthine oxidase (XO), total antioxidant capacity, reduced glutathione (GSH), superoxide dismutase, and catalase (CAT). Dietary intakes were also recorded. Results In comparison to untrained subjects, the body size of cyclists was bigger while runners were smaller. % body fat of the athletes was lower. For the redox status, the serum GSH, CAT and XO of cyclists ( $20.4 \pm 10.2$  mg.l<sup>-1</sup>,  $2.61 \pm 0.92$  U.ml<sup>-1</sup>,  $19.9 \pm 2.8$  U.l<sup>-1</sup>) were higher than runners ( $14.1 \pm 5.6$  mg.l<sup>-1</sup>,  $1.89 \pm 0.55$  U.ml<sup>-1</sup>,  $16.1 \pm 2.1$  U.l<sup>-1</sup>) and untrained ( $12.1 \pm 2.9$  mg.l<sup>-1</sup>,  $0.53 \pm 0.36$  U.ml<sup>-1</sup>,  $16.7 \pm 1.3$  U.l<sup>-1</sup>). The CAT of runners was also higher than untrained. Other biomarkers were not different. The intakes of macro-nutrients and micro-minerals including zinc, iron, and magnesium were greater in cyclists comparing with runners and untrained. Higher carbohydrate and lower cholesterol intakes were found in runners compared to untrained. Discussion In contrast to trained prepubescent children (Gougoura et al., 2007), adolescent runners and cyclists in this study did not exhibit augmented oxidative stress or inferior antioxidant capacity in comparison to those of untrained counterparts. Rather, a greater antioxidant defense was potentially found in cyclists compared to runners, indicating that chronic endurance training-induced adaptations of antioxidant capacity may be sport specific. Nevertheless, the factor of various dietary intakes to the difference in the redox status should not be neglected. Taken together, the current findings suggest that the effects of chronic endurance training on the blood redox status of adolescent athletes are in line with those observed in adult athletes. #### ANTIOXIDANT ENZYMES DEPLETION INDUCED BY INTENSIVE HANDBALL TRAINING

DJORDJEVIC, D.1, CUBRILLO, D.1, BARUDZIC, N.1, VULETIC, M.1, ZIVKOVIC, V.1, PUZOVIC, V.1, DJURIC, D.2, JAKOVljeVIC, V.1

1: FACULTY OF MEDICINE (KRAGUEVAC, SERBIA), 2: SCHOOL OF MEDICINE (BELGRADE, SERBIA)

Introduction Although it is clear that both anaerobic and aerobic exercise have the potential to result in increased production of prooxidants, there is still little information available regarding changes in redox state induced by mixed (anaerobic-aerobic) exercise, especially in adolescent and child athletes. The aim of our study was to assess the changes in redox state of adolescent handball players induced by intensive handball training, as well as to investigate if there is correlation between fitness level (expressed through aerobic power) and pro/antioxidant response to acute exercise. Methods 43 young handball players participated in the study. In the first part of the investigation athletes were subjected to maximal progressive exercise test to measure their maximal oxygen consumption. The second part of investigation consisted of blood sampling immediately before and after one and a half hour intensive handball training. Blood samples were used for redox state analysis which included measurement of nitric oxide (estimated through nitrites), superoxide anion radical, hydrogen peroxide, lipid peroxidation (estimated through thiobarbituric reactive substances), superoxide dismutase activity, catalase activity and glutathione levels. Results Handball training induced statistically significant decrease of athletes' superoxide dismutase activity and fall of glutathione levels. Catalase activity correlated negatively with levels of nitrites, hydrogen peroxide and index of lipid peroxidation both before and after handball training. Aerobic power (maximal oxygen consumption) correlated positively with catalase both before and after training and negatively with after-training levels of hydrogen peroxide and index of lipid peroxidation. Discussion The extent of redox homeostasis disturbance induced by acute bout of exercise depends on many factors, inter alia, exercise mode, intensity and duration (Fisher-Wellman and Bloomer 2009). Although levels of prooxidants of our subjects did not change significantly after exercise, the fact that superoxide anion dismutase activity and glutathione levels decreased significantly suggest that handball training induced increased free radical production which depleted levels of the first line antioxidants. Correlations found between aerobic power and pro/antioxidants support the assumption that fitness level correlates positively with desirable redox state (Chang et al. 2002; Djordjevic et al. 2011). ## EFFECT OF TRAINING LEVEL OVER OXIDATIVE STRESS AND ANTIOXIDANT RESPONSE AT DIFFERENT EXERCISE INTENSITIES

BRAZO SAYAVERA, J., OLCINA CAMACHO, G., MUÑOZ MARÍN, D., TIMÓN ANDRADA, R., ROBLES GIL, M.C., MAYNAR MARIÑO, M.

UNIVERSIDAD DE EXTREMADURA

**Introduction** Oxidative stress has been defined as a shift in the normal pro-oxidant – antioxidant balance in favour of pro-oxidants. Exercise is associated with oxidative stress, which can induce adverse effects on health and well-being (Finaud, 2006), as well as some long term adaptations (Kabasakalis et al., 2010; Olcina et al., 2006). The aim of this study was to analyse the oxidative stress and the antioxidant response during exercise at different intensities in groups with different aerobic training level. **Methods** The participants were: Well trained (n=20) VO<sub>2</sub>max 68,31±8,65 ml•min•kg<sup>-1</sup>, Trained (n=20) VO<sub>2</sub>max 45,91±7,54 ml•min•kg<sup>-1</sup> and Sedentary (n=20) VO<sub>2</sub>max 35,49±4,93 ml•min•kg<sup>-1</sup>. An incremental maximal test was performed on cycloergometer starting at 100 watts and increasing the workload each 3 minutes 25 watts until exhaustion. Venous blood was collected each three minutes. Plasma malondialdehyde (MDA) as oxidative stress marker and vitamins A and E as lipid environments antioxidants were determined by HPLC. Four points were chosen in order to compare the groups with different exercise duration (Initial, Aerobic Threshold, Anaerobic Threshold and Final). The ANOVA with repeated measured test was performed for statistical analysis. A p<0.05 was used to determine statistical significance. **Results** The highest values in MDA concentrations in the beginning were found in well trained subjects (2,85±0,99 µM/mL), while trained subjects presented higher vitamin A concentrations (0,74±0,23 µg/mL) than well trained and sedentary subjects. Finally, the highest values in Vitamin E were found in sedentary subjects (74,56±10,77 µg/mL). No significant differences were found in the kinetics analysis of MDA, vitamin A and vitamin E in trained and sedentary subjects. However, a significant decrease in MDA concentrations (2,85±0,99 to 2,68±0,92 µM/mL) and a significant increase in vitamin A (0,73±0,27 to 0,77±0,18 µg/mL) and vitamin E (52,28±11,89 to 57,19±12,79 µg/mL) were found in well trained subjects across the trial. **Discussion** Aerobic training causes adaptations to oxidative stress and in the antioxidant response system (Finaud, 2006). As higher is training level, higher is the oxidative stress. However, trained people are able to control the oxidative stress increase during short term efforts at different intensities although they have lower vitamin E levels at rest. Maybe they balance it with higher increase of vitamin A values (Kabasakalis et al., 2010; Olcina et al., 2006). **References** Kabasakalis A, Kyparos A, Tsalis G, Loupos D, Pavlidou A. (2010). ## EXERCISE AS A MODEL OF OXIDATIVE ASSAULT: THE ROLE OF PROTOCOL AND SAMPLING POINT

GRIVAS, G., NIKOLAIDIS, M.G., KYPAROS, A., DIPLA, K., PASCHALIS, V., THEODOROU, A.A., SAMPANIS, M., VRABAS, I.S.

ARISTOTLE UNIVERSITY OF THESSALONIKI

**Introduction** The development of a valid and robust physiological model to induce oxidative stress would be extremely useful in redox biology. Studies have shown that the effects of aging, obesity or nutrition intervention on redox homeostasis emerge, if not magnified, after having the participants subjected to an exercise stimulus. However, despite the fact that a physiological stimulus such as acute exercise is frequently used to produce a state of oxidative stress, rarely the chosen exercise model has been rigorously tested whether it suitably serves this purpose. For example, muscle damage induced by certain exercise modalities interferes with the time course and magnitude of oxidative stress. In addition, most of the available oxidative stress biomarkers have not been truly validated for the exercise setting. Therefore, the aim of the present study was to investigate the time-course changes of several commonly used markers of oxidative stress during a 96-h sampling period after an acute bout of either a non-muscle-damaging exercise or a muscle-damaging exercise. **Methods** Twenty physically active males ran either on a level treadmill (non-muscle-damaging condition) or on a downhill treadmill at -15% gradient (muscle-damaging condition) for 45 min at 70–75% VO<sub>2</sub>max. Blood and urine samples were collected before and post-exercise (immediately post, 1h, 4h, 24h, 48h and 96h). The following assays were performed: F2-isoprostanes in urine, protein carbonyls in plasma, GSH, GPX, SOD and catalase in erythrocytes. **Results** Both exercise conditions induced oxidative stress, yet in a unique way. In general, the changes in redox biomarkers were evident for up to 1 h after non-muscle-damaging exercise and returned to resting values thereafter. Conversely, there was a biphasic response in redox biomarkers (but GSH) after muscle damaging exercise. Changes were evident for up to 1 h after exercise, returned toward baseline values at 4 h post and altered again 24 – 96 h post exercise. **Discussion** To our knowledge, this is the first attempt to compare the short- and long-term oxidative stress responses of two exercise modalities that cause different degree of muscle damage in humans. The main findings are the monophasic oxidative stress responses detected after non-muscle-damaging exercise compared to the biphasic responses detected after muscle-damaging exercise. In fact, oxidative stress appeared immediately after muscle-damaging exercise and persisted for several days thereafter, as opposed to the early return to the resting values few hours after the acute non-muscle-damaging exercise. The present findings indicate that sampling time after exercise largely depends on exercise protocol and less so on biomarker examined.

## INFLAMMATORY RESPONSE TO CONTINUOUS VERSUS INTERVAL RUNNING

ENSENYAT, A.

INEFC-LLEIDA (UDL)

**INFLAMMATORY RESPONSE TO CONTINUOUS VERSUS INTERVAL RUNNING** Ensenyat, A. (1); Serrano, J. (2); Farreny, D. (1); Blanco, A. (1); Bellmunt, J. (3); Portero, M. (2); Pamplona, R. (2) 1: Laboratori de Valoració Funcional. INEFC-Lleida. UdL (Lleida, Spain) 2: Departament de Medicina experimental. UdL (Lleida, Spain) 3. Departament de Mèdiques bàsiques. UdL (Lleida, Spain) **Introduction** Prolonged exercise is associated with changes in plasma levels of inflammatory and anti-inflammatory markers, such as TNF-alpha, IL-6, IL-10, or CRP. Although several studies have examined the acute-phase reaction after continuous strenuous endurance-type exercise, few studies have reported changes of these markers in the blood after intervallic bouts. Therefore, the aim of the study was to analyse pro and anti-inflammatory time course and magnitude of changes to two training sessions of similar duration but different training purposes. **Methods** Five apparently healthy male physical education students (22,1 (SD:0,9) yrs of age, BMI = 22,2 (SD:1,04) kg/m<sup>2</sup>, VO<sub>2</sub>max= 57,3 (SD:10,5) ml/kg/min) completed two 60-min running workloads in a randomized cross-over design. Workload A consisted of continuous level run with a targeted heart rate of 90% individual anaerobic threshold (IAT); while workload B consisted of interval training (8 series of 4 min, with 2 min recovery) at 110% IAT's heart rate. Blood samples, for the determination of TNF-alpha, IL-6, IL-8, IL-10, CRP and SAA, were taken before, immediately after, and at 60 and 180 minutes post-exercise. Plasma concentrations of these analytes were assessed by a MILLIPLEX Map kit (MPXHCYT0-60K and HCVD-67BK, Millipore, MA, USA) **Results** Both training sessions had a similar total duration but differed

in intensity (speed=9,9 (SD: 1,1) km/h in session A versus 12,3 (SD: 1,6) km/h in session B; heart rate=165,5 (SD: 11,8) and 175,8 (SD: 9,2) bpm, respectively). Total load (sum of heart beats) was not different between sessions. In both sessions, IL-6, and TNF-alpha were significantly higher (84%; 59 %;  $p<0,05$ ) immediately post-exercise but IL6/TNF-alpha index was unchanged at any time-point. No significant effects were observed for SAA. IL-10 and CRP rose after continuous running, and remained significantly elevated (240%, 250%;  $p<0,05$ ) at 60' of recovery. They were not affected by interval running. No significant effects were observed for IL-8 after continuous moderate exercise, however, IL-8 rose (50%) significantly post-interval running and was still raised during early recovery. Discussion Findings indicate that plasma levels of several inflammatory and anti-inflammatory markers are elevated after 60' of continuous /interval running at either 90% or 110% of IAT's heart rate. However the balance between pro-inflammatory and anti-inflammatory indicators was unchanged and suggests that -regardless of intensity and distribution of workload inside the session- exercise protocols produced only a limited acute-phase reaction.

### PHYSICAL ACTIVITY, INFLAMMATION AND ADRENOPAUSE IN POST-MENOPAUSE

IZZICUPO, P.1, D'AMICO, M.A.1, DI FONSO, A.1, BASCELLI, A.1, DI BLASIO, A.2, D'ANGELO, E.2, NAPOLITANO, G.1, BUCCI, I.2, RIPARI, P.2, DI DONATO, F.2, GALLINA, S.2, DI BALDASSARRE, A.1

**Introduction.** Menopause is linked with several hormonal changes, in addition to the age-related physiologic decline of the dehydroepiandrosterone sulphate (DHEA-S) production. Further, a feedback cross-talk with raising systemic chronic inflammation might play a central role in these events. Women typically participate in less physical activity (PA) than men do but, even if physical activity has been shown to be correlated both with systemic inflammation and plasma DHEA-S level, it is difficult to establish whether these changes are due to both menopause and aging process per se or by lack of PA. Considering that after menopause, DHEA and DHEA-S are the main component of sex steroids, the aim of our study was to investigate the complex network among hormonal changes, pro-inflammatory mediators and PA, in post-menopause. **Methods.** Thirty-five sedentary post-menopausal women (55.9±4,2 years) were enrolled into the study. Basal plasma interleukin (IL) 1-alpha, IL1-beta, IL-2, IL-8, IL-10, IL-12p70 and tumor necrosis factor alpha (TNF-a) were measured by with SearchLight Human Cytokine Array 1. DHEA-S and leptin were measured by ELISA analysis. Body composition was assessed by electrical bioimpedance technique. Daily physical activity was measured, under free-living condition and for three consecutive days, through the SenseWear Pro3 Armband, giving information about total daily energy expenditure (TEE), mean daily physical activity intensity (METs) and both time and energy spent on physical activity with intensity >3 METs (tPA, PAEE). **Results.** TEE was found inversely correlated with IL1-alpha and IL1-beta ( $r=-.375$ ,  $P<0.05$ ;  $r=-.347$ ,  $P<0.05$ , respectively), METs with IL1-alpha ( $r=-.387$ ,  $P<0.05$ ), tPA with IL1-alpha, IL-2 and IL-10 ( $r=-.380$ ,  $P<0.05$ ;  $r=-.367$ ,  $P<0.05$ ,  $r=-.347$ ,  $P<0.05$ , respectively), and PAEE with IL-2 ( $r=-.358$ ,  $P<0.05$ ). A significant direct correlation was found among all measured cytokines. Even if neither TNF-a or DHEA-S were correlated with PA parameters, we found a strong relationship between TNF-a and DHEA-S ( $r=-.569$ ,  $P=.001$ ), also controlling for confounding factors such as age and leptin. **Discussion.** In conclusion, in sedentary post-menopausal women, the systemic inflammatory mediator TNF-a and the main adrenal steroid DHEA-S show an inverse relationship. Poor PA might play a role, affecting systemic inflammation and then DHEA-S production at various levels through the hypothalamus-pituitary axis, although evidences from other studies suggest an anti-inflammatory action by DHEA-S.

### LOADING INCREASES INTERLEUKIN-6 EXPRESSION IN HUMAN TENDON TISSUE IN VITRO

LEGERLOTZ, K.

UNIVERSITY OF EAST ANGLIA

**LOADING INCREASES INTERLEUKIN-6 (IL6) EXPRESSION IN HUMAN TENDON TISSUE IN VITRO** Legerlotz K. 1, Screen H.R.C. 2, Riley G.P. 1 1: University of East Anglia (Norwich, UK), 2: Queen Mary University of London (London, UK) **Introduction** Exercise is known to increase plasma IL6 levels. Whilst the exercising muscle is thought to be the major site of IL6 production (1), a dramatic increase in the interstitial concentration of IL6 has been found in the peritendinous tissue around the human Achilles tendon after running, pointing towards tenocytes as another possible source of IL6 synthesis (2). In a pilot study on bovine tendon, we confirmed that tendon tissue expresses IL6 in response to exercise, reporting a marked increase compared to very low pre-exercise levels (3). The aim of this study was to characterize the effect of a range of overloading conditions on sample fatigue, and to associate the degree of fatigue damage with IL6 expression in human tendon fascicles. **Methods** Fascicles were dissected from healthy human hamstrings tendon and cyclically loaded to 60% of max. strain for 5, 15 and 30min at 1Hz. The fatigue loading was followed by either a failure test to provide a measure of sample damage ( $n=10$ ) or further loading at 10% of max. strain (to mimic physiological conditions) for gene expression analysis at 6 or 24h ( $n=7$ ). Fascicles frozen directly after dissection and fascicles not fatigued but loaded at 10% of max. strain served as controls. RNA was extracted, reversed transcribed and analysed by qRT-PCR (Taqman Low Density Array). Genes were normalized to 18s. **Results** 5, 15 and 30min overloading decreased mean failure stress by 21, 28 and 34% respectively. However, due to high inter- and intrapersonal variability these differences were not significant. Compared to the directly frozen control fascicles, IL6 expression increased significantly 6h post loading in the 5 and 15min overloaded, as well as in the minimally loaded fascicles. **Discussion** In terms of structural integrity, human tendon fascicles were notably more fatigue resistant than bovine tendon fascicles (3). IL6 expression was induced early post loading. However, the threshold to induce IL6 expression appears to be rather low, as it was also induced in the minimally loaded fascicle, designed to serve as a control. Increased IL6 levels might facilitate tendon adaptation by regulating healing processes, as tendon healing has been shown to be impaired in IL6 knockout mice (4). However, since IL6 has been attributed both pro- and anti-inflammatory functions (5) it could play a role in either tendon adaptation or the development of tendinopathy. This highlights the importance of further investigation, as IL6 might be a potential target for therapeutic intervention. **References** (1)Steensberg et al.(2000) J Physiol 529:237-42. ### INTERLEUKIN LEVEL IN RATS' BLOOD AFTER TWO DIFFERENT BRIEF WHOLE-BODY VIBRATION PROGRAMS

PAWLAK, M., NOWAK, A., CELICHOWSKI, J., KRUTKI, P.

UNIVERSITY SCHOOL OF PHYSICAL EDUCATION

**Introduction** Vibration is a physiological mechanical stimulus affecting different structures of tissues and is recognized by special sensors located throughout those tissues. The literature concerning the effects of vibration on mammalian organism describes a wide spectrum of physiological effects, ranging from harmful impact on the living organism to a useful modality and an effective way to exercise musculoskeletal structures. The important criteria for distinguishing between those two states are specific amplitudes, frequencies, and lengths

of vibration training. The aim of this study was to describe the modulatory effect of two different brief whole-body vibration programs in rats on the concentration of selected pro- and anti-inflammatory interleukins in the blood. Methods Ten male Wistar rats, aged 6 months, were trained for 5 weeks using a brief whole-body vibration program (5 days a week, frequency: 50 Hz, amplitude: 2.5 mm). Five of them underwent vibration training as a single session lasting 30 s (group 1), and the other five animals were subjected to four vibration sessions lasting also 30 s and applied at 60 s intervals (group 2). Animals in those vibrated groups were compared to age-matched control rats of the same age (n=5). After completing the training, blood was taken from all animals. Using the ELISA method, the level of two pro-inflammatory (IL-1 $\beta$ , IL-6) and one anti-inflammatory (IL-10) interleukins were determined. Results The concentrations of pro-inflammatory interleukins in the blood measured after the brief whole-body vibration were about 1 and 3 times higher, compared with the control animals, in the group subjected to one and to four vibration sessions, respectively. The level of interleukin-10 showed an opposite trend, decreasing 3 times, from 36.8 to ca. 12 pg/ml after the vibration program, and that effect was stronger in rats subjected to four vibration sessions (p<0.05). Discussion The brief whole-body vibration program led to higher concentration of both pro-inflammatory interleukins measured in the blood of rats (IL-1 and IL-6), however, the increased level of them was associated with the higher intensity of the applied vibration training. A parallel finding in this study was a decreased level of the IL-10 anti-inflammatory interleukin, which is perhaps a clear immunological message indicating the biological impact of vibration stimuli on a living organism.

## EFFECTS OF MODE AND INTENSITY ON THE ACUTE EXERCISE-INDUCED IL-6 AND CRP RESPONSES IN A SEDENTARY, OVERWEIGHT POPULATION

MENDHAM, A.

CHARLES STURT UNIVERSITY

Effects of mode and intensity on the acute exercise-induced IL-6 and CRP responses in a sedentary, overweight population Mendham AE; Donges CE; Liberts EA; Duffield R School of Human Movement Studies, Charles Sturt University, Australia Introduction Acute exercise may be an impetus for the inhibition of chronic disease development via the inducement of post exercise inflammatory responses (Kramer and Goodyear, 2007). Anti-inflammatory contributions during acute exercise have shown to be associated with enhanced metabolic function in both non-insulin dependent diabetes mellitus and normo-glycaemic subjects (Kramer and Goodyear, 2007). Therefore, the aim of this study is to investigate the acute exercise-induced plasma IL-6, CRP and total leukocyte count to different modes (resistance or aerobic) and intensities (higher or lower), within a middle aged, sedentary and disease-free subject population. Methods Following baseline testing, and in a randomized cross-over design, 12 sedentary males completed four exercise protocols, including 40 min of moderate-vigorous (M-VA, 50% maximal aerobic workload) or low-intensity (LA, 30% maximal aerobic workload) aerobic exercise on a cycle ergometer; and a moderate-vigorous (M-VR, 80% 1RM) or low-intensity (LR, 60%1RM) full-body resistance session matched for protocol duration, with HR and RPE collected during each session. Venous blood was obtained pre-, post-, 3 h post and 24 h post-exercise and analysed for IL-6, CRP, leukocyte count, myoglobin, creatine kinase (CK), and cortisol. Results HR and RPE showed no significant differences between modes of the M-V protocols or the low-intensity protocols. However, the M-V protocols were respectively higher than the lower-intensity. The 3–24 h post-exercise response of CRP was higher in the M-VR ( $0.68 \pm 0.31$  mg/L;  $80.0 \pm 38.2\%$ ) protocol when compared to the low-intensity protocols (P<0.05); however, no significant difference existed between the respective M-V intensity protocols. The M-V intensity protocols induced significant increases of IL-6, cortisol, and leukocytes in comparison to the low-intensity protocols (P<0.05). Additionally, a significant pre to post change in IL-6 was evident within the M-VA ( $0.9 \pm 0.13$  pg mL<sup>-1</sup>;  $70.9 \pm 4.5\%$ ; P = 0.0001) and M-VR ( $0.74 \pm 0.27$  pg mL<sup>-1</sup>;  $59.1 \pm 2.8\%$ ; P = 0.01), with no significance between the respective protocols, despite the M-VR inducing the largest response of markers indicative of muscle damage (CK, myoglobin, and neutrophil count) (P<0.05). Discussion A disassociation between the IL-6 response and markers of muscle damage within the respective exercise bouts was evident. Additionally, the highest IL-6 response was occurred in the M-V intensity protocols immediately post-exercise. Consequently, it appears the exercise modality did not overtly influence the acute IL-6 and CRP response, with the main determinant of the IL-6 response being exercise intensity when duration is standardized. ## INFLAMMATORY BIOMARKERS CHARACTERIZATION IN YOUNG BASKETBALL PLAYERS AT THE PREPARATORY PERIOD

BRUNELLI, D.T., SOUZA, T.M.F., BORIN, J.P., RODRIGUES, A., MONTAGNER, P.C., DANIEL, J.F., CAVAGLIERI, C.R.

STATE UNIVERSITY OF CAMPINAS

INFLAMMATORY BIOMARKERS CHARACTERIZATION IN YOUNG BASKETBALL PLAYERS AT THE PREPARATORY PERIOD Brunelli, DT. 1, Souza, TMF.1 Borin, JP.1, Rodrigues, A.1, Montagner, PC.1, Daniel, JF.1, Cavaglieri, CR.1 1: State University of Campinas (UNICAMP), Brazil. Introduction Nowadays, it is fundamental that proper training for young athletes in any field of physical activity should be aware of the changes in skeletal muscle brought on by strenuous training. Accordingly, an understanding of these various changes in the human system will help to determine, control and monitor training programs. In particular, the immunological and metabolic systems can reduce the performance level, and influence the development process and the good health of young athletes. Thus, the aim of this study was to investigate the immunological system responses of young basketball players at the preparatory stage. Methods Sixteen young males ( $13 \pm 0.63$  years;  $53.65 \pm 12.86$  kg;  $167 \pm 0.09$  cm). The training sessions were carried out 3 days per week, each session totaling 120 minutes comprising 15 min. of warm up; 90 min. of technical/tactical aspects and 15 min. of stretching). Blood samples (10ml) were collected from the antecubital vein into tubes (Vacutainer; Becton Dickinson, Mountain View, CA) before the period (M1) and after 8 weeks, at the end of the preparatory period (M2), and the total and differential leukocyte counts performed successively. Tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ) and prostaglandin (PGE2) were performed by ELISA (R&D Systems, Minneapolis, MN). To identify the differences between moments of modification, one-way ANOVA was applied. Where a significant main effect and/or interaction was observed, Tukey's HSD post hoc test was carried out (p<0.05). Data are presented in terms of means  $\pm$  standard deviations. Results Significant changes were found in monocytes (M1=902.25 $\pm$ 108.88; M2=442.63 $\pm$ 83.53) (p=0.00233) and prostaglandin (M1=952.07 $\pm$ 109.09; M2=404.84 $\pm$ 75.41) (p=0.000393). No differences were found in total leukocyte counts (M1=9075 $\pm$ 483; M2=8225 $\pm$ 430.84), neutrophils (M1=4603.63 $\pm$ 431.62; M2=4823.5 $\pm$ 275.82), lymphocytes (M1=3194.38 $\pm$ 233.31; M2=2732 $\pm$ 159.43) and TNF- $\alpha$  (M1=1.47 $\pm$ 0.41; M2=1.53 $\pm$ 0.39). Discussion Exercise can promote physiological and metabolic stress, which provokes a defensive reaction in the organism such as inflammation, to recover from these changes, with cytokines acting as an intermediating agent on cellular alterations (KELLEY, 2001). According to the data observed in this study, the decrease in monocytes and prostaglandin after the preparatory period suggest adaptive behavior on the part of the volunteers as a result of the load training applied during the period. **INFLAMMATORY RESPONSE AFTER AN ACUTE STRENGTH PROTOCOL IN TRI-SET**

BRUNELLI, D.T.1, LIBARDI, C.A.1, CAVAGLIERI, C.R.1

STATE UNIVERSITY OF CAMPINAS

**INFLAMMATORY RESPONSE AFTER AN ACUTE STRENGTH PROTOCOL IN TRI-SET** Brunelli, DT.1, Libardi, CA.1, Cavaglieri, CR.1 1: State University of Campinas (UNICAMP), Brazil. **Introduction** Microtraumas are temporary damage which results in an acute inflammatory response produced by neutrophils, macrophages and cytokines which perform the function of repairing the tissue damage (SMITH, 2000). Few studies have investigated the immune and inflammatory responses in light of different strength training protocols. Thus, the aim of this study was to investigate the reaction of cortisol, pro-inflammatory cytokines and immune cell counts to an acute strength protocol in tri-sets. **Methods** Nine trained males were recruited ( $22 \pm 1.87$  years;  $80 \pm 8$  kg;  $175 \pm 5$  cm). The one repetition maximum (1RM) was determined for each exercise performed. After 72 hours of rest, individuals were submitted to a strength training protocol with multiple sets (Tri-set). Two combinations were determined: 1) bench press, incline bench press, dumbbell fly. 2) EZ bar curl, dumbbell biceps curl, Scott machine. Volunteers performed 6 sets with 75% of 1RM for each exercise, 3 passages in each combination and 3 minutes rest between passages. The blood samples were collected from the antecubital vein before the session (M1), after the session (M2), 24 hours after the end of session (M3), and the total and differential leukocyte counts ( $\text{cel}/\text{mm}^3$ ) performed successively. Cortisol ( $\text{pg}/\text{ml}$ ) was measured by serum with the Electrochemiluminescence method. Interleukin-6 (IL-6) and tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ) ( $\text{pg}/\text{ml}$ ) were performed by ELISA. One-way ANOVA and Tukey's HSD post hoc test were applied ( $P < 0.05$ ). **Results** Significant differences were found in total leukocyte count ( $M1 = 9877.77 \pm 2498.88$ ;  $M2 = 15000.00 \pm 2672.07$ ;  $M3 = 8855.55 \pm 1785.43$ ), Monocytes ( $M1 = 877.44 \pm 307.65$ ;  $M2 = 2768.22 \pm 523.96$ ;  $M3 = 633.72 \pm 235.83$ ) and neutrophils ( $M1 = 6200.11 \pm 1973.57$ ;  $M2 = 9105.00 \pm 2116.75$ ;  $M3 = 5338.16 \pm 1349.13$ ). No differences were found in lymphocytes ( $M1 = 2517.00 \pm 628.49$ ;  $M2 = 2769.66 \pm 756.73$ ;  $M3 = 2562.33 \pm 473.12$ ), IL-6 ( $M1 = 1.21 \pm 0.91$ ;  $M2 = 1.30 \pm 0.89$ ;  $M3 = 1.15 \pm 0.74$ ), TNF- $\alpha$  ( $M1 = 2.29 \pm 1.61$ ;  $M2 = 2.57 \pm 1.72$ ;  $M3 = 2.35 \pm 1.62$ ) and cortisol ( $M1 = 2.35 \pm 1.62$ ;  $M2 = 13.30 \pm 4.07$ ;  $M3 = 12.88 \pm 3.40$ ). #Significant differences compared to M1. **Discussion** The mechanisms responsible for the leukocytosis after resistance exercise are not fully understood, but the evidences suggests sympathetic nervous activity, catecholamines and cortisol as mediators of this process (Koch, 2010). However, the leukocytosis found in our study was transitory and probably in response to the action of catecholamines. Furthermore, the intensity in the present protocol was not able to promote a transient immunosuppression, probably because they were trained, since we not found significant changes on lymphocytes and cytokines. **References** SMITH, L. **Introduction:** The anaerobic capacity is a critical factor in many athletic disciplines. However there are fundamental difficulties in modelling the maximum amount of ATP that can be generated through anaerobic substrate metabolism. Therefore the purpose of this study was to examine the validity of using an all-out peak power cycle test for the determination of the anaerobic capacity. **Method:** Following local institutional ethics approval 9 well-trained male athletes volunteered to participate (age  $21.8 \pm 2.1$  yrs, mass  $74.2 \pm 12.7$  kg, height  $178.8 \pm 7.4$  cm,  $\text{VO}_{2\text{max}}$   $62.9 \pm 7.7$  ml/kg/min). Each participant visited the laboratory on four separate occasions separated by at least 72 hr for the determination of  $\text{VO}_{2\text{max}}$ , sub-maximal  $\text{VO}_2$ , maximally accumulated oxygen deficit (MAOD) and all-out peak power (aoPP) (anaerobic capacity). 4 of the participants completed an additional aoPP test for determination of reliability. All exercise trials were completed on an electronically braked cycle ergometer. The MAOD was determined according to (Medbø et al., 1988). For the aoPP trials participants cycled maximally against a fixed resistance ( $0.7 \text{ Nm}/\text{kg}$ ) until power output declined to the power at  $\text{VO}_{2\text{max}}$ . For aoPP, energy outputs (KJ) were calculated by trapezia measurements of the area under the total power output (tPO) and aerobic power output (aPO) curves until their point of intersection, with anaerobic energy generation =  $\text{tPO} - \text{aPO}$ . Throughout all trials expired air was recorded on a breath-by-breath basis using a pre-calibrated metabolic cart. **Results:** The mean MAOD score was  $60.7 \pm 14.2$  ml/kg or  $22059 \pm 6445.0$  J with a duration of  $118.1 \pm 51.1$  s, which equated to a workload of  $465.1 \pm 80.9$  W. For the aoPP test the mean energy generation score was  $24.8 \pm 5.9$  KJ or  $332.0 \pm 74.0$  J/kg. The duration of the aoPP test was  $51.9 \pm 16.4$  s with a total energy cost of  $23087.3 \pm 7057.1$  J. There was a significant difference for both test duration ( $P = 0.00280$ ) and exercise intensity ( $P = 0.0013$ ) between MAOD and aoPP. There was however a non-significant difference between MAOD and aoPP (J) ( $P = 0.1621$ ). Test re-test analysis of the aoPP displayed a SEM of  $1.72$  KJ which equated to a CV of 5.7%. **Discussion:** The data suggests that the aoPP test may provide a valid means of estimating the anaerobic capacity. In all participants the power output declined from the instantaneous high to that associated with  $\text{VO}_{2\text{max}}$ , but then displayed a 'plateau like' response suggesting that the aoPP test has both exhausted the anaerobic capacity and factored in the aerobic contribution. **References** Medbø JI, Mohn AC, Tabata MI, Bahr R, Vaage O, Sejersted OM. **INDIVIDUAL ANAEROBIC THRESHOLD ASSESSMENT IN FRONT CRAWL SWIMMERS**

RIBEIRO, J., SOUSA, J., VILAS-BOAS, J.P., FERNANDES, R.J.

FACULTY OF SPORT, PORTO UNIVERSITY

**Introduction** One of the most used methods for anaerobic threshold assessment is based on the fixed reference value of 4 mmol/l of blood lactate concentration ([La]). However, since 30 years ago, the anaerobic threshold has been reported to have great variability between athletes, particularly swimmers (Stegmann et al, 1981; Fernandes et al, 2008). In fact, a fixed value of [La] does not take into account considerable inter-individual differences and may frequently underestimate or overestimate real aerobic capacity. Thus, conversely to the use of an averaged [La] value, an individualized approach was suggested before, both for adult (Fernandes et al., 2008) and children swimmers (Fernandes et al., 2010). The purpose of the present study was to assess the individual anaerobic threshold in front crawl swimming. **Methods** In a 50 m swimming-pool, 13 international level swimmers ( $20.7 \pm 2.7$  years old,  $182.8 \pm 6.0$  cm,  $74.6 \pm 5.2$  kg and  $n > 8$  training units per week) performed a  $7 \times 200$  m individualized intermittent incremental protocol, with increments of  $0.1 \text{ m}/\text{s}$  for each 200 m step (1 min rest intervals), being the initial velocity established according to the individual level of performance on the 400

m front crawl (adapted from Fernandes et al., 2008). Capillary blood samples, collected during the intervals (Lactate Pro, Arkay Inc), allowed assessing individual anaerobic threshold through the [La]/velocity curve modelling method (assumed to be the interception point of a combined pair of regressions used to determine the exact point for the beginning of an exponential rise in [La], as proposed by Machado et al., (2006). Results [La-] and velocity values corresponding to individual anaerobic threshold averaged, respectively,  $2.32 \pm 0.68$  mmol/l and  $1.38 \pm 0.11$  m./s-1, being both significantly lower than the averaged 4 mmol/l of [La] and corresponding velocity values. Discussion Our results corroborate those previously observed for well aerobically trained swimmers (cf. Stegmann et al., 1981; Martin and White, 2000; Fernandes et al., 2008). These authors observed that the [La] corresponding to anaerobic threshold in groups of untrained subjects or athletes not especially aerobically trained was found near 4 mmol/l, but in aerobically trained subjects (especially in highly trained long-distance runners, triathletes and swimmers), it was found to be distinctively lower. Therefore, we confirm the fact that the 4 mmol/l and its corresponding velocity values do not represent the individualized lactate threshold in trained swimmers. References Fernandes RJ et al. ## RELIABILITY OF BLOOD LACTATE REMOVAL AND PERFORMANCE DURING SWIMMING

DE LUCAS, R., MEGDA, T.H., GUGLIELMO, L.G.A., DENADAI, B.S.

FEDERAL UNIVERSITY OF SANTA CATARINA

Introduction During most of swimming competitions, the athletes are asked to participate of multiples bouts at the same day, turning important the recovery mode realized between these performances. Many studies have been made to investigate the best intensity of this recovery, and also the effects of different recovery modes (passive, active or combined) in lactate removal (Reaburn and Mackinnon, 1990; Toubekis et al., 2008). The purpose of this study was to investigate the reliability of the lactate removal rate in swimming using two different recovery modes (passive and active) and also of 200m-performance. Methods Nine competitive swimmers participated in this study. They performed a 200m swimming max effort, to induce acidosis, and recovered for 30min. All of recovery modes tests and retests, were randomized and realized with at least 24h between them. The blood lactate [La] was collected on minutes 1, 3, 5, 7, 9, 13, 17 and 30. During these tests the lactate parameters were observed: half time of blood lactate removal (t1/2); maximal blood lactate concentration ([La]max); time to reach maximal blood lactate removal (time to [La]max); 200m swimming performance time (T200m). Statistical Analysis was made by t-test, intra-class correlation and typical error of measurement (TEM), between test and retest for each mode of recovery (Hopkins, 2000). Results The mean $\pm$ s values of t1/2 during passive and active recovery were  $16.55 \pm 2.82$ min e  $10.92 \pm 4.65$ min, respectively, not showing significant difference between test and retest on each recovery mode. However, a weak correlation was found (passive:  $r=0.09$ ; active:  $r=0.45$ ), and also a high TEM for both mode of recovery (passive: 22%; active: 37%), thus not assuming the reliability of this index on swimming. All of other lactate indices analysed showed TEM higher than 10% (12-38%). Furthermore, the T200m could be considered highly reliable for both recovery modes, showing the mean $\pm$ s values of  $145.1 \pm 12.6$ s, correlation of 0.98, and TEM of 1,5% Discussion Although the mean values of the lactate parameters analysis (t1/2; [La]max; time to [La]max) did not show significant difference between test and retest, both analysis of correlation and TEM showed low reliability for two mode of recovery. The mechanisms involved in the lactate production and particularly on blood lactate removal, seem to vary from one day to another, when analyzing the intra-subject variations. Thus, we suggest carefulness when using the t1/2 of blood lactate removal in swimming, whether for research or practical applications. References Hopkins, W. (2000) Sports Med. 30, 1-15. ## RELATIONSHIP AMONG TRAINING LOAD, LACTATE MINIMUM AND PERFORMANCE IN TRAINED CYCLISTS DURING A FULL TRAINING PERIOD

FERRARI, H.G.1,2, GOBATO, C.A.3, MANCHADO-GOBATO, F.B.2

1:FIEL (LIMEIRA, BRAZIL) 2:UNIMEP (PIRACICABA, BRAZIL) 3:UNICAMP (CAMPINAS, BRAZIL)

Introduction The correct distribution of load during period training is essential to improve physical capacity and performance of athletes. The main components to training load are volume and intensity, although the intensity appears to be most important to well trained athletes (Iaia and Bangsbo, 2010). Therefore, the aim of the study was to verify the relationship among training load, aerobic capacity and performance in trained cyclists. Methods Eight well trained road cyclists (age  $18 \pm 2$  years; weight  $64.9 \pm 8.6$  Kg) were submitted to the experimental protocol. The full training period was divided in three phases: preparatory (1st to 9th week), first competitive phase (10th to 18th week) and second competitive phase (19th to 29th week). The training load, considered as the product of the volume (Km) and intensity (km/h), was measured daily after each training session. The anaerobic threshold was determined by the lactate minimum test (LM) performed on a cycle ergometer using protocol modified by Pardonno et al. (2008). This protocol consisted in a hyperlactemia induction by Wingate test, followed by incremental test (six stages of 3 minutes) applied after 8 minutes of rest. The simulated time trials of 15 kilometers (TT-15km) were used to evaluate the performance. The LM and TT-15km were performed at the end of each training phase. Correlations among variables were obtained from Pearson Correlation test ( $P < 0.05$ ). Results There was no significant correlation among volume and training load with LM and TT-15km in all phases of training. However, significant correlation was obtained between intensity training and LM ( $r = 0.69$ ,  $P < 0.05$ ) in first competitive phase. The intensity training also showed significant correlation with TT-15km in first competitive phase ( $r = 0.76$ ) and second competitive phase ( $r = 0.70$ ). Discussion In elite athletes the training based in high intensity and low volume seems to be more efficient than high-volume and low intensity to increase anaerobic threshold and performance (Faude et al., 2008). Therefore, the significant correlations obtained among intensity, LM and performance suggest that the increase in the intensity during training appears to be efficient to improve aerobic capacity and performance in trained cyclists. ## EFFECTS OF STRAIGHTNESS KNEE KICK MAKES LACTATE ON 100 BUTTERFLY PERFORMANCE: A CASE STUDY USING THE MEN'S ASIAN AND JAPANESE RECORD HOLDER

IDE, T.

OSAKA UNIVERSITY OF HEALTH AND SPORTS SCIENCES

**INTRODUCTION** The stroke technique was focused on straightness the knees less (Maglischo, 2003). When comparing his 2005 stroke to his 2009 stroke, we found that the extent to the straightness of his butterfly kick improved (Ide et al, 2010) from 39% to 55% (of >170 degrees knee-bending). Lactate level of bending the knees at 4.3mmol/l, straightness knees at 6.4mmol/l. **METHODS** This study compared Kawamoto's performance in 2009 to his performance in 2005. Kawamoto performed 25 meter butterfly all out butterfly stroke. Swimming Speed Mater (Vine, VMS-003, AC100V, 1/500sec, 0.2mm/pulse) generated the data by an attached wire with movement place (Yoshimura et al., 2007). The wire then exports the analogue signals and RS232C signals. These signals calculated are then examined using Microsoft Windows Excel and a Wicoxon Signed Ranked Test. While swimming, the subjects were monitored from the side using an underwater video camera at a sampling frequency of 60Hz (Underwater monitor system 2, YAMAHA, Shizuoka, Japan). The subject strokes angle of degree was analyzed with DartTrainer in regards to the bending of the knee and upper body movement. The lactate test was 50seconds wall kick, tempo was 1.10sec/stroke by FINIS tempo machine. The subject lactate generated by the Lactate Pro™ (Kyoto, Japan) meter for on-farm determination of the blood lactate of teleost fishes. Blood lactate of farmed cod, caught by rod and line, was below detection limits of the meter (< 0.8 mM), and confirmed by laboratory assay as  $0.459 \pm 0.037$  mM (mean  $\pm$  SEM,  $n = 34$ ). **RESULTS** Swimming Speed Mater shows the 2009 and 2005 max speed was 2.5m/sec to 2.7m/sec at the second kick phase respectively. The distance pre stroke (DPS) results were different resulting in a,  $2.204m \pm 0.131$  for 2009 and  $1.894m \pm 0.062$  for 2005 (DPS (m) Wicoxon.:  $p=0.006061$ , 1 stroke (velocity) Wicoxon.:  $p=0.7748$ ) and DartTrainer showed the straight knee considered when the knee bend is 170 degrees to 180degrees (+170 degree), 55% use of straight knee kick for 2009 and 39% for 2005, in the one stroke. The lactate, bend knees test result at 4.3mmol/l, straightness knees test result at 6.7mmol/l. **DISCUSSION** Based on the above evidence it is clear the most preferred butterfly technique is to use a straight knee kick (Loebbecke et al., 2009). The other hand, straight knees kick makes more lactate. Next training plan (Yoshimura and Kosuge, 2008), we employed training plan for keep low lactate straight knee kick. **REFERENCES** Maglischo EW (2003). Swimming Fastest. Champaign: Human Kinetics. ## CAN MAXIMAL LACTATE STEADY STATE BE ESTIMATED THROUGH CRITICAL VELOCITY IN HUMAN SWIMMING?

ESPADA, M., ALVES, F.

FACULTY OF HUMAN KINETICS - TECHNICAL UNIVERSITY OF LISBON

**Introduction** Theoretically, critical velocity (CV) represents the highest velocity that can be sustained from aerobic energy reconstitution capacity in long duration events. Maximal lactate steady state (MLSS) has a real physiological meaning compared with CV but is associated with many difficulties related to his determination. The aim of the present study was to analyze the relation between MLSS and CV. **Methods** Seventeen well-trained male swimmers completed a maximal 400 m front crawl (mean performance 79% of world record) in order to use the average velocity between 50 m and the 350 m (V400) as an estimate of the maximal aerobic speed (Lavoie and Leone, 1988). For MLSS velocity (MLSSv) determination, athletes performed in random order and different days, 30-min at constant velocity at 85, 90 and 95% of V400. CV was calculated from the slope of the regression analysis between the velocity of maximal trials (100, 200, 400 and 800 m). CV2 corresponded to the relation of 200 and 400 m, CV3 to 200, 400 and 800 m and finally, CV4 to 100, 200, 400 and 800 m. Anaerobic Work Capacity (AWC) was represented by the y-intercept of the velocity-time relationship. Results MLSSv ( $1.34 \pm 0.06$  m.s<sup>-1</sup>) corresponded to 95% of CV2 ( $1.41 \pm 0.08$  m.s<sup>-1</sup>), 97% of CV3 ( $1.39 \pm 0.08$  m.s<sup>-1</sup>) and 96% of CV4 ( $1.40 \pm 0.08$  m.s<sup>-1</sup>). MLSSv, V400 and all critical velocities were highly correlated. T-test applied to MLSSv over CV determined from two, three and four swimming distances evidence that the designated "gold standard" was significantly lower when compared to any of the combinations to obtain CV ( $p < 0.01$ ). The linear regression relation between CV2, CV3 and CV4 lead us to conclude that CV can be determined for swimming through any of these swimming distances combination. AWC calculations were not related with any swimmer performance but we were able to verify that swimmers who performed faster in 100 m were those who present a higher AWC. **Discussion** In swimming, previous researches related to CV were quite conflicting with some authors arguing that represent the upper limit of heavy intensity exercise. We found that CV over-estimated MLSSv in well-trained swimmers as previous mentioned by Dekerle et al. (2005) in a study with eight trained competitive swimmers. Our results confirm that the direct determination of MLSSv remains the most accurate procedure for exercise prescription aiming at aerobic loading. We also verified that the inclusion of 800 m distances had no significant effect on CV determination that can result from the combination of 200 and 400 m maximal swims. Studies concerning CV have to be interpreted with caution, swimming CV is still a valuable tool to assess training adaptations and could be used as an estimator of the MLSSv. **References** Dekerle, J., Pelayo, P., Clipet, B., Depretz, S., Lefevre, T., Sidney, M. ## CAN AN INCREMENTAL TEST PROVIDE RELIABLE INDICATORS OF MAXIMAL LACTATE STEADY STATE?

ESPADA, M., ALVES, F.

FACULTY OF HUMAN KINETICS - TECHNICAL UNIVERSITY OF LISBON

**Introduction** Maximal lactate steady state (MLSS) is widely used for aerobic training prescription and monitorization of swimmers evolution. Lactate threshold (LT) represents the point during an incremental exercise test where there is an abrupt increase in blood lactate concentration [La] above basal levels. The purpose of this research was to compare the results obtained from an incremental test for LT determination with MLSS. **Methods** Fourteen competitive male swimmers completed a maximal 400 m front crawl in order to use the average velocity between 50 m and the 350 m (V400) as an estimate of the maximal aerobic speed (Lavoie and Leone, 1988). For MLSS velocity (MLSSv) determination, subjects performed, in random order and different days, 30-min at constant velocity at 85, 90 and 95% of V400. Athletes also completed 7x200 m front crawl incremental step test for LT determination based on log-log methodology (Pyne et al., 2001). Vmax was assumed as the swimming velocity performed in the last repetition of the incremental test. V4 was the velocity associated to a [La] of 4 mmol.L<sup>-1</sup>. Results Vmax ( $1.53 \pm 0.07$  m.s<sup>-1</sup>), V400 ( $1.52 \pm 0.07$  m.s<sup>-1</sup>), V4 ( $1.36 \pm 0.07$  m.s<sup>-1</sup>) and LT velocity (LTv) ( $1.34 \pm 0.06$  m.s<sup>-1</sup>) corresponded, respectively, to 112% (both Vmax and V400), 100% and 99% of MLSSv ( $1.36 \pm 0.06$  m.s<sup>-1</sup>). Vmax, V400, V4, LTv and MLSSv were highly correlated. LTv was different from MLSSv ( $p < 0.05$ ). Mean [La] at MLSSv ( $4.8 \pm 1.6$  mmol.L<sup>-1</sup>) was not related with mean [La] at LTv ( $3.7 \pm 0.7$  mmol.L<sup>-1</sup>). Velocity, stroke rate and stroke length performed in the fourth repetition of the incremental test (85%

of V200) were highly correlated with the same swimming parameters evidenced at MLSSv (respectively  $r = 0.87$ ;  $r = 0.89$  and  $r = 0.92$ ;  $p < 0.01$ ). The relation between MLSSv and V4 was examined with Blant Altman methodology, the bias and limits of agreement were indicators of a good fit. Discussion V4 was the physiological concept that more consistently estimated MLSSv. From our results we can conclude that V400 can be determined with accuracy from Vmax. Dekerle et al. (2005) found a decrease in stroke length at intensities above MLSS. We found this boundary to be situated at 90% of V400 and 85% of V200. In our understanding, both the continuous and incremental tests provide useful indexes of aerobic potential, but they cannot be used interchangeably for MLSSv estimation. The direct determination of MLSSv remains the most accurate procedure for exercise prescription aiming at aerobic loading. ### MAXIMAL AEROBIC POWER AND LACTATE THRESHOLD IN NOVICE FEMALE ONE-DAY EVENT RIDERS IS AFFECTED BY ADDITIONAL UN-MOUNTED TRAINING

JOHNSON, J.L.1, PRICE, M.J.2, PETERS, D.M.1,3

1:UW (WORCESTER, UK), 2: CU (COVENTRY, UK), 3: UIA (KRISTIANSAND, NORWAY)

**Introduction** The physical fitness requirements for participation in One Day Eventing (ODE) have received limited investigation (Westerling, 1983; Devienne and Guezennec, 2000; Meyers and Sterling, 2000; Roberts et al., 2009). Extant literature has, however, reported that equestrianism provokes a high aerobic demand, particularly in disciplines where jumping and galloping are involved (Wright and Peters, 2008). Marked blood lactate accumulation reported in equestrian sports where jumping is required also indicates that the anaerobic energy system supports the aerobic system in meeting the metabolic demands of the sport. There is limited research that has identified variables relevant to both maximal and sustained high intensity aerobic exercise in such samples. The aim therefore, was to investigate maximal aerobic power and lactate threshold in novice female ODE riders and identify if the levels required for competition were enhanced by further un-mounted exercise training. **Methods** VO2max and lactate threshold (LT) were determined using a continuous, incremental protocol on a cycle ergometer. Heart Rate (Polar RS800CX Multi, Polar Electro Europe) and blood lactate were recorded. Participants were assigned an additional non-mounted physical training category from interviews as PA1: equitation alone, PA2: moderate additional training and PA3: considerable additional training. Results Mean VO2max was  $41.8 \pm 8.1$  ml.kg<sup>-1</sup>.min<sup>-1</sup>, with a range of 28.5 to 55.7 ml.kg<sup>-1</sup>.min<sup>-1</sup> and mean LT was  $2.8 \pm 0.9$  mMol, with a range of 1.6 to 5.2 mMol. There were differences in VO2max (PA1  $38.0 \pm 7.3$  ml.kg<sup>-1</sup>.min<sup>-1</sup>; PA2  $39.8 \pm 6.2$  ml.kg<sup>-1</sup>.min<sup>-1</sup>; PA3  $51.4 \pm 4.3$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) and Watts at LT (PA1  $110 \pm 13.4$ W; PA2  $130 \pm 20.9$ W; PA3  $163.8 \pm 39.4$ W) between the PA categories ( $p < 0.05$ ). **Discussion** The mean VO2max data would suggest that this sample were at least comparable with or superior in aerobic fitness compared to previous studies. The range identified a wide spectrum of fitness in the novice category and that any fitness enhancement appears due to additional un-mounted training. Combined, the level of aerobic power and LT in the equitation only group (PA1) would suggest that participation in ODE equitation training and competition at this level alone does not result in a high level of aerobic fitness or anaerobic tolerance. ### ANAEROBIC THRESHOLDS FROM T-CAR TEST PREDICT MAXIMAL LACTATE STEADY STATE IN FUTSAL PLAYERS

CARMINATTI, L.J., COSTA, V.P., DITTRICH, N., GUGLIELMO, L.G.A., DE-OLIVEIRA, F.R.

UNIVERSIDADE DO ESTADO DE SANTA CATARINA - UDESC

**Anaerobic thresholds from T-CAR test predict maximal lactate steady state in futsal players** Carminatti, L.J.; Costa, V.P.; Dittrich, N.; Guglielmo, L.G.A.; De-Oliveira, F.R. 1: UFSC / UDESC (Florianópolis, Brazil) 2: UFLA (Lavras, Brazil) **Introduction** Several methods of anaerobic thresholds (AT) determined from continuous incremental tests have been used as predictors of maximal lactate steady state (MLSS): heart rate deflection point by visual method (HRv) (Conconi et al. 1982); mathematical method Dmax (Kara et al. 1996); the predicted Dmax (Dmaxpred) determined by percentage of peak velocity (PV) (80.4%) and HRmax (91.4%) from Carminatti intermittent test (T-CAR) (Carminatti et al. 2005). Thus, the aim of this study was to verify the validity of these AT as predictors of MLSS in futsal players. **Methods** Eight futsal players ( $21.3 \pm 3.1$  years;  $177.4 \pm 7.7$  cm;  $79.4 \pm 21.2$  kg) performed the following field tests: 1) T-CAR to determine AT; PV and HRmax – Field test with multi-stages of 90s in shuttle system (repeated sets of 5 x 12s bouts with pauses of 6s). The initial velocity was set at 9.0 km•h<sup>-1</sup> (controlled by audio beep) with an increase of 0.6 km•h<sup>-1</sup> in each stage until volitional exhaustion; 2) Several constant load test lasting 32min in the T-CAR system (4 x 8min with 1min of pause to collect samples of 25µL of capillary blood) to determine the HR and the velocity at MLSS (HRMLSS and VMLSS). **Results** The blood lactate at MLSS was  $4.2 \pm 1.8$  mmol.l<sup>-1</sup> ( $1.4 - 6.7$  mmol.l<sup>-1</sup>). The HR of the predictors was: HRv ( $186 \pm 11$  bpm); HRDmax ( $178 \pm 10$  bpm) and HRDmaxpred ( $183 \pm 8$  bpm). The velocities were: VHRv ( $13.0 \pm 1.5$  km•h<sup>-1</sup>); VDmax ( $12.2 \pm 1.4$  km•h<sup>-1</sup>) and VDmaxpred ( $12.4 \pm 1.2$  km•h<sup>-1</sup>). The HRMLSS ( $182 \pm 4$  bpm /  $91.2 \pm 3.2$  %HRmax) and VMSS ( $12.5 \pm 1.6$  km•h<sup>-1</sup> /  $81.1 \pm 4.2$  %PV) were not significant different when compared to the several AT predictors ( $p > 0.05$ ). In addition, the correlations between these measures were high and significant: HRv (0.83), HRDmax (0.88), VHRv (0.83), VDmax (0.98) and VDmaxpred (0.91); except for HRDmaxpred (0.53;  $p = 0.176$ ). **Discussion** The blood lactate value at MLSS found in the present study is in agreement to others reported during traditional continuous protocol. The heart rate and the velocities determined by several AT predictors were similar and strongly correlated with HRMLSS and VMLSS, respectively. Therefore, we found evidence of validity of several AT predictors from T-CAR with MLSS in futsal players. References Carminatti L.J., Lima-Silva A.E., De-oliveira F.R. #### PERFORMING SOCCER GAME AFFECTS THE VELOCITY, AGILITY AND PSYCHOPHYSICAL CONDITION IN PSYCHOTIC SUBJECTS

BATTAGLIA, G.2,3, BELLAFFIORE, M.1,2, BIANCO, A.1,2, INGUGLIA, M.3, CARAMAZZA, G.1,2, PALMA, A.1,2

UNIVERSITY OF PALERMO

**Introduction** Physical activity is an important aspect of good health for everyone and is even more important for psychiatric patients who usually live an unhealthy lifestyle and assume medications that tend to reinforce their metabolic syndrome (Kopp, 2009). The purpose of this study was to examine whether performing soccer game by psychotic subjects has effects on their velocity, agility and psychophysical perception. **Methods** Eighteen overweight male subjects, 8 no-trained psychotics (NTPs) (age: 35.00 $\pm$ 5.00 years; height: 163.00 $\pm$ 4.00 cm; BMI: 25.00-29.90) and 10 trained psychotics (TPs) (age: 36.00 $\pm$ 6.00 years; height: 164.00 $\pm$ 7.00 cm; BMI: 25.00-29.90) from Local Health of Palermo (Sicily, Italy) participated in this study. NTPs did not performed any sports activity during the experimentation; while TPs were trained for 8 weeks by two sessions/week. In particular, every trained session included a warm up pattern for 20 minutes (min), a training period of 50 min including soccer technical-tactical exercises and a short match; finally a cool down part for 10 min. We evaluated the physical condition of the subjects measuring their body weight (BW) and body mass index (BMI). The velocity and agility were estimated recording the time used to perform 30 meter sprint test (30mST) and slalom test running with a ball (STB) between 5 cones located 50 cm apart. Psychophysical perception of psychotics was studied using the SF-12 health status questionnaire that measures self-rated health (Faulkner G et al., 2007). It investigated the summary measures PCS-12 (physical domain of SF-12, scores ranging from 0 to 70) and MCS-12 (mental domain of SF-12, scores ranging from 0 to 70). All data were acquired before and after the experimentation. **Results** After the training period PCS-12, MCS-12 and performances of 30mST and STB were improved in TPs compared with NTPs. In contrast, BW and BMI were lower in TPs than NTPs. **Discussion** We showed that training sessions of soccer game can improve the psychophysical condition and sports performance in psychotic subjects. In agreement with Pringle (2009), this might be due to the organized social phenomenon of soccer game that promotes a sporting therapeutic and healthy antagonism. Integrating physical activity programs into psychiatric services can improve physical health outcomes of patients with serious mental illness and may produce improvements in psychological and social outcomes. **References** Kopp M: Physical activity in persons with severe mental illness: research-based clinical recommendations. *Neuropsychiatr*. 2009; 23(3):151-6. #### PHYSIOLOGICAL DEMANDS OF TURN MOVEMENTS AT DIFFERENT RUNNING SPEEDS

HATAMOTO, Y., YAMADA, Y., HATANAKA, T., HIGAKI, Y., KIYONAGA, A., TANAKA, H.

FUKUOKA UNIVERSITY

**Introduction** Turn movements are essential to evade or pursue an opponent in ball sports. Bloomfield et al. (2007) reported there were about 5,000 turn movements in an English Premier League soccer match. It is important to know the total energy expenditure (EE) of players in a match to determine an appropriate diet (Alberto et al 2008). The EE of turn movements contributes to the total EE during a soccer match. Although many previous biomechanics studies have been published regarding turn movements, research describing the physiological demands of turn movements is sparse. The aim of the present study was to investigate the effects of running speed on EE for a 180° turn using the "different frequency accumulation method". **Methods** Seven healthy young men participated in eight running sets at a constant speed. Each set was 5 minutes in duration. The participants turned 180° repetitively during the 5-minute running interval. The EE during running and turning was measured using a portable metabolic system (Meta Max 3B). Subjects ran at speeds of 75, 100, 125, and 150 m/min with turn frequencies of 10 and 20 turns/min for each speed. We calculated the EE of a turn at each speed from the slope of regression for EE against turn frequencies. After each set, ratings of perceived exertion (RPE) were surveyed using the Borg scale. **Results** The EE of a turn at 75, 100, 125, and 150 m/min was 5.9  $\pm$  2.2, 12.3  $\pm$  2.3, 18.7  $\pm$  6.6, and 24.7  $\pm$  8.3 J/kg, respectively. As the running speed increased, the EE of a turn increased. The correlation coefficient between the EE of a turn and running speeds was strong (mean  $r$  = 0.99), and the relationship appeared to be linear. At a speed of 150 m/min running with 20 turns/min, the RPE was very high (18.1  $\pm$  0.7). **Conclusion** In this study, we examined whether the EE of a turn movement was affected by running speed. The strong correlation between the EE of a 180° turn and running speed implies that the EE of a 180° turn can be calculated from running speed. The results of the present study indicate that as running speed increases, the energy consumption of a turn during running increases in a linear manner, and RPE is increased when the turn frequency is increased. **References** Bloomfield, J. et al. *Journal of Sports Science and Medicine* (2007), Suppl. 10, 9-10. #### GENETIC DIVERSITY OF LITHUANIAN FOOTBALL PLAYERS ACCORDING TO THE POSITION OF PLAY ON THE FIELD

GINEVIČIENĖ, V.1,2, JAKAITIENĖ, A.1, MILAŠIUS, K.3, TUBELIS, L.2, KUČINSKAS, V.1

1VILNIUS UNIVERSITY, 2LITHUANIAN OLYMPIC SPORTS CENTRE, 3VILNIUS PEDAGOGICAL UNIVERSITY, LITHUANIA

**Introduction** Football is the most popular sport in the world. Our hypothesis is that genetic information might significantly influence a footballer's career. The purpose of this study was to assess the ACE I/D, PPARGC1A G/A and PPARA G/C polymorphisms' genotype and allele frequency distributions in Lithuanian football player groups. **Methods** The study involved 400 footballers (81 forwards, 124 defenders, 35 goalkeepers, 160 midfielders) and 167 controls (male non-athletes from the general Lithuanian population). Genotyping was performed by PCR-RFLP. Genotype and allele frequency differences between the groups were assessed by the chi-squared test with the expected values equal for all categories. **Results** Hardy-Weinberg equilibrium calculations of ACE, PPARGC1A and PPARA genotypes frequencies showed no deviation from expected frequencies in the Lithuanian footballers group. ACE I/D genotype frequencies of the footballers were different from those of the controls (II/ID/DD:24.0/46.5/29.5% vs. 24.6/29.9/45.5%;  $p$ <0.05). ACE D/D genotype and D allele were significantly less common among football players compared to controls ( $p$ <0.05). For the goalkeepers the ACE I allele (51.4%) was more frequent when compared to other football players (defenders-48.4%; midfielders-48.1%; forwards-42.0%) and controls (39.5%). We found no significant PPARGC1A G/A polymorphism genotype frequency differences between the footballers and controls

(GG/GA/AA:50.2/41.0/8.8% vs. 49.7/44.3/6.0%;  $p>0.05$ ). The frequency of the PPARGC1A G allele was higher for the midfielders (72.2%) and goalkeepers (75.7%) compared to the forwards (69.1%), defenders (68.5%) and controls (71.9%). Similarly for the PPARGC1A G/C polymorphism the footballers were not significantly different from controls (GG/GC/CC:67.5/29.5/3.0% vs. 72.5/24.5/3.0%;  $p>0.05$ ). The PPARGC1A C allele was slightly more common among the forwards (22.8%) compared to other footballers (goalkeepers-12.9%, defenders-16.5%, midfielders -17.2%) and controls (15.3%). However the PPARGC1A G allele had higher frequency among the goalkeepers (87.1%) compared to other footballers (forwards-77.2%, defenders-83.5%, midfielders-82.8%) and controls (84.7%). There were no PPARGC1A A/A or PPARGC1A C/C genotype athletes among the researched goalkeepers. Discussion It has been determined by other researchers that ACE I, PPARGC1A G and PPARGC1A A alleles enhance aerobic endurance while the ACE D, PPARGC1A A, and PPARGC1A C alleles are associated with speed and power. Our study shows that according to the ACE I/D, PPARGC1A G/A and PPARGC1A G/C polymorphisms footballers have mixed (speed/power and endurance) genotype combinations. These findings support our theory that footballers require both aerobic and anaerobic energy system balance as well as the stability of the regulatory mechanisms to be success in their sport.

### TEMPORAL PATTERNS ANALYSIS IN THE GOALS SCORED BY FOOTBALL TEAMS

SARMENTO, H.1,2,4, MARTINS, N.1,2, MARTINS, J.3, MARQUES, A.3, BARBOSA, A.1,2, ANGUERA, T.2,3, CAMPANIÇO, J.1,2, LEITÃO, J.1,2

1-UTAD, VILA REAL, PORTUGAL 2-CIDESD, PORTUGAL 3-FMH, LISBOA, PORTUGAL 4-UB, BARCELONA, ESPANHA

Introduction Studies that focus on simple frequency analysis cannot identify temporal patterns within a sport performance. The purpose of this study was to detect patterns of behavior, known as T-pattern (characterized by their temporal and sequential structure), in the goals scored by the teams of F.C. Internazionale Milano (IM), F. C. Barcelona (FCB), and Manchester United (MU) in the 2009/2010 sporting season. Methods Sixty-one goals (24 scored by FCB, 17 by IM and 21 by MU), resulting from thirty-six games (12 per team), were encoded using the observational instrument developed by Sarmento et al. (2010). The reliability of the data was calculated by the intraobserver agreement, and values above 0.95 for all criteria were achieved. For the detection of temporal patterns, we used the software THÈME 5.0., and the following criteria were used: the minimum number of events was set at 3 and the level of significance was set at 0.005. Results and Discussion In relation to the goals scored by FCB, we detected 578 T-patterns, of which 12 were complete patterns, because they contained all the codes present in the observational instrument, since the start until the end of the OP. The completed t-patterns found provide important information about the regularities of all game actions and the interactions that occur between players in the different phases of the OP. These regularities have a sequential structure that is repeated with the same interval of time in three different offensive sequences. For the IM and MU teams, we found 18 and 9 T-patterns, respectively. None of these T-patterns was complete, but the incomplete t-patterns detected provide important information about how the offensive sequences that end in a goal begin and develop. The more significant T-patterns will be later explained in a detailed way. Conclusion The detection of behavior patterns in offensive plays (T-patterns) proves to be particularly interesting. The number of detected T-patterns indicates that the structure of the game is much more complex than the "human eye" can detect. The difference of patterns found between these different teams, suggest that the FCB offensive sequences are more consistent in their temporal structure than those of other teams. This type of analysis provides important information for coaches that can be used in the training process. Sarmento, H., Anguera, T., Campaniço, J., & Leitão, J. (2010). Development and Validation of a Notational System to Study the Offensive Process in Football. *Medicina (Kaunas)*, 46(6), 401-407.

### DEVELOPMENT OF AN EXERCISE PROTOCOL THAT SIMULATES THE ACTIVITY PATTERN OF INTERNATIONAL TAEKWONDO COMPETITION

BRIDGE, C.A.1, DRUST, B.2

1 EDGE HILL UNIVERSITY, UK; 2 LIVERPOOL JOHN MOORES UNIVERSITY, UK

Introduction Exercise protocols that simulate the activity pattern of competition have been devised for various sports. These simulations provide an ergonomic framework to permit more detailed examinations of the physiological responses to specific intermittent activity patterns. They also offer a controlled model to facilitate the study of interventions (Drust et al. 2007). The aim of this study was to devise an exercise protocol that serves to replicate the activity profile of international Taekwondo competition. Methods The exercise protocol devised in this study was modelled on the time-motion data obtained from international Taekwondo competition (Bridge et al. 2011). The regular fighting, preparatory, non-preparatory, and stoppage activity phases performed in competition formed the fundamental framework of the protocol. These activity phases were arranged into 36 individual cycles of movement. Each individual cycle of movement required the participants to perform either a single non-preparatory or stoppage activity phase followed by a preparatory and fighting activity phase. Each activity phase contained a collection of Taekwondo actions that were arranged into irregular sequences. The individual cycles of movement were assembled to formulate three two-minute blocks of exercise. A one minute rest interval separated each block of exercise. This configuration represented the three two-minute rounds of international combat. Eight male Taekwondo competitors performed each predetermined cycle of movement on a specifically design 1.7 m course and stationary kick bag. These actions were performed in time with an audio signal that provided specific activity instructions. Results The mean fighting time set in the exercise protocol was 1.3 s, preparatory time 7.0 s, non-preparatory time 4.0 s, stoppage time 1.6 s, fighting to non-fighting ratio (1:x) 6.0 and 32 exchanges and 35 kicks were included. These compare favourably with the mean  $\pm$  SD range of time-motion data measured in international Taekwondo competition. The mean  $\pm$  SD fighting time in the international competition was  $1.7 \pm 0.4$  s, preparatory time  $6.4 \pm 2.1$  s, non-preparatory time  $3.0 \pm 0.6$  s, stoppage time  $2.8 \pm 0.9$  s, fighting to non-fighting ratio (1:x)  $6.3 \pm 2.0$  and  $28 \pm 6$  exchanges and  $31 \pm 7$  kicks were performed. Conclusions The exercise protocol devised in this study provides a reasonable approximation of the activity pattern performed in international Taekwondo competition. This protocol may therefore serve as useful ergonomic model to permit more detailed study of the physiological responses to Taekwondo-specific intermittent exercise. References Bridge C.A. et al. ### TIME-MOTION ANALYSIS OF ELITE HURLING MATCH-PLAY

COLLINS, K.1, DORAN, D.A.2, MCROBERT, A.P.2, MORTON, J.2, REILLY, T.P.2

1: ITTD (DUBLIN, IRELAND) 2: LJMU (LIVERPOOL, ENGLAND)

Introduction Time-motion analysis is a useful method for quantifying the work-rate of a sport and provides a conceptual framework for the development and prescription of specific training regimes. Therefore, the aims of the present study were two-fold, first to quantify the type and frequency of movement activity displayed by elite hurling players in competition and second, to examine the occurrence of high-

intensity activity during elite match-play to provide an insight into any fatigue related changes in performance. Methods Fifteen, male (age:  $27 \pm 4$  years) outfield hurling players (six defenders, three midfielders and six forwards) participating in the knock out stages of the All-Ireland hurling championships were video recorded throughout an entire game (70 mins). One camera was used per player to follow each of the players throughout the game. The camera was positioned above the half-way line to enable the players to be clearly monitored irrespective of position on the field of play. The player's activities were coded (SportsCode, Warriewood, NSW, Australia) into one of seven movement categories: stationary, walking, shuffling, cruising, run/sprint, backward motion and sideways movement. For each activity, the frequency, mean duration and percentage of total time were calculated. Activity was further classified as low-intensity (stationary, walking, shuffling, backward and sideways movement) or high-intensity (cruising, run/sprint). Data were analysed using a one-way analysis of variance and are presented as means and standard deviations. Statistical significance was set at  $p < 0.05$ . Utilizing Cohen's kappa the intra-observer reliability never exceeded 2.1% for the activity categories. Results Participants spent  $6.6 \pm 2.6\%$  of total match time standing stationary,  $43.8 \pm 4.3\%$  walking,  $14.8 \pm 4.4\%$  shuffling,  $9 \pm 2.8\%$  jogging,  $7.3 \pm 2.5\%$  run/sprint,  $3.3 \pm 0.8\%$  in sideways movement and  $15.1 \pm 2.5\%$  in backwards movement. On average, there was a transition every 3.7 sec between different activities. Of these transitions, the ratio between high-intensity activities to low-intensity activities was approximately 1:5.3. No significant difference in the percentage time spent performing low-intensity and high-intensity activity between the 1st and 2nd half was observed. Discussion Involvement in elite hurling requires intermittent bouts of complex high-intensity movement patterns interspersed with periods of low-intensity activity. These initial findings indicate that any field based fitness tests or training programmes devised should be both multi-modal and intermittent in nature to simulate the demands of match-play. The current data represent a valuable contemporary characterization of the activity profiles of hurling players and will be of interest to elite level coaches. References

### GAME DEMANDS IN ELITE FEMALE RUGBY SEVENS

SUÁREZ-ARRONES, L., NUÑEZ, J., PORTILLO, J., MOLANO, F., MENDEZ-VILLANUEVA, A.

PABLO DE OLAVIDE UNIVERSITY

GAME DEMANDS IN ELITE FEMALE RUGBY SEVENS Suarez, L.1,2; Nuñez, J.1,2; Portillo, J.3 Molano, F.1,2 and Mendez-Villanueva, A.4. 1:UPO (Sevilla, Spain), 2:VFsport (Sevilla, Spain), 3:UCLM (Toledo, Spain), 4:Physiology Unit, ASPIRE, Academy for Sports Excellence (Doha, Qatar) INTRODUCTION Rugby Sevens was recently voted one of the new summer Olympic sports and will appear for the first time in the 2016 Olympic Games in Rio de Janeiro. While several studies have investigated the match play demands of rugby union to our knowledge no previous study has described the match activity profiles of female Rugby Sevens players. The purpose of the present study was to describe the match-play demands of professional female rugby players competing in Rugby Sevens matches. METHODS Time-motion analysis of running activity was performed on 12 elite female rugby players belonging to the same national team during 5 competitive matches in a 2-day international tournament. Portable global position system (GPS, 1Hz SPI Elite, GPSports, Canberra, Australia) technology and heart rate (HR) responses were used to assess match running demands and exercise intensity, respectively. RESULTS Mean total distance ( $\pm$  SD) covered over the whole match by all players was  $1556.2 \pm 189.3$  m. Low-intensity activities represented 62.9 % of total time, which consisted of 29.7% ( $462.6 \pm 94.6$  m) standing and walking and 33.2% ( $515.9 \pm 88.6$  m) jogging. Cruising, striding, high-intensity running and sprinting represented 11.6% ( $181 \pm 61.4$  m), 16.4% ( $255.7 \pm 88.3$  m), 3.7% ( $57.1 \pm 40.8$  m) and 5.4% ( $84.0 \pm 64.8$  m) of total time, respectively. The average maximal distance of sprints, number of sprints, minimum distance of sprint and mean sprint distance over the game were:  $25.8 \pm 16.1$  m,  $5.3 \pm 3.2$  sprints,  $6.5 \pm 2.0$  m, and  $17.2 \pm 8.8$  m, respectively. For over 75% of the game, players were exposed to heart rates above 80% of their maximal heart rate. DISCUSSION It has been previously reported that male rugby union (15-a side) players covered a total match distance ranging from 5408 to 6953 m (Cunniffe et al., 2009; King et al., 2009; Roberts et al., 2008). Extrapolating the women rugby 7's playing time to the 15-a side male rugby match duration ( $\sim 83$  min) (Cunniffe et al., 2009) the resulting figure would be a game coverage of  $\sim 8950$  m. Thus, overall running demands appear to be much higher in female rugby 7's than in the male a-15 rugby code. Collectively, these findings provide important information for prescription of training aimed at developing physiological qualities specific to the demands of competitive elite female rugby 7's. ### COMPARISON OF MOVEMENTS DEMANDS OF MATCH PLAY AND TRAINING IN ELITE AUSTRALIAN FOOTBALL

COUTTS, A.J.1,2, BILSBOROUGH, J.B.1,2, HUNTER, M.2, ROSSIANI, D.1,2, CORDY, J.2

1: UTS (SYDNEY, AUSTRALIA), 2: CARLTON FOOTBALL CLUB (MELBOURNE, AUSTRALIA)

Introduction Specific training is important for preparing team sport athletes for competition, however, it is unknown if the training reflects current match demands in professional Australian Football (AF). One previous study has shown that during training, AF players spend a greater proportion of time standing, less time running, have similar high-intensity efforts and greater involvement with the ball compared to match play [1]. However since this study was completed, the match demands of professional AF have increased [2]. It is not known if current training practices reflect these increased match demands. Therefore, the purpose of this study was to compare the movement demands of match play and training in a professional AF club. Methods Twenty eight professional AF players (mean $\pm$ SD) age:  $23 \pm 3$  yr) from the same club participated in this study. Data was collected from 14 official AFL matches (132 files) and 70 skill-based training sessions (572 files) during the 2010 season. Player movement was quantified using 5-Hz GPS (MinimaxX, Catapult Innovations) and analysed for mean exercise intensity (m/min), high intensity running (HIR/min:  $>14$  km/h), and very high intensity running (VHIR/min:  $>23$ km/h). Training activities were classified as Kicking, Handball, Ball movement, Game sense, Defensive actions, Positional skill/strategy, and Skill acquisition drills. All training data was coded real-time for separate drills and analysed post hoc using proprietary software. Results The mean exercise intensity during match-play was  $129 \pm 9$  m/min,  $40 \pm 9$  HIR m/min and  $6 \pm 3$  VHIR m/min, respectively. The movement demands of the training sessions were lower than matches and had greater variability (games 9% vs. training sessions 42%). The most demanding training drills were Games Sense Drills ( $129 \pm 35$  m/min,  $24 \pm 13$  HIR m/min and VHIR  $12 \pm 7$  m/min), whilst Positional skill/strategy drills had the lowest movement demands ( $66 \pm 22$  m/min,  $7 \pm 5$  HIR/min and VHIR  $4 \pm 4$  m/min). 72.8%, 17.2% and 9.8% of training drills were lower, similar to, and greater than mean match intensity, respectively. Discussion In agreement with previous research [1], these findings show that most training drills completed by professional AF players were lower than typical match demands and have higher variability. The lower intensities in training drills was most likely due to the time spent coaching and/or the need to develop new technical/tactical abilities at these lower intensities. Coaches can use the present findings to prepare specific training sessions and better control the training process in professional AF. References 1. ## THE TECHNICAL PERFORMANCE OF TOP LEVEL SOCCER GOALKEEPERS DURING THE FIFA WORLD CUP 2010.

DE PAOLA, M.1, D'ARTIBALE, E.1, CALCAGNO, G.1, DI CAGNO, A.1

UNIVERSITY OF MOLISE

**Introduction** In respect to other field positions, the individual goalkeeper's actions could have a key role in the match's final result. The goalkeeper's performance in soccer, can be associated with two main actions: positioning choices and defense technique selection. The aim of this study was to obtain detailed information about the technical actions and the performance of the top-level goalkeepers. The final purpose was to obtain information in order to organize and design specific training, which would simulate realistic game-like situations. Methods 17 goalkeepers playing in the last 16 matches in the FIFA World Cup 2010 were analyzed with recorded video. The goalkeepers' actions were divided in save (S) if the ball was directed towards the goal, and coming out (CO) if the ball was intercepted or not directed towards the goal. Each action was labelled: hand high (HH), hand low (HL), feet high (FH), feet low (FL). For ball and goalkeeper positions data, the goal was divided in eight rectangles (1.83x1.22mt), the goal area in ten squares (1.83x1.83mt) and the penalty area in five rectangles. Descriptive and statistical analysis were applied. Results 398 total actions (n°276 CO; n°122 S) were recorded (on average n°12.4 actions for each goalkeeper for each match). Saves were n°46 (37.7%) HH; n°66 (54.1%) HL; none FH and n°10 (8.2%) FL. Higher quantities for CO actions: n°135 (48.9%) HH; n°110 (39.9%) HL; n°1 (0.4%) FH and n°30 (10.9%) FL. Goalkeepers suffered 42 goals and in 28.6% of the cases they were positioned outside the goal area. The highest number of goals (n°11) was scored in the left-side-low-corner portion of the goal; and the highest quantity of saves (n°46) happened in the middle of the goal just in front of the goal line. Discussion This study attempted to understand those aspects related to the optimization of soccer goalkeepers' resources and to clarify competition demands. From those findings, goalkeeper performance appears to be particularly interested in catching every ball circulating in the goal zone (goal area or penalty area). This behaviour could enlighten the importance of coming out that represents an excellent solution for team ball possession. Therefore, goalkeepers should be trained with particular attention to catch the ball, also if it is not directed towards the goal, as well as to be able to move fast in short distances. When inside the goal, they should be trained to perform both low and angular saves. References Lamas, Ugrinowitsch, Barrera, (2010). ## QUANTIFYING THE GAP BETWEEN UNDER 18 AND SENIOR AFL FOOTBALL: 2003-2009

BURGESS, D., NAUGHTON, G., NORTON, K.

LIVERPOOL FOOTBALL CLUB

**Purpose** A successful transition from elite Under 18 Australian Rules (U18) teams to professional senior competition depends on synergies among physical, tactical, psychological and maturational factors. The increasing use of notational analysis may assist in quantifying the demands of these two different levels of competition. No studies have compared individual players' movement rate, game statistics and ball speed in U18 and senior competition of the Australian Football League across time. This project compared differences in player movement and ball speed between matches from senior AFL competitive matches and U18 players in the 2003 and 2009 seasons. Methods TrakPerformance Software and Global Positioning System (GPS) technology were used to analyse the movement of players, ball speed and game statistics. Analysis of variance (ANOVA) compared the two levels of competition over time. Results Observed interactions for distance travelled per minute of play ( $p = 0.009$ ), number of sprints per minute of play ( $p < 0.001$ ), time spent at sprint speed in the game ( $p < 0.001$ ), time on field ( $p < 0.001$ ), and ball speed ( $p < 0.001$ ) were found. Subsequent analysis identified increases in movement patterns in senior AFL competition in 2009 compared with the same level of competition in 2003 and U18 players in 2003 and 2009. Conclusions Senior AFL players in 2009 were moving further, sprinting relatively more frequently, playing less time and playing at game speeds significantly greater than the same senior competition in 2003 as well as compared with both cohorts of U18 players.

## THE EFFECT OF RAPID DIRECTIONAL CHANGES ON GPS VALIDITY DURING INTERMITTENT HIGH-INTENSITY ACTIVITY

RAWSTORN, J., MADDISON, R., GANT, N.

THE UNIVERSITY OF AUCKLAND

**Purpose** Use of the Global Positioning System (GPS) for quantifying the movement demands of high intensity multi-directional activities is increasing. However, GPS device measurement validity has not been assessed using well-validated protocols that incorporate the frequent, rapid changes in direction encountered during intermittent team sports. This study aimed to evaluate the distance measurement precision and reliability of three GPS devices by contrasting protocols with identical speed profiles but dissimilar directional requirements. Method Team sport athletes completed two 90 min trials of the Loughborough Intermittent Shuttle Test activity pattern (Nicholas et al., 2000). One was completed on a 20 m shuttle running track (LIN), the other on a 200 m curvilinear running track (CUR). Distance measured by three GPS devices (position sampling frequency; Device A = 15Hz, Device B = 1Hz, Device C = 1Hz) was assessed for systematic measurement bias, absolute and relative reliability, and epoch error. Results GPS and criterion distance measures differed during both protocols in all devices (all  $p < 0.001$ ). Each device underestimated distance for LIN (relative distance =  $96 \pm 3\%$ ,  $91 \pm 2\%$  and  $50 \pm 1\%$ , for Devices A, B and C respectively) but not for CUR (relative distance =  $103 \pm 1\%$ ,  $104 \pm 2\%$  and  $99 \pm 4\%$ , for Devices A, B and C respectively). Absolute measurement reliability during LIN and CUR protocols was superior for Device A (CV = LIN 2.44%, CUR 2.16%; LOA = LIN  $\pm 453.4\text{m}$ , CUR  $\pm 223.2\text{m}$ ) compared with B (CV = LIN 7.52% CUR 2.65%, LOA = LIN  $\pm 742.7\text{m}$  CUR  $\pm 384.2\text{m}$ ), and C (CV = LIN 46.12% CUR 3.55%, LOA = LIN  $\pm 3474.8\text{m}$  CUR  $\pm 820.4$ ). Conclusion This study shows that rapid directional changes reduce GPS distance measurement validity. Complex multi-directional movement patterns that involve stop-start activities increase within-epoch divergence of scalar and vector movement quantities. The superior measurement validity provided by Device A supports this notion, as the greater measurement resolution provided by a 15Hz position sampling frequency reduced the within-epoch separation of actual device displacement and output distance measures. Therefore it may be inappropriate to use low sampling frequency GPS devices to quantify the movement demands of intermittent team sport and multi-directional physical activity. References Nicholas, C.W., Nuttall, F.E., & Williams, C. (2000). The Loughborough Intermittent Shuttle Test: a field test that simulates the activity pattern of soccer. **PHYSICAL AND PHYSIOLOGICAL PROFILES OF TURKISH AMPUTEE FOOTBALL REFEREES**

ASLAN, C.S.1, ARAS, D.1, EYUBOGLU, E.1, OZDEMIR, F.N.1, AKALAN, C.1, BALCI, V.1, SUNAY, H.1

ANKARA UNIVERSITY THE SCHOOL OF PHYSICAL EDUCATION &amp; SPORTS

Introduction Amputee football is a kind of football whose players are one leg amputees. Although, "activity profiles and physical requirements of soccer referees (SR) have been examined in number of studies" (Krustrup et al, 2009), research for amputee football referees (AFR) were limited. For that reason of limited studies about AFR, this study aim to determined physical and physiological profiles of Turkish AFR. Methods There were 27 Turkish AFR participated to study. Age, height, body weight (BW), somatotype, body fat percentage (BFP), soft lean mass (SLM), flexibility (F), vertical jump (VJ), leg strength (LS) and anaerobic power (ANP) characteristics were determined. VO2max was estimated with BFP formula belonged Wier et al (2006). Descriptive statistic determined by SPSS (ver.13). Results Age of AFR was found  $33,81 \pm 8,50$  years, height  $176,83 \pm 6,33$  cm, BW  $77,77 \pm 10,68$  kg, BMI  $24,93 \pm 2,98$  kg/m<sup>2</sup>, endomorphy  $3,53 \pm 3,32$ , mezomorphy  $4,48 \pm 1,48$ , ectomorphy  $2,18 \pm 1,39$ , BFP  $21,16 \pm 5,57$  %, SLM  $56,43 \pm 5,67$  kg, F  $22,56 \pm 7,92$ cm, VJ  $50,93 \pm 6,09$  cm, LS  $154,46 \pm 21,80$  kg, ANP  $87,57 \pm 15,97$  kgm/sec, VO2max  $43,91 \pm 4,87$  ml/kg-min. Discussion It was not found any study about physical and physiological characteristics of AFR for that reason result of this study was compared with soccer referees. Although Kızılet et al (2010)'s study with Turkish elite SR and Casajus and Castagna (2007)'s study with Spanish elite SR' mean age, height and BW were similar of AFR but BFP of AFR were higher than elite SR. Additionally AFR have higher BFP and similar F and VO2max capacities when compared to Pulur and Yamaner (2004)'s study with lower level Turkish SR. **Poster presentations****PP-PM72 Swimming Related Activity****TECHNICAL VARIABLES, STROKE PHASES AND INDEX OF COORDINATION AT AND ABOVE THE INTERMITTENT MAXIMAL LACTATE STEADY STATE IN SWIMMING**

PELARIGO, J.G.1,2, DENADAI, B.S.1, GRECO, C.C.1

FACULTY OF SPORT - UNIVERSITY OF PORTO 1: SÃO PAULO STATE UNIVERSITY, BRAZIL, 2: CIFI2D, FACULTY OF SPORT, UNIVERSITY OF PORTO, PORTO, PORTUGAL.

Introduction In swimming, the prescription of aerobic training, even in long-distance athletes, is done mostly on an intermittent basis, which allows them to be made proportionately greater in intensity than if performed continuously (Maglisho, 1993). This improves performance in intermittent exercise has been attributed to factors such as the removal of lactate (passive and active recovery) and restoration of creatine phosphate (passive recovery). Thereby, the aim of this study was to analyze changes in stroke parameters (i.e., stroke length - SL and stroke rate - SR) and arm coordination (i.e., propulsive and non-propulsive phases and index of coordination - IdC) when swimming at (100%) and above (102.5%) intermittent maximal lactate steady state (MLSSI). Methods Nine male endurance swimmers ( $18.56 \pm 2.13$  yr;  $68.06 \pm 6.48$  kg;  $1.76 \pm 0.64$  m) performed in different days two to four tests of 12 repetitions of 150 s with 30 s (relation effort/rest 5:1) of passive recovery between repetitions to determine the MLSSI, with 2.5% at difference between velocities (Pelarigo et al., 2010). Video analysis was used to determine the SR, SL, stroke phases and IdC. The IdC was determined using the lag times between the propulsive phases of each arm (Chollet et al., 2000). Blood lactate and stroke technique variables were analyzed at 10th and 30th minute swim of each imposed speed test. Results There was significant difference between MLSSI ( $1.26 \pm 0.06$  m.s<sup>-1</sup>) and 102.5% MLSSI ( $1.29 \pm 0.06$  m.s<sup>-1</sup>). SR and SL maintained between the 10th and 30th minute of the test swim have modified significantly at 102.5% MLSSI (SR -  $32.66 \pm 3.42$  and  $33.85 \pm 2.84$  cycles.min<sup>-1</sup> and SL -  $2.40 \pm 0.24$  and  $2.30 \pm 0.17$  m.cycle<sup>-1</sup>, respectively), but there wasn't significant difference between MLSSI. In relation the time effect, all stroke phases maintained at 10th and 30th minute at MLSSI, however, the propulsive phase B increased significantly at 102.5% MLSSI ( $23.0 \pm 3.5$  and  $24.3 \pm 3.3$ %, respectively). In relation the intensity effect (MLSSI and 102.5% MLSSI), there was significant difference in Phase A at 10th and 30th minute ( $38.3 \pm 5.9$  and  $35.5 \pm 6.8$  and  $39.0 \pm 4.9$  and  $34.5 \pm 5.7$ %), in Phase B at 30th minute ( $21.7 \pm 2.8$  and  $24.3 \pm 3.3$ %) and in Phase C at 10th and 30th minute ( $23.0 \pm 2.3$  and  $25.1 \pm 2.7$  and  $23.3 \pm 2.3$  and  $24.8 \pm 2.6$ %), respectively. Conclusions Therefore, the intermittent exercise and the metabolic condition seem influence the stroke parameters (SR and SL) and stroke strategy to maintain the speed during swim intermittent tests lasting 30 min. **FIRST SHOOTING CHOICE AND FINAL EXECUTION IN WATER POLO PENALTY**

PAPAMARGARITIS, TH., PLATANOU, T.

KAPODISTRIAN UNIVERSITY OF ATHENS

FIRST SHOOTING CHOICE AND FINAL EXECUTION IN WATER POLO PENALTY Papamargaritis, Th., Platanou, T. Department of Aquatic Sports, Faculty of Physical Education and Sport Science, University of Athens Greece Introduction Penalty is a very difficult situation for water polo goalkeepers as it is for all the goalkeepers of the other team sports in which this regulation applies. They have to face the opponent shooter without the aid of another defender player. An important factor for the goalkeeper to avert a goal is his ability to know the direction that he has to move in a relation to the angle chosen by the shooter. This must happened before the implementation of the shootout. The question is if the shooter changes the first decision about where he will direct the ball the time when the ball leaves from his hands. The purpose of the study was to examine whether the angle chosen by the shooter during the execution of penalty, when he is positioned at the penalty spot, coincides with the final angle shoot after the referee's signal. Methods For the purpose of the research took

part 18 water polo players who had at least 10 years' experience in this sport. All the participants were asked to shoot 5 penalties. When the player was positioned at the penalty spot, he informed the researcher about the angle he chooses to shoot. The researcher and the shooter were communicated by using two mobile phones. One of them was connected with a waterproof Bluetooth on shooter's ear. The researcher had the other mobile. Then, the players executed the penalty but they had the choice to change their first decision and shoot to another angle. The researcher noted the default angle that shooter had previously chosen and also he noted the final angle that the shooter directed the ball. All the instructions were given without the presence of the goalkeeper. Goalkeeper was given the direction to make any effort in order to save the goal. Finally, we measured the number of shoots which were executed to the same angle and those which were changed angle and we also measured the percentage relative to the total number of each case. Results Of the total 90 penalty which were executed by the 18 water polo players the 72 penalties (80%) were directed to the angle that the shooters had already chosen to shoot. 12 penalties (13, 3%) were directed at a different angle of this, that they first chose but in the same side of the terminal and 6 penalties (6,7%) were directed at a different side and angle of the terminal. Discussion The initial choice of the angle that the shooter aims to shoot the penalty rarely changes. Therefore, the predictability of goalkeeper to move in the right direction that the shooter has chosen before can avert the goal. Goalkeeper's predictability, in order to move in the right direction that shooter has already picked to shoot can finally avert the goal.

## VISUAL FEEDBACK AND MOTOR CONTROL IN SWIMMING AND WALKING

INVERNIZZI, P., SCURATI, R., LONGO, S., MICHIELON, G.

UNIVERSITÀ DEGLI STUDI DI MILANO

Introduction In swimming, sensory-perception is strictly related to the so called "feel of the water" and to the ability in reducing the drag forces. Anyway the visual feedback, that has a basic role in the motor control and learning and that supports the swimmers in displacements along a straight direction when they swim in a lane, does not attend so easily in open water events. This study aimed to analyze the consequences of a visual deprivation both in walking exercise and in swimming. Methods 20 young swimmers, aged 8 to 11 years, participated to the study. After a familiarization to perform the trials at low to middle intensity, subjects underwent three tests both in visual feedback (VF) and in visual deprivation (VD) conditions: 25m front crawl and 25m backstroke in a double-wide lane set; 25m walking along a line in a gymnasium set. They were surveyed: i) stroke length (SL) and stroke rate in the first 10m of the swim tests (i.e. until no deviations were detected); ii) amplitude (PA) and frequency of the path in the first 10m of the walking test; iii) velocity (v) in the first 10m; iv) deviations of displacements from the straight direction; v) limbs dominance, vi) side of breathing in the 25m crawl. Results SL and PA significantly lowered ( $p < 0.05$ ) in VD (SL crawl:  $1.8 \pm 0.27$  vs  $0.97 \pm 0.26$ , m/stroke; SL backstroke:  $1.41 \pm 0.37$  vs  $1.16 \pm 0.25$ , m/stroke; PA:  $1.16 \pm 0.19$  vs  $0.76 \pm 0.17$ , m; VF vs VD, respectively). In VD the velocities also decreased (Crawl: from  $0.87 \pm 0.09$  to  $0.76 \pm 0.22$ , m/s; Backstroke: from  $0.87 \pm 0.17$  to  $0.75 \pm 0.16$ , m/s; Walking: from  $0.93 \pm 0.21$  to  $0.70 \pm 0.19$ , m/s; VF vs VD, respectively). Furthermore, subjects showed significant correlations between the side of the deviation and: 1) the side of breathing in the 25m crawl ( $p < 0.01$ ); 2) the lower limb dominance ( $p < 0.01$ ). Discussion There is evidence that visual deprivation significantly decreased the velocity of the displacements, both in swimming and in walking. The main effect of this deceleration is that the amplitude of SL and PA (i.e. the cinematic variables most related to the motor control and to the technical skills management) shortened. Visual deprivation probably induced subjects to displace more carefully, dropping the intensity of the actions in both the environments. The correlations between the side of the deviations and either the side of breathing in the 25m crawl and the lower limb dominance show that symmetry of the actions highly affects the spatial guidance. It can be concluded that in young swimmers, even in a simple task such as displacing at low to middle velocity for short distance, visual deprivation significantly modifies the output of the movements. ## GENDER, BLOOD LACTATE RESPONSE, BODY FAT AND AEROBIC PERFORMANCE IN SWIMMING.

PELARIGO, J.G.1,2, DENADAI, B.S.1, GRECO, C.C.1

FACULTY OF SPORT - UNIVERSITY OF PORTO

Introduction The performance in swimming, as in other cyclic sports such cycling and running, has been linked strongly to physiological, technical and physical capacities. But, as water locomotion demands more energy per unit distance than locomotion on land (Pendergast et al., 2003), the control of technical level may be important to increase propulsive force and reduce active drag (Kolmogorov & Duplischeva, 1992). Thus, the objective of this study was to verify the effect of gender on blood lactate response ([La]) and body fat percentage (%BF) in the relationship between anaerobic threshold (AnT) and maximal speed of 30 min (S30) in swimming. Methods Twenty-one male and thirteen females swimmers (age =  $15.35 \pm 2.18$  and  $15.33 \pm 1.56$  yr; bodyweight =  $63.40 \pm 12.61$  and  $57.32 \pm 9.64$  kg; stature =  $1.72 \pm 0.91$  and  $1.65 \pm 0.60$  m, respectively) with at least five years of experience in swimming were divided in male and female groups (GM and GF), respectively. GM and GF had similar aerobic performance levels (S30). S30 was determined through a maximal 30 min test, recording the distance in meters, calculating velocity by dividing the distance by time. Blood lactate was analyzed at 10th and 30th minute swim. The AnT was determined by linear interpolation between velocity and lactate concentration obtained in two sub-maximal repetitions of 400 m, assuming a fixed concentration of 3.5 mM lactate. Results The [La] in S30 was higher in GM than GF ( $3.97 \pm 1.46$  and  $2.68 \pm 0.82$  mM), but the %BF was lower in GM than GF ( $13.36 \pm 4.05$  and  $22.23 \pm 6.03$  %BF). There weren't difference between gender about AnT ( $1.19 \pm 0.09$  and  $1.19 \pm 0.06$  m.s<sup>-1</sup>) and S30 ( $1.14 \pm 0.09$  and  $1.13 \pm 0.09$  m.s<sup>-1</sup>) in males and females swimmers, respectively. Conclusion Therefore, some factors that might explain, at least in part, the different blood lactate response observed in female swimmers are muscularity and testosterone concentration, which might be higher in males (Keskinen & Komi, 1993). Moreover, the lower blood lactate response in swimmers could suggest that women may have different metabolic rates of carbohydrate and fat utilization during prolonged exercise. Thus, the blood lactate concentration during S30 seems to depend more of gender than aerobic performance level. References Keskinen KL, Komi PV (1993). J Appl Biomech, 9, 219-226. ## CHANGES OF THE STREAMLINE POSTURE BY A DIFFERENCE OF THE WATER DEPTH AMONG COLLEGE SWIMMERS

TANAKA, T., YOSHIMURA, Y., TAKAHASHI, Y., YASUKAWA, M., OISHI, K.

GRADUATE SCHOOL OF SCIENCE AND ENGINEERING, CHUO UNIVERSITY, TOKYO, JAPAN

**Introduction** Recently swimming techniques for competitive swimmers has been analyzed individually at four phases, i.e., the start phase, the stroke phase, the turn phase, and the finish phase. Those analyses provide the understanding of the importance for techniques at start and turn phases, e.g., the streamline and the dolphin kicking, in order to improve the swimming performance. However, those techniques have been usually assessed according to the subjectivity without evidence in many cases. In this study, we assessed the changes of the streamline and water resistance of swimmers according to the difference of the water depth during pulling by the mechanical steady force. **Methods** Subjects were eleven male competitive college swimmers who had reached the national and collegiate levels (two breaststroke, eight freestyle, and one individual medley swimmers). We used a pulling assist system, including the wire line to pull subjects who kept the streamline with the steady force of 65 N for 25 m. These trials were done at two water depths, i.e., from 25 cm to 45 cm (Shallow) and from 80 cm to 100 cm (Deep). At this time, subjects' moving velocity changes were measured precisely with a speed meter built-in the pulling system, and subjects' posture changes were analyzed with a video analysis system. **Results** The differences of mean velocities between at the two water depths were approximately zero for two subjects. However, for the other nine subjects the velocities were smaller at Shallow compared with at Deep. Additionally, the size of the velocity differences was related to the streamline change size because of the water depth change (Wilcoxon rank sum test,  $p < 0.01$ ). Namely, when the angles between the upper body and the legs were larger (the straight streamline changed to be V-shaped), the velocities were decreased ( $r = 0.53$ ). **Discussion** To keep the streamline was easier at Deep than at Shallow, because of the higher water pressure which assisted to keep the posture. It was suggested that the water resistance increased and therefore, the velocity decreased at shallow water for nine subjects. **Conclusion** Our results supported the importance for techniques to keep the streamline straight in start and turn phases, in order to improve the performance.

## INCREASING STROKE RATE IMPROVES ARM COORDINATION AND DECREASES INTRACYCLIC VELOCITY VARIATION IN FRONT CRAWL SWIMMING

YUJI, M.

KYOTO UNIVERSITY

**Increasing stroke rate improves arm coordination and decreases intracyclic velocity variation in front crawl swimming** Yuji Matsuda. 1, Yosuke Yamada. 2, Yasushi Ikuta. 1,3, Shingo Oda. 1 1: Graduated school of Human and Environmental Studies, Kyoto university, Kyoto, Japan. 2: Fukuoka University, 3: Osaka Kyoiku university. **Introduction** Swimming velocity is not stable and fluctuating even in a stroke cycle, and the decreased intracyclic velocity variation (IVV) will lead to swimming efficiency (Barbosa et al., 1996). However, it is not well known what swimming techniques decrease IVV. The purpose of this study were 1) to examine whether manipulating stroke rate (SR) affects the arm coordination (Idc) and IVV and 2) to examine whether using kick affects IVV. **Methods** Eight collegiate male swimmers performed the following two tests (average age:  $21.6 \pm 2.3$  years). Test 1: The swimmers swam at their maximal swimming velocity with imposed stroke rate (SR) (35, 40, 45, 50, 55, 60 cycle min<sup>-1</sup> and ad libitum). Test 2: The swimmers swam at maximal velocity with arm only (A), arm and kick (AK), and arm and fin kick (AF) at imposed SR (45 and 55 cycle min<sup>-1</sup>). Two cameras were used to film the swimmers from the right and left side views with panning. Idc was calculated as the lag time between the propulsive phases of each arm (Chollet et al., 2000). IVV was determined from the coefficient of variation of the head horizontal velocity within one stroke cycle. **Results** Idc significantly increased (Idc: from  $-9.27 \pm 3.68\%$  at SR35 to  $3.03 \pm 0.90\%$  at SR60) and IVV significantly decreased (from  $8.52 \pm 1.22$  at SR35 to  $4.72 \pm 1.63$  at SR60, by 45%) with increased SR. Moreover a highly significant correlation was found between Idc and IVV ( $r = 0.965$ ,  $p < 0.01$ ), suggesting that IVV decreased with increasing Idc. In contrast, there was no difference in Idc and IVV among A, AK, and AF. **Discussion** With increasing SR, Idc was increased and IVV was decreased. The high correlation between Idc and IVV suggest that decreased IVV was induced by increasing Idc. When Idc was higher, there was less non-propulsive phase in a stroke cycle, and the velocity would be maintained in a stroke cycle, which leads to lower IVV. In contrast, there was no difference in IVV among three kick conditions (A, AK and AF). It is confirmed that using kick and fin improved average swimming velocity, but do not affect IVV. The results suggest that the changing arm coordination, but not kicking, affects IVV in front crawl swimming. **Reference** Chollet D, Challes S, Chatard JC. (2000). ## EVALUATION OF STARTING REACTION TIME OF TURKISH SWIMMERS

GUMUS, M.1, AKALIN, T.C.1

ZONGULDAK KARAELMAS UNIVERSITY

**Gumus, M.1, Akalin, T.C.1 1: ZKÜ (Zonguldak, Turkey)** **Introduction** It is well known that race time of winner or loser in swimming competitions sometimes change in a few milliseconds. Starting reaction can play a major role in race time as it is an influential component of swimming. The aim of study was to evaluate of starting reaction time of Turkish swimmers participated to Turkish National Championships. **Methods** In this study, 2328 official competition times of 532 swimmers (218 female, 314 male) who participated in Turkish National Championships 2010 performed in Istanbul, Turkey by permission of Turkish Swimming Federation. Championship was performed in 50 m indoor swimming pool of Istanbul Technical University and the data of starting time -elapsed from the electronic start signal to the moment of last contact- measurements were obtained by SWISS TIMING (OMEGA) that is official partner of FINA. Data were evaluated by using SPSS for Windows 16.0 software and mean values were represented as "arithmetic mean  $\pm$  standard deviation". ANOVA test, student t test, posthoc Bonferroni test and pearson correlation analysis were used for the comparisons between the measurements. **Results** of analysis were evaluated with 95% confidence interval. **Results** Mean starting reaction time (SRT) of all swimmers was  $0.78 \pm 0.07$  seconds. SRT was  $0.81 \pm 0.09$  seconds for female,  $0.79 \pm 0.09$  seconds for male and there was a significant difference between groups ( $p = 0.001$ ). There was a positive and significant correlation between SRT and race distance ( $r = 0.249$ ,  $p = 0.001$ ). In free style swimmers, SRT was significantly lower than the others ( $p = 0.001$ ). SRT was  $0.81 \pm 0.12$  seconds for 13 years old,  $0.81 \pm 0.09$  seconds for 14 years old,  $0.80 \pm 0.09$  seconds for 15 and 16 years old,  $0.79 \pm 0.09$  seconds for 17 and 18 years old,  $0.78 \pm 0.08$  seconds for 19 and over years old swimmers, and there was a negative and significant correlation between SRT and age groups ( $r = 0.101$ ,  $p = 0.001$ ). In championship, there was a significant difference between competition categories by SRT ( $p = 0.001$ ) and SRT was  $0.81 \pm 0.09$  seconds for elimination races,  $0.78 \pm 0.09$  seconds for semi-finals and  $0.79 \pm 0.09$  seconds for finals. **Discussion** In this study mean SRT was  $0.78 \pm 0.07$  seconds. SRT

was reported between 0.6-0.8 seconds in several studies. Accordingly, SRT of Turkish swimmers may be determined as relatively longer than the others. STR is related with performance and success. This study is the first research about SRT of Turkish swimmers and will provide the basis for improving the training techniques and programmes for Turkish swimmers and their trainers. Furthermore, Turkish swimmers and trainers can evaluate their performance for international competitions and monitor their performance improvement by using these measurements regularly. ### **SOME REMARKS ON THE ACTIVE DRAG IN SWIMMING: AN APPROACH USING SIMPLIFIED MODEL**

MATSUUCHI, K.

UNIVERSITY OF TSUKUBA

SOME REMARKS ON THE ACTIVE DRAG IN SWIMMING: AN APPROACH USING SIMPLIFIED MODEL Matsuuchi, K.1 1: University of Tsukuba (Tsukuba, Japan) Introduction In human swimming, the drag is equivalent to the propulsion in the averaged meaning. In this context the drag means not static but active drag. Several approaches to measuring the active drag have been proposed (Hollander et al., 1986; Kolmogorov et al., 1992; Xin-Feng et al., 2007). However, it is not clear how to define the active drag or to measure it correctly. Therefore it is impossible to compare the results obtained by the various methods. Our aim is to obtain an understanding on the basic characteristics of the drag. The force exerted on hand affects the motion of trunk, or the center of gravity. The response of the trunk is investigated using a simplified mathematical model. The solutions are obtained both numerically and analytically. Swimming speed and the work done by the force are considered. Methods For establishing the equation of motion it was supposed that the direction of motion is unidirectional, and no rotation of the trunk is taken into account. Moreover the drag is supposed to be proportional to the square of swimming velocity. The equation including the propulsive and drag forces on the right-hand side is derived. The two forces on the right-hand side are both functions of time. The equations are solved numerically and analytically. In the analytical method the variables are expanded into Fourier components. To verify the numerical results the analytical solutions are compared and investigated the time dependence of the drag variations. Results Multiplying the velocity and integrating once the equation with respect to time over a period, we can show that the work done by propulsive force is equal to that by the drag. In other words, the work done by the propulsive force is equivalent with that by the drag. Numerical results show that the active force is strongly dependent on the amplitude of velocity fluctuation. It was found that the numerical results agree fairly well with the analytical result. It is then concluded that in understanding the drag correctly the contribution of fluctuations has to be taken into account. Discussion Estimating the magnitude of active drag in a correct manner has been a main concern in biomechanics in swimming. Confining ourselves to the translational motion, the response to the functional form of propulsive force was considered using a simplified model equation. It was found that the center of gravity can be sensitively responded by the variation of force fluctuation, or velocity variation. #### **THE EFFECTS OF STATIC AND DYNAMIC STRETCHING ON COMPETITIVE GYMNASTS' SPLIT JUMP PERFORMANCE**

HARPER, E., WALSH, M., BALDWIN, C.

MIAMI UNIVERSITY

THE EFFECTS OF STATIC AND DYNAMIC STRETCHING ON COMPETITIVE GYMNASTS' SPLIT JUMP PERFORMANCE Harper, E.N., Walsh, M.S., Baldwin, C.C. Miami University (Oxford, Ohio, USA) Introduction In the past researchers, such as Power et al. (2004), have reported that static stretching preexercise has a negative effect on performance variables. Other researchers have since investigated the differing effects on performance between static and dynamic stretching preexercise. Commonly, dynamic stretching proves to have different effects on performance variables than static stretching (for example see Hough et al., 2009). Currently, little research has looked beyond general performance measures, such as running, jumping, and force production. More research studies are needed, particularly those that are sport-specific. The purpose of this study was to evaluate the effects of no stretching (NS), static stretching (SS), and dynamic stretching (DS) on competitive gymnasts' split jump performance. Methods Twelve female competitive gymnasts completed three split jump trials on a force plate with simultaneous motion capture following each stretching protocol. The stretching protocols were preceded by a 5 minute walking warm-up on a treadmill. Each of the stretches were performed on both the right and left leg. The SS protocol consisted of performing a split for 1 min and three modified split stretches for 45 seconds each. The DS protocol consisted of standing forward, backward, and forward-backward combined leg swings (3 sets of 10 each) and a dynamic stretch for the plantar flexors. Results Repeated-Measures ANOVAs were used to access differences between stretching protocols for each of the dependent variables (flight time, max split angle, and change in center of mass height). No statistical significance between the three stretching protocols was found. Discussion This study is one of few to measure the effects of stretching preexercise on sport specific performance variables. These findings conflict with previous research comparing acute dynamic and static stretching, suggesting that both static and dynamic stretching produced negligible differences in split jump performance. It is important to note that the stretches performed by the gymnasts and the amount of stretching was selected specifically to mimic what is commonly done in gymnastics training and to be sensitive to the allocated time athletes typically have to devote to preexercise routines. This is of interest to those presented with the question of what to incorporate into a preexercise warm-up routine to optimize performance. References Hough P, Ross E, Howatson G. (2009). ## ENERGY EXPENDITURE DURING ARTISTIC GYMNASTIC TRAINING SESSION OF ELITE YOUNG MALE ATHLETES.

MASSIDDA, M.1,2, MOSSA, D.2, CALO, C.M.1

UNIVERSITY OF CAGLIARI

**Introduction** The qualities necessary to achieve high levels of performance in artistic gymnastics are today well defined: power, strength, speed, flexibility and coordination (Jemni et al. 2001). Although a lot of studies evaluated the gymnasts' anaerobic power by means of laboratory tests, such as Wingate, only few studies have been focused on the blood lactate formation or heart rates monitoring during sport-specific situations (Jemni et al. 2003). To our knowledge, there are no studies that had quantified the Energy demands during a typical training session of artistic gymnastic in young elite athletes. The aim of the present study was to quantified the intensity of physical activity (PA) and the Energy Expenditure (EE) of young elite gymnasts during a typical pre-competition training session (TS) and for each gymnastic routines [Vault (V), Pommel Horse (PH), Rings (R), Parallel Bar (PB), Horizontal Bar (HB) and Floor Exercise (FE)]. **Methods** Ten elite Italian young male gymnasts (age  $11.8 \pm 1.6$  yr; stature  $144.1 \pm 1.6$  cm; weight  $38.9 \pm 10.7$  kg) competing in Artistic Gymnastic at the National level were examined in this study. The EE (kcal) was measured continuously during the different phases of the TS and during each gymnastic routines using the SenseWear Pro Armband (SWA). Paired-sample t-tests were used to determine differences in the metabolic equivalent (MET) and EE (Kcal) values between each routines. Results The total time of TS was  $3.2 \pm 1.6$  hours (16% warm up and flexibility, 17% power and strength training; 16% HB; 15.5% FE; 11% PB; 10% PH; 9.5% R and 5% V) and the EE for the entire TS was  $882.2 \pm 155.8$  kcal. The intensity of PA during the different phases of TS ranged from moderate (3–6 METs) to very vigorous (>9 METs). The PA intensity was vigorous for 52.2% of the total time of TS. Among all the gymnastic routines the PH (59.7 s; 8.5 METs; 30.8 kcal) and the FE (78.1 s; 8.4 METs; 32.7 kcal) showed the highest MET and EE values. **Discussion** Physiological studies during artistic gymnastic performance are regrettably few due to its peculiarities in duration and nature of activities. Our results demonstrate that typical pre-competition TS of young elite male gymnasts is a very heavy exercise that required a high intensity level of PA for the most of TS time. This finding could also reflect the high heart rate values reported in previous studies on gymnastic routines (Goswami and Gupta, 1998). The possibility of monitoring variables during normal training by mean of SWA can improve training protocols and control the gymnasts' fitness levels. **References** Goswami A, Gupta S. (1998). ## SPEED AND POWER IN FENCERS OF DIFFERENT LEVELS

WEICHENBERGER, M.1, LIU, Y.1, STEEGMÜLLER, W.2, ZIMMERMANN, T.3, STRIGEL, D.2, STEINACKER, J.M.1

1: DEPARTMENT OF SPORTS MEDICINE AND REHABILITATION, UNIVERSITY OF ULM, ULM, GERMANY 2: GERMAN FENCING FEDERATION (IDBF), BONN, GERMANY 3: NATIONAL FENCING BASE, HEIDENHEIM, GERMANY

**Introduction** A fast and explosive footwork is regarded as an important precondition for the competition success in fencing, however data have rarely been published. The speed and power especially of the lower limbs should be excellent and better in fencers of higher levels. The aim of the study was the determination of speed and power in fencers of international and national level. **Methods** 8 male German top-level epee fencers (TLE), 17 junior epee fencers of international (JIN) and 30 junior epee fencers of national level (JNA) took part in the study. The measurements were focused on speed at footwork forward (FW\_F), footwork backward (FW\_B), footwork forward and backward with change of direction (FW\_F+B) and 3m-Sprint (3mS). To determine power Counter-Movement Jumps (CMJ) and Squat Jumps (SJ) were performed on a force plate (Quattro Jump, Kistler). Reactive strength index (RI) was determined by Drop Jump (Opto Jump, Microgate). Performance of groups was compared by oneway analysis of variance (ANOVA). Results Fencing-specific movement speed of TLE was higher (FW\_F:  $1.01 \pm 0.07$ s, FW\_BW:  $1.06 \pm 0.02$ , FW\_F+B:  $2.18 \pm 0.08$ s) than in JIN ( $1.08 \pm 0.08$ s,  $1.16 \pm 0.08$ ,  $2.28 \pm 0.13$ s, n.s.) and JNA ( $1.13 \pm 0.09$ s,  $1.23 \pm 0.11$ s,  $2.41 \pm 0.14$ s,  $p < .05$ ), whereas differences in 3mS were not significant. Jumping performance of TLE (SJ:  $49.2 \pm 2.9$  cm, CMJ:  $52.4 \pm 3.5$  cm, DJ (RI):  $3.0 \pm 0.4$ ) was better than for JIN ( $47.2 \pm 5.2$  cm,  $49.7 \pm 5.5$  cm,  $2.8 \pm 0.4$ , n.s.) and for JNA ( $43.3 \pm 5.2$  cm,  $45.8 \pm 5.1$  cm,  $2.7 \pm 0.4$ ,  $p < .05$ ). SJ and CMJ correlate with FW\_F+B ( $r = -.63$ ,  $p < .01$ ,  $r = -.65$ ,  $p < .01$ ). **Discussion** Results emphasize the importance of a fast and explosive footwork for success in fencing. For determining speed in fencers, specific tests that take special requirements (e.g. footwork, change of direction, weapon) into account are more suitable than sprints. Jumping performance correlates with movement speed in fencing which points to significance of power in lower limbs for acceleration, fast change of direction and performing lunge. **References** Felder H (2003). ## 2009 PORTIMÃO RHYTHMIC GYMNASTICS WORLD CUP.SCORES ANALYSIS.

ÁVILA-CARVALHO, L., LEANDRO, C., LEBRE, E.

PORTO UNIVERSITY

The performance in rhythmic gymnastics (RG) is evaluated in competition by a final score that includes 3 sub-scores: Difficulty, Artistic and Execution scores. The level of RG performance has been continuously improved in the last years. Those improvements were always ruled by the modifications in FIG (International federation of gymnastics) code of points (Ávila-Carvalho et al., 2008b). The difficulty score represents the body and apparatus difficulty level that the gymnast or the group can achieve (Ávila-Carvalho et al., 2008a). The artistic score main goal is the evaluation of the emotional message projection to the public (and judges) and to display the choreographic idea with an expressive interpretation guided by the following three aspects: music accompaniment, artistic image and expressivity (FIG, 2009). According Lebre, (2007) the main liability of the final score depends on the artistic score. The execution score represent the quality of the performance that the gymnasts can do. In order to understand some of the consequences of the use of the present code of points in RG we analyzed the Difficulty score (D1 and D2) and of the Artistic and Execution score some in the 2009 Portimão RG World Cup Series. All forms and scores from the 47 gymnasts present in 2009 Portimão RG World Cup general competition were analyzed. The departure scores (Ds) for D1 and D2 were registered, as well as the final score (Fs) achieved by the gymnast. The analysis was made for the entire sample in one group, and for the entire sample divided in 3 groups: 1st, 2nd and 3rd part of the final ranking for each apparatus. The descriptive statistics were performed using the average as a measure of central tendency and standard deviation as measures of dispersion. We present also the minimum and the maximum value of data. We also apply a correlation test between D2 and D1 scores and artistic and execution scores. Results: In D1 and D2 scores: a) There was a big difference between the scores proposed by the coaches in the competition forms and the difficulties that judges could identify; b) As lower is the position of the gymnast in the ranking, higher was the difference between the departure and final score, nevertheless those differences are shorter in D2 scores. In execution and artistic

scores: a) The execution and the artistic scores were almost the same for each group of gymnasts (1st, 2nd and 3rd part of the final ranking) for all groups and for all apparatus; b) These results might show one of two situations: or the judges were not evaluating what they suppose to do or the code of points made the judges evaluate twice the same aspects.

### UCHI KOMI VS NAGE KOMI IN A JUDO SPECIFIC TEST AMONG MALE ATHLETES

BLASCO-LAFARGA, C.I, PABLOS, C.I, CARRATALÁ, V.I

UNIVERSITY OF VALENCIA, SPAIN

**Introduction** There is some lack of scientific information about the utility of technical skills repeated stereotypically in judo training (eg. Uchi Komi & Nage Komi). Notwithstanding, these skills are included in any proposal of Judo valuation. Almansba et al (2007) focused the assessment on UK; while Franchini et al. (2010) have worked on the NK "Judo Special Fitness Test" since 1995. However, to our knowledge, no one has analyzed the relationship between them. In 2009 we developed the Blasco Judo Test, combining UK and NK with some specific RFD-Strength skills (eg. pull-ups, gripping up and down a rope and a final TUM isometric pull-up). The test has already shown to be valid, reliable (Blasco et al. 2010) and able to discriminate regarding the Performance. Our purpose now is to analyze the relationship among UK, NK and other conditional demands, under fatigue, within a time-line structure similar to the contest. **Methods** 24 male Spanish Judo competitors (national e international level,  $10.15 \pm 3.4$  years in competition) age  $21.14 \pm 3.26$ ;  $74.53 \pm 9.79$  kg,  $11.36 \pm 2.10\%$  fat;  $175.78 \pm 6.66$  cm) were tested close to their main competitions. Partial correlations, controlling for age and weight, were used to analyze the relationship between the maximum number of UK achieved in the three series comprising the test vs. the maximum number of NK, Pull-ups, repetitions in the rope, and TUM Isometric Strength. (UK and NK were played twice: techniques for a symmetric and asymmetric opponent). **Results** T Blasco total score (ti):  $211.29 \pm 28.62$  rep; TUM isometric pull-up:  $22.66 \pm 8.61$  s; NKt:  $42.29 \pm 5.61$ ; UKt:  $50.58 \pm 8.26$ ; Rope Gripping-t:  $78.67 \pm 14.24$ ; Pull-ups-t:  $25.54 \pm 8.35$ . While Partial correlation showed significant moderate to big correlations among NK (symmetric, asymmetric, and the addition of both) and all the strength exercises in the test, UK (symmetric, asymmetric and their addition) showed no correlation with NK, pull-ups or the rope exercise. **Discussion** In previous studies, Blasco total score, jointly with total pull-ups, rope ( $p < 0.001$ ), and NK ( $p < 0.005$ ), showed significant differences with regard to Performance. Meanwhile, UK did not show any statistical significance. Partial correlations match the idea of a closer relation among NK and the strength requirements in competition, while UK shows again a different trend. We need further studies to deepen in the meaningful and application of these differences. **References** Almansba R, Franchini E & Sterkowicz S. (2007). *Science & Sports*, 22, 216–223. ### CHANGES OF POWER-VELOCITY RELATIONSHIP IN JUDO ATHLETES

BUŠKO, K., BOGUSZEWSKA, K., LIPÍŃSKA, M.

JOSEF PILSUDSKI UNIVERSITY OF PHYSICAL EDUCATION

**Introduction** Success in judo requires perfect physical and tactical preparation (Franchini et al., 2005). Professional literature includes a number of works on exercise physiology of male and female judoists (Callister et al., 1991), but there are very few studies concerned with judoists' biomechanics (Buško and Nowak, 2008). The aim of the study was to examine changes of power-velocity relationship of lower extremities during training. **Methods** The study was conducted on eight judo athletes (age  $15.5 \pm 0.8$  years, body height  $173.3 \pm 9.7$  cm, body mass  $69.2 \pm 14.0$  kg and training experience  $7.5 \pm 1.9$  years). Force-velocity (F-v) and power-velocity (P-v) relationship were determined from five maximal cycle ergometer exercise tests, 10 s each, with increasing external loads amounting to 2.5, 5.0, 7.5, 10.0, 12.5% of body weight (BW). There were 2-min breaks between the tests. Three measurements were carried out: before the second preparatory period (I), after the second preparatory period (II) and after the second starting period (III). The results were statistically processed using analysis of variance (ANOVA) with repeated measures (post-hoc Tukey test). **Results** The absolute power output at the load of 2.5, 7.5, 10.0 and 12.5% BW were statistically significant increase after the second preparatory period (II,  $p < 0.05$ ) and after the second starting period (III,  $p < 0.05$ ). The relative power output at the load of 2.5% and 5.0% BW insignificant increased between the measurements I and III by 3.7% and 2.0%, respectively. The relative power output at the load of 7.5% BW increased from  $10.11 \pm 1.10$  W/kg (I) to  $10.58 \pm 0.94$  W/kg (II) and  $10.41 \pm 0.94$  W/kg (III). The relative power output at the load of 10.0% BW was observed from  $10.49 \pm 1.37$  W/kg (I) to  $11.14 \pm 1.04$  W/kg (II) and  $11.06 \pm 1.26$  W/kg (III). The relative power output at the load of 12.5% BW increased from  $9.01 \pm 1.98$  W/kg (I) to  $10.55 \pm 1.60$  W/kg (II,  $p < 0.05$ ) and  $10.43 \pm 0.87$  W/kg (III,  $p < 0.05$ ). **Discussion** The measurement of the maximal static muscle torque and maximal power output of legs yields valuable information that can be extremely useful in judo training planning (Häkkinen, 1989). In our study absolute power output has increased significantly during the analyzed period. When the values of power output are divided per kilogram of body weight significant differences were observed only for the load of 12.5% BW. **Acknowledgements** The study was supported by Ministry of Science and Higher Education (Grant No. AWF - Ds.-134). **References** Buško K, Nowak A. ### EVALUATION OF TRAINING AND PERFORMANCE IN THAI BOXE

INVERNIZZI, P., SCURATI, R., LONGO, S., MICHIELON, G.

UNIVERSITÀ DEGLI STUDI DI MILANO

**Introduction** It is assessed that in the combat sports the best performance highly depends on technical-tactical and energetic features. Therefore particular attention have to be paid in fully understanding this assumption, questioning about the simplest but equally relevant ways to evaluate the peculiarities of the combat actions and to improve the planning of the training and its outcomes. Lehmann's test (1994), analysis of [La] and perceived exertion can be useful methods to exploit. The aim of this study was to examine these pointers and their relations with the performances in Thai-boxers at different level. **Methods** 10 non-competitive (NC) and 10 competitive (C) Thai-boxers volunteered in the study. The Lehmann's test (LT, 4 series of consecutive Jab punches for 6 s, 1 min rest) was twice repeated in two consecutive days. The number of Jab punches (JP), the [La] (by a fingertip blood sample, 3 min post-test) and the perceived exertion (RPE, by the Borg scale, 0–10) were collected. The outcomes of the matches performed by C athletes were also surveyed (victories,  $8 \pm 2.3$ , mean  $\pm$  SD). The reliability of LT, the differences between athletes by level and correlations of results after LT and the performances of the C athletes were accomplished. **Results** In NC, the ICC of JP, [La] and RPE were 0.89, 0.96 and 0.49, respectively. In C, the ICC of JP, [La] and

RPE were 0.87, 0.82 and 0.94, respectively. LT is then reliable both in NC and in C. C performed a significantly higher number of JP than NC ( $43.26 \pm 2.01$  vs  $48.05 \pm 2.95$ ,  $p < 0.01$ ), as well as they showed a lower [La] ( $6.93 \pm 0.92$  vs  $5.63 \pm 0.46$ , mM,  $p < 0.01$ ). No differences were found in RPE. In C, a significant negative correlation was found between [La] and JP ( $\rho = -0.98$ ,  $p < 0.01$ ). Positive correlation was found between the outcomes (victories) in the competitions and JP ( $\rho = 0.86$ ,  $p < 0.01$ ). Discussion In Thai boxers, the Lehmann's test is a proper and useful method to evaluate the ATP-PC System. The results showed that LT is directly related to the training level, then it can be easily employed by coaches as a training support. Furthermore, competitive athletes perform the test better than the non-competitive also thanks to the enhanced economy that their actions allow as a consequence of a more fully-developed technical skills. This economy also combines with the energetic outcomes of the training. The positive correlation between JP and the results (victories) in the competitions confirms that the high intensity of the punches combinations is an essential element in Thai boxe. ## WATER TRAINING IN COMBAT SPORTS

DISTASO, M., INVELITO, G., VILLANI, R.

*UIPASC*

**WATER TRAINING IN COMBAT SPORTS** Distaso, M., 1; Invelito, G., 1; Villani, R., 1 1:Italian Union Trainers of Combat Sports (UIPASC) Introduction The aim of this research was to test a new training method of the rapidity action of the roundhouse kick in combat sports, using the natural resistance of water. Materials and Methods To determine whether the performance of technical movements in the water, could be beneficial also on the rapidity of the technique on the mat, we organized a standardized protocol administered to 20 male athletes practicing kick boxing (years 18/30; height 1,67/1,85 cm; weight 67/90 kg), divided into two homogeneous groups: 10 athletes formed the experimental group, and 10 the control group. Then, to know the initial speed of each athlete, we administered to both groups, the SOK test (Speed of Kick), a system composed of photocells and ergotester that allows us to know the real speed of execution of the roundhouse kick. The experimental group played 12 training sessions in the pool, for a period of one month, in which they performed the technique as quickly as 6 times for 8 series, with both legs. The recovery time between repeats was 2 seconds and 3 minutes between sets. Instead, the control group, continued for the duration of the 12 sessions, only and exclusively the traditional punching bag training. At the end of training in the pool, was administered to two groups, the SOK initial test, to show the actual speed increase. Results After the training period in water, the experimental group showed, in executing the roundhouse kick, times lower than in the control group. The speed improvement obtained in the post-training is to be considered significant. Experimental group (mean: 0.18 sec pre-training, post-training 0.14 sec, difference 31.30%), control group (mean: 0.19 sec pre-training, post-training 0.18 sec; 14.30% difference). Discussion Given the scope for improvement in the experimental group of the speed action of the roundhouse kick, we can say that this training method, based on the water resistance, has given excellent results in terms of increased of speed action, an essential component for the explosive kick in kick boxing. ## DIFFERENCES IN THE USE OF TECHNICAL AND TACTICAL ELEMENTS BY WINNERS AND DEFEATED K-1 SUPER HEAVY-WEIGHT FIGHTERS, JAPAN 2010

KAPO, S., RADJO, I., CIKATIC, B., KAJMOVIC, H., KAFEDJIC, E., HASANOVIC, E.

*FACULTY OF SPORTS AND PHYSICAL EDUCATION, UNIVERSITY OF SARAJEVO*

**Introduction** What this article aims to do is to identify K-1 fighters' situational efficiency parameters by registering the use of a group of tactical and technical elements applied by the winners and defeated fighters in the Final K-1 Grand Prix Tournament in Japan in 2010. **Methods** The sample consisted of eight top-level K-1 super heavyweight fighter specialised in different contact sports (boxing, kick boxing, karate, muay thai, etc.) fighting according to K-1 rules. Data were collected on the basis of video recordings of seven fights, based on which the K-1 tournament analysis was performed. The collected data were processed using descriptive statistics. Variables were processed using the formula for the technical and tactical elements application efficiency in K-1 fights  $K - 1 = x / Ny \times 100$  %. **Results and discussion** Basic descriptive parameters of technical and tactical elements indicate that the total frequency of punches in the winners at this tournament is 732 or 56.5 %, whereas that frequency in the defeated K-1 fighters is 562 or 43.5 % of the total number of hand techniques used. The winners were dominant in the use of all hand techniques with regard to the defeated fighters. The most frequent punches were the direct punches 414 or 32 % and hooks to the head 257 or 19.8 %. The winners also more frequently used kicks than the defeated fighters. They used them 358 times or 57.4 %, whereas the defeated fighters used them 267 times or 42.6%. The winners most frequently used low circular kicks 204 or 32.5 %, and their application of a large number of technical and tactical elements was more diverse than that of the defeated fighters. The use of basic and advanced defence techniques is more frequent with the defeated fighters 764 or 53.5 %. The same frequency for the winners was 663 or 46.5 %. The winners used offensive tactics and attacking techniques 5 or 71%, which resulted in their victory, whereas the defeated fighters used a defensive and combined tactics. That suggests that they used defensive techniques more than the offensive ones. The manner in which the victory was achieved 4 or 57.1 % by decision, 2 or 28.6% by knock-out, 1 or 14.2 % by forfeit due to injury. That suggests that the offensive and attacking techniques are essential for fighting efficiently in K-1. **Conclusion** The gathered statistical indicators suggest that success in K-1 is determined by the level and structure of a large number of abilities, skills, and characteristics that can be measured and analysed, as well as improved with appropriate means and methods through a fighter's career. ## EFFECTS OF FATIGUE ON TRUNK STABILITY IN ELITE-GYMNASTS

VAN DER EB, J., LUGER, T., VAN DIEËN, J.H.

*VU UNIVERSITY AMSTERDAM*

**Introduction** Training of (factors underlying) trunk stability has been suggested as a means to improve performance and reduce injury risk in athletes. However, up to date there is limited evidence on factors that determine trunk stability in athletes. The aim of the present study was to test the hypothesis that fatigue induced by a series of exercises that represent a normal training effort would lead to a decrement of trunk stability in elite, female gymnasts. Nine girls, all national top-level gymnasts, participated in the study. Participants mean  $\pm$  standard deviation age, height and mass were  $12.4 \pm 2.3$  yrs,  $1.47 \pm 0.12$  m and  $39.0 \pm 12.92$  kg, respectively. Participants and their parents

provided informed consent before participation. **Methods** As a measure of core stability the participants were subjected to a series of balancing tasks before and after a fatigue protocol. The fatigue protocol consisted of four series of five dump handstand exercises on the bar were performed. This set of exercises is comparable to efforts in normal training and competitive events. One balancing task (three trials) was sitting as motionless as possible on a seat, with a feet rest and hands on lap, fixed over a hemisphere to create an unstable surface (Dieën et al., 2010b). The hemisphere was placed on a force plate to track the location of the contact point (CP) of the hemisphere on the force plate. In addition, nine sudden release trials were performed in which the seat was backward inclined over a set angle and suddenly released after which the subject had to regain balance. The sway amplitude and sway frequency in unperturbed sitting were determined from the CP time series and were averaged over the three trials. In addition, the maximum displacement and the exponential rate of recovery of the CP location after the sudden release were determined and averaged over nine trials. **Results** After the fatigue protocol, sway amplitude in the fore-aft direction was significantly increased ( $p=0.03$ ), while sway frequency was decreased ( $p=0.005$ ). In addition, the maximum displacement after the sudden release was increased ( $p=0.009$ ), while the rate of recovery after the perturbation was decreased ( $p=0.05$ ). **Conclusions** Fatigue induced by series of exercises representing a realistic training load caused a measurable decrement in dynamic stability of the trunk in elite-gymnasts. The results of this study suggest that endurance training of trunk muscles is indicated to maintain trunk stability during training sessions and competitive events even in well-trained athletes. ## PHYSIOLOGICAL AND HORMONAL RESPONSES TO PERFORMING SIMULATED AND CHAMPIONSHIP TAEKWONDO COMBATS

BRIDGE, C.A.1, DRUST, B.2

1 EDGE HILL UNIVERSITY, UK; 2 LIVERPOOL JOHN MOORES UNIVERSITY, UK

**Introduction** Simulated Taekwondo combats have tended to elicit reduced physiological load than equivalent championship Taekwondo combats (Bridge et al. 2009; Butios and Tasika, 2007). The mechanisms that govern this response have not been elucidated. There is evidence to suggest that this phenomenon may be a function of dissonant stress hormone responses in these combat settings (Obminski, 2008). The aim of this study was to compare the physiological and stress hormonal responses to performing Taekwondo combats in simulated and championship settings. **Methods** Ten male Taekwondo black belts (mean  $\pm$  SD, age  $18 \pm 1$  years, body mass  $64.5 \pm 11$  kg, height  $1.77 \pm 0.08$  m) were examined during the first combat in an international championship event and during a simulated combat. The championship combats comprised three two-minute rounds of full-contact combat with one minute separating each round. In the simulated combats, participants performed an exercise protocol that replicated the structure and activity profile (physical workload) performed in the championship Taekwondo combats. The championship and simulated combat trials were separated by a period of two weeks. Participants were instructed to replicate the same warm up and nutritional practices for each combat. Heart rate (HR) was recorded at 5 s intervals during the combats. Venous blood samples were obtained before and after each combat to determine the plasma metabolite and hormone concentrations. **Results** Significantly higher ( $P < .05$ ) HR ( $136 \pm 13$  vs.  $116 \pm 10$  beats.min<sup>-1</sup>), plasma lactate ( $2.6 \pm 0.9$  vs.  $1.2 \pm 0.7$  mmol.l<sup>-1</sup>), and glucose ( $6.7 \pm 0.9$  vs.  $5.6 \pm 1.2$  mmol.l<sup>-1</sup>) concentrations were evident before the championship combats than before the simulated combats respectively. The championship combats also induced higher ( $P < .05$ ) HR during combat than the simulated combats ( $188 \pm 8$  vs.  $172 \pm 4$  beats.min<sup>-1</sup>). Significantly higher ( $P < .05$ ) plasma lactate ( $12.2 \pm 4.6$  vs.  $3.6 \pm 2.7$  mmol.l<sup>-1</sup>), glucose ( $10.3 \pm 1.1$  vs.  $5.9 \pm 0.8$  mmol.l<sup>-1</sup>), glycerol ( $143 \pm 49$  vs.  $78 \pm 21$   $\mu$ mol.l<sup>-1</sup>), epinephrine ( $2.7 \pm 1.7$  vs.  $0.6 \pm 0.2$  nmol.l<sup>-1</sup>) and norepinephrine ( $14.3 \pm 9.4$  vs.  $3.0 \pm 1.1$  nmol.l<sup>-1</sup>) concentrations were evident after the championship combats than after the simulated combats respectively. **Conclusions** The findings of this study demonstrate that championship Taekwondo combats augment the physiological and hormonal responses in comparison to simulated combats. These contrasting physiological and hormonal profiles seem to be mediated primarily by the different stress responses to these combat settings. **References** Bridge C.A. et al. ### PP-PM74 Physiology: High Intensity Training

#### EFFECTS OF MAXIMAL AND SUBMAXIMAL TRAINING ON COAGULATION TIME OF NONATHLETE FEMALE STUDENTS

RADMEHR, E.

ISLAMIC AZAD UNIVERSITY, BUSHEHR BRANCH

The aim of the current investigation was to determine of the effects of maximal and submaximal training on coagulation factors (platelet, hematocrite, coagulation time, tromboplastin partial time, and trombine time) of nonathlete female students of college. The reason of this study was lack of adequate information about coagulation in compare of training rates. For this purpose, 10 volunteer students have performed two maximal training (Bruce protocol, running on treadmill until exhaustion) and submaximal training (Bruce protocol, running on treadmill until reaching to 75% of predicted maximal heart rate), separated by 10 days. Blood samples of four situations including fasting, before, immediately and 30 minute after both training has acquired and analyzed. Data has analyzed by analysis of variance (ANOVA) and post hoc test of tukey in significant level of .05. The least significant value is computed and reported by SPSS statistical package. Results have shown that both maximal and submaximal training has no effects on protrombine time and coagulation time. Hematocrite increased significantly after both training. Partial tromboplastin time increased after maximal training and platelet increased significantly after submaximal training. The difference between research results is probably attributed to different training protocol, method and time of coagulation factors measurement, and subjects. It is concluded that special load may be effective in process of coagulation, but also we need to more studies for clear results.

## EFFECTS OF 3 WEEKS OF HIGH INTENSITY INTERVAL TRAINING WITH LOW VOLUME ON SPRINT PERFORMANCE AND PLASMA URIC ACID

STAVRINO, P., BOGDANIS, G.C., MARIDAKI, M.

UNIVERSITY OF ATHENS, FACULTY OF PHYSICAL EDUCATION AND SPORTS SCIENCE

**INTRODUCTION** It has been shown that low volume sprint training on a cycle ergometer increases peak but not mean power output during four all-out 30 s sprints (Burgomaster et al. 2005) after only six sessions. This study investigated whether performing this type of training with a predetermined constant "optimal" pace may improve the effectiveness of this training method. It was also hypothesized that this type of training would reduce purine loss from the muscle, as indirectly indicated by plasma uric acid. **METHODS** Eight university students trained 3 times per week with 1-2 days rest between training sessions for 3 weeks. In every training session the subjects performed four to six 30s bouts on a cycle ergometer at a constant pace of 100 rpm against a resistance equivalent to the mean power output of a baseline Wingate test with 4 min rest between bouts. In the last training session subjects completed four constant pace 30 s sprints against a new resistance equivalent to the mean power output generated in a Wingate test performed 24 hours before that session. Venous blood samples were taken at rest, 0.5h, 24h and 48h after first and last training sessions for uric acid analysis and capillary arterialized samples were taken at rest and 2 min after 2nd and 4th sprint, at the first and last training sessions for lactate determination. Two-way analyses of variance for repeated measures ( $p < 0.05$ ) and a Tukey post-hoc test were used for data analysis. **RESULTS** Mean power output (MPO) during the Wingate test increased significantly by 6.4%,  $p < 0.05$  ( $663.4 \pm 15.3$  vs.  $705.7 \pm 20.3$  W). Also, MPO during each of the repeated four 30 s bouts increased by 6-12%. Blood lactate 2min after the last sprint was significantly higher post-training ( $20.7 \pm 1.2$  vs  $18.3 \pm 1.0$  mmol/L,  $p < 0.05$ ). Repeated sprints caused elevation of uric acid 0.5 and 24 hours after the four sprints and returned to baseline 48 hours after exercise. Training caused a 13-15% decrease in plasma uric acid 0.5 and 24 hours after the repeated sprints ( $p < 0.01$ ). **DISCUSSION** The present study demonstrated that nine sessions of high intensity training at constant pace induced a relatively large increase in mean power output during single and repeated bouts. Furthermore the reduction of uric acid likely represents a training-induced adaptation to minimize the loss of purines from skeletal muscle (Stathis et al., 2006). **REFERENCES** Burgomaster, K. ## ACUTE PHYSIOLOGICAL RESPONSE TO INTENSIVE AEROBIC INTERVAL TRAINING

WALLNER, D.1, SIMI, H.1, ZLÖBL, T.1, GRUBER, A.1, HOFMANN, P.2

1: FH JOANNEUM UNIV. APPL. SCI. 2: KARL-FRANZ-UNIV. AND MED. UNIV. GRAZ

Training at high running speed improves running economy but yields no effect when training is performed highly anaerobic too frequently (Billat et al., 1999). Intensive aerobic interval training (IAEIT) results in accumulated high running speed with only a small contribution of anaerobic glycolytic energy supply (Christmass et al., 1999). Aim of the study was to analyse the response of heart rate (HR), blood lactate concentration (La) and oxygen uptake (VO<sub>2</sub>) to IAEIT of different running speeds. Only a slight contribution of anaerobic glycolytic energy supply was aimed to mimic the characteristics of slow continuous runs. **Method:** Eight trained male runners (VO<sub>2</sub>max:  $55.5 \pm 3.3$  ml/kg/min) participated in the study. They performed an incremental exercise test (increments: 0.75 km/h very minute) and three randomly assigned IAEIT of 30 min on a treadmill. In SAET work periods of 10 s were separated by 20 s of passive rest. Running speed of work periods was set to gain a mean running speed of 50%, 55% and 60% of velocity at the first lactate turn point (vLTP1). HR and VO<sub>2</sub> were measured continuously. La was analysed every minute during the first 10 min and subsequently every 5 min till the end of IAEIT. For warm up a slow continuous run was performed for 10 min at 0.5 km/h below vLTP1 in all tests. **Results:** Mean running speed at LTP1 and velocity at VO<sub>2</sub>max (vVO<sub>2</sub>max) was  $12.3 \pm 0.4$  km/h and  $19.8 \pm 0.9$  km/h. Running speed of work periods was  $18.7 \pm 0.7$  km/h,  $20.2 \pm 0.6$  km/h and  $22.3 \pm 0.7$  km/h for the different IAEIT. There was no significant difference between vVO<sub>2</sub>max and running speed of work periods at 55%vLTP1. Significant differences were found for HR, La und VO<sub>2</sub> between all three IAEIT ( $p < 0.01$ ). The different IAEIT intensities resulted in La of  $1.09 \pm 0.31$  mmol/l,  $1.57 \pm 0.52$  mmol/l and  $2.09 \pm 0.99$  mmol/l, respectively. La at 50%vLTP1 showed no significant difference to La at the end of warm up and vLTP1 ( $p > 0.05$ ). Depending on IAEIT intensity, VO<sub>2</sub> reaches 71.1%, 80.4% and 85.6% of VO<sub>2</sub>max at the end of very work period. Mean VO<sub>2</sub> was 54.0%, 58.5% and 64.0%, respectively. **Conclusion:** In IAEIT with work periods of 10 s separated by 20 s of passive rest and a mean running speed of 50%vLTP1 gave an overall aerobic metabolism similar to slow continuous runs despite almost maximal aerobic running speed during work periods. **References:** Billat et al. BERGEN UNIVERSITY COLLEGE, BERGEN; NORWAY; NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY, TRONDHEIM, NORWAY

**Introduction** Low cadence interval training is a common training method for cyclists. The effect of low cadence training on endurance-performance, and muscle strength is to our knowledge, not investigated. Some studies indicate that the freely chosen cadence (FCC) is decreased and efficiency is increased after strength training. The aim of the present study was to investigate the effects of low cadence training in on freely chosen frequency and gross efficiency during sub-maximal and maximal cycling **Methods** Twenty four highly trained male cyclists' with a VO<sub>2</sub>max  $59.1$  ml·kg<sup>-1</sup>·min<sup>-1</sup> volunteered in the present study. Subjects were randomised into one low cadence training group (Lctg) and one control training group (Ctg). Low cadence training was performed as 5 x 6 min work periods at 40 RPM between 72-82 %HRmax and was performed twice a week for 12 weeks in addition to their usual training programme. Ctg performed their usual training programme and in addition an equal amount of extra training (at FCC) per week as Lctg with a heart rate of 72-82 % of HRmax. At pre and post-test 5 sub-maximal work rates, a 30 minutes time-trial test was performed using a Velotron ergometer (DynaFit Pro, Racermate, USA) in addition to measurements of maximal leg strength. Oxygen consumption was measured using a Jaeger Oxycon Pro in mixing chamber mode (Jaeger, Germany). Gross efficiency was calculated as the ratio between external work rate and metabolic rate. **Results** There were no significant improvements in maximal leg strength in any of the groups. At the 30 min time-trial test average FCC was 100.3 RPM and gross efficiency was 20.0 % at an average work rate of 284 W. By the use of this test, there was no significant change in FCC or gross efficiency. At the sub-maximal workloads, average FCC was 94.7 RPM (stable with increased work rate) and gross efficiency 19.7 % (increasing with increased work rate). Ctg significantly increased FCC from 94.2 RPM to 95.2 RPM and the

gross efficiency was decreased from 19.9 % to 19.6 %. Lctg showed no significant changes. Discussion The present study demonstrates that 12 weeks of low cadence cycling seems to have no effect on FCC or gross efficiency during submaximal cycling and during a 30 min time-trial test. The same training load performed at FCC seems to increase FCC and decrease gross efficiency during sub-maximal cycling which might be negative over long distances. Thus, low cadence training might prevent an energy consuming higher FCC over time in the training process and energy saving results over time compared to only FCC training.

#### FAT OXIDATION RESPONSES TO HIGH-INTENSITY AEROBIC EXERCISE IN ADULTS.

STOA, E.M., HELGERUD, J., SVELA, B., STORLI, E., KITILSEN, H.T., ERIKSEN, K., STØREN, Ø.

Introduction: Intensity is an important factor when considering the dose of aerobic physical activity required for gaining a certain health benefit. The purpose of this study was to investigate what effects high intensity aerobic training (HIT) have on maximal oxygen uptake (VO<sub>2</sub>max), total energy expenditure during 30 min at 70% VO<sub>2</sub>max (kcal/30min), fat oxidation (fatox) at 70% VO<sub>2</sub>max and percent body fat (fat%) in adults. The results are presented as preliminary data, as the testing of a control group is in progress. Methods: 9 individuals (age: 44 ± 12, VO<sub>2</sub>peak: 2.98 ± 0.73 L · min<sup>-1</sup>, BMI: 27.3 ± 3.0) volunteered for this study. All subjects were approved to participate in the study after a medical examination. The subjects agreed not to change their diet habits, and the diet was registered before and during the intervention period. The HIT protocol consisted of 4x4 min cycling workouts at intensity between 90-95% Hfmax 3 times per week for 6 weeks. The following pre- and post tests were performed; anthropometrics (weight, height, BMI, body fat percentage), blood samples (blood lipid profiles), and measurements of HR and VO<sub>2</sub> in sub maximal and maximal tests. All physical tests were carried out using a test bike ergometer. The first test was a graded exercise test consisting of 3 x 5 min at a submaximal intensity with increasing workloads for each period. Immediately after this test, a VO<sub>2</sub>peak test was performed using an incremental protocol. After 1 hour of rest the subjects completed 30 min cycling at 70% VO<sub>2</sub>peak, where fatox was measured using indirect calorimetry. Results: After 6 weeks of HIT the subjects had increased their VO<sub>2</sub>peak (9.4%), kcal/30min (6.9%) and fatox (15.6%). Fat% was decreased (8.6%) and bodyweight was unchanged. Practical applications: An important issue in health related research is how physical activity can give health benefits. The results in this study indicate that the effects of training can be influenced by the intensity of work. Further research about more precise intensity-response relationship for a number of specific health outcomes is needed. Whole-body fat oxidation determined by graded exercise and indirect calorimetry: a role for muscle oxidative capacity? *Scand J Med Sci Sports.* 2006 Jun;16(3):209-14.

#### EFFECTS OF LOW CADENCE INTERVAL TRAINING IN CYCLING

KRISTOFFERSEN, M.1, LEIRDAL, S.2, IVERSEN, V.V.1

BERGEN UNIVERSITY OG COLLEGE

Introduction Low cadence interval training (40-60 RPM at 72-82 %HRmax) is a common training method for cyclists. The effect of low cadence training on endurance-performance, and muscle strength is to our knowledge, not investigated. The aim of the present study was to investigate the effects of low cadence training in highly trained veteran cyclists on 30 min cycling performance, lactate threshold, VO<sub>2</sub>max and muscle strength. Methods Twenty four highly trained male cyclists age 47.1 ± 5.9 years with a VO<sub>2</sub>max 59.1 ± 4.03 ml·kg<sup>-1</sup>·min<sup>-1</sup> volunteered in the present study. A pre-to post-test experimental design was applied, with a twelve week training intervention. The subjects were randomised into two groups, one low cadence training group (Lctg) and one control training group (Ctg). For the Lctg group, low cadence training was performed as 5 intervals of 6 minutes work periods at 40 RPM and between 72-82 %HRmax, which was performed twice a week in addition to their usual training programme. The Ctg group performed their usual training programme and in addition an equal amount of extra training (at freely chosen cadence) per week as the Lctg with a heart rate of 72-82 % of HRmax. At pre and post-tests; VO<sub>2</sub>max, lactate threshold, 30 minutes time-trial test and maximal leg strength, was tested. Tests were performed on a Velotron bike (DynaFit Pro, Racermate USA). Heart rate was measured using a Polar RS 800 CX, (Kempele, Finland). Oxygen consumption was measured using a Jaeger Oxycon Pro in mixing chamber mode (Jaeger, Germany). Lactate was measured using a Lactate Scout (Biosen, Germany) device. Results There were no significant improvements in maximal leg strength. The Ctg had a significantly improvement in VO<sub>2</sub>max, lactate threshold work rate and VO<sub>2</sub>. The 30 minutes maximal cycling test revealed that the Ctg increased the average performance significantly from 278 W to 295 W and the VO<sub>2</sub> utilisation during this test from 52.8 to 54.7 ml·kg<sup>-1</sup>·min<sup>-1</sup>. Thus, the Lctg group showed no effect of the training period on any parameter. Discussion The present study demonstrates that 12 weeks of low cadence cycling seems to have no effect on 30 min maximal cycling, VO<sub>2</sub>max, lactate threshold or muscle strength. In fact, an equal amount x intensity (training load) of endurance training at freely chosen cadence seems to have more beneficial effects on VO<sub>2</sub>max, lactate threshold parameters and a 30 min time-trial performance test. The higher muscular forces during low cadence training might be fatiguing and negative for the quality of the endurance training at higher intensities.

#### EFFECT OF INTENSE INTERVAL TRAINING ON BLOOD PRESSURE AND HEMODYNAMICS IN SUBJECTS WITH ESSENTIAL HYPERTENSION

JENSEN, G.L.1, NYBERG, M.1, THANING, P.2, HELLSTEN, Y.1, MORTENSEN, S.P.2

1:UNIVERSITY OF COPENHAGEN, 2:RIGSHOSPITALET

Introduction Roughly 1 billion people worldwide suffer from hypertension and extensive work has been done to evaluate pharmacological and non-pharmacological interventions. Regular physical activity of moderate intensity is known to reduce blood pressure but the effect of high intensity intermittent exercise on blood pressure is less clear. Moreover, the mechanisms behind the blood pressure lowering effects of exercise remain unsolved. Nitric oxide (NO) and vasodilator prostanoids (PGs) are potent vasodilators that contribute to blood pressure regulation. The present study examined the effect of intensive interval training on blood pressure and the role of the NO/PG system in this response. Methods Ten subjects diagnosed with essential hypertension (47±4 years, 171±11 cm, 80±24 kg (S.E.)) and ten normotensive control subjects (46±3 years, 177±8 cm, 76±9 kg), performed 8 weeks of high intensity intermittent exercise training (1 hour cycling sessions 3-4 times per week, ~40% of training time > 80% of heart ratemax). Before and after the training period, the subjects participated in an experiment in which intra-vascular blood pressure and leg hemodynamics were measured at rest and during low, medium and high intensity one-leg knee-extensor exercise. The measurements were performed with and without inhibition of NO and

PGs by infusion of L-NMMA and Indomethacin into the femoral artery. Results Training increased ( $P<0.05$ )  $\text{VO}_2\text{max}$  by  $\sim 10\%$  in both groups and decreased ( $P<0.05$ ) mean arterial pressure by 7 mmHg in the hypertensive group only. The reduction in blood pressure was present both at rest and during all exercise intensities. Blocking the NO/PG system fully reversed the training induced reduction in resting and exercising blood pressure. Discussion The finding of a reduction in blood pressure in individuals with essential hypertension highlights that high intensity interval training is an efficient non-pharmacological intervention. The finding of full reversal of the blood pressure reduction by NO and PG blockade strongly indicates that one or both of these systems is up regulated with training in hypertensive subjects and contribute to the training-induced reduction in blood pressure. ## **PRACTICAL MODELS OF HIGH-INTENSITY INTERMITTENT EXERCISE DESIGNED TO DECREASE MUSCLE GLYCOGEN LEVEL**

SHIOSE, K., TOBINA, T., FUJI, T., WADA, H., HIGAKI, Y., KIYONAGA, A., TANAKA, H.

FUKUOKA UNIVERSITY

**Introduction** The decrease of muscle glycogen contributes to subsequent glycogen supercompensation and enhances exercise-induced gene expression involved with mitochondrial biogenesis. Since reduced muscle glycogen may contribute to the improvement of endurance performance, it is important to establish a simple method for achieving a low muscle glycogen level. Muscle glycogen decrease per unit time was greater in consecutive intense exercise bouts (e.g. repeated Wingate test) compared with low-intensity continuous exercise (LCE). However, because the Wingate test requires extreme physical exertion, such a protocol is difficult to complete, even for athletes. The purpose of this study was to examine the degree of glycogen decrease and physical demand in several practical models of high-intensity intermittent exercise (HIE). **Methods** Nine young subjects participated in three experimental sessions conducted in random order. In two of these sessions, the subjects performed HIE. One of the HIE sessions consisted of 60-second cycling bouts at  $\text{VO}_2\text{max}$  (HIE\_  $\text{VO}_2\text{max}$ ) and another session consisted 75-second cycling bouts at 80%  $\text{VO}_2\text{max}$  (HIE\_80% $\text{VO}_2\text{max}$ ). In both sessions, 12 bouts of exercise were completed with a 4-minute rest between each bout. In the last session, subjects performed LCE, cycling at lactate threshold. The exercise duration of the LCE session was adjusted to match the total work performed during the HIE sessions. Heart rate (HR) was measured during all experiments. The RPE and blood lactate concentration were measured after each bout. To assess muscle glycogen content, muscle biopsies were obtained from vastus lateralis muscle before and after experimental sessions. Result Muscle glycogen decrease was greatest during HIE\_  $\text{VO}_2\text{max}$  ( $57.9 \pm 15.9\%$ ), followed by the HIE\_80% $\text{VO}_2\text{max}$  ( $43.0 \pm 7.4\%$ ), and finally, LCE ( $22.4 \pm 20.4\%$ ). Both HIE protocols were significantly superior to LCE in reducing muscle glycogen ( $p<0.05$ ), but were not different from each other. Blood lactate concentration after each session was highest during HIE\_  $\text{VO}_2\text{max}$ , followed by HIE\_80% $\text{VO}_2\text{max}$ , and finally, LCE ( $7.2 \pm 1.1$ ,  $3.9 \pm 0.9$ ,  $1.1 \pm 0.3$  mmol/L, respectively;  $p<0.05$  for all comparisons). RPE ranged between 13–16 during the HIE\_  $\text{VO}_2\text{max}$  and 11–14 during the HIE\_80% $\text{VO}_2\text{max}$ , while maximal HR corresponded to 79.5 and 71.3% of HR reserve, respectively. **Discussion** The muscle glycogen level after both HIT protocols was similar to that reported after consecutive Wingate tests in previous studies. Thus, both HIE protocols may be effective at decreasing muscle glycogen level. The HR and RPE data during exercise suggest that both HIE protocols may be less strenuous compared with a repeated Wingate test. **In conclusion**, HIE\_  $\text{VO}_2\text{max}$  and HIE\_80% $\text{VO}_2\text{max}$  are practical models of high-intensity intermittent exercise that can decrease muscle glycogen level.

#### **VARIATION OF INTRAOCULAR PRESSURE UNDER TWO DIFFERENT INTENSITIES AND VOLUMES OF RESISTANCE TRAINING**

MARCELO, C., MOREIRA, C., SCARPI, M.J.

FEDERAL UNIVERSITY OF SÃO PAULO

**Introduction** The association between Intraocular Pressure (IOP) and Physical Exercise has been discussed for several years. However, few studies have been conducted regarding to the association between IOP and Resistance Training (RT). Therefore, the aim of this study was to verify the influence of two different intensities and volumes of resistance training on IOP. **Methods** A population of 19 volunteers ( $21.8 \pm 3.28$  years old) who were athletes and practiced boxing, underwent to two different RT sessions: (S1) 3 sets of 15 repetitions with 60% of one repetition maximum (1RM) using an interval of 30 seconds between the sets, and (S2) 4 sets of 8 repetitions with 80% of 1RM using an interval of 120 seconds between the sets. The IOP measurement was taken by Perkins tonometer before, during and after the RT sessions. All data were described by descriptive tests. The statistical analyses were performed by Shapiro-Wilk Test and ANOVA with Tukey post-test. **Results** There was a reduction in IOP during both RT sessions. However, S1 had a significant reduction in IOP when compared with S2. At the end of session IOP returned to the initial scores, in both sessions. **Discussion** According to metabolic pathway for performing the exercises, it is suggested that in S1 there is greater involvement of the glycolytic metabolism for energy demand due to higher number of repetitions associated with the short time interval between the sets. Whereas, in S2, almost producing energy is of the phosphogen system, due to the short duration of the exercise and long period of recovery of interval between sets. Due to the exercise conditions in S1, there was a higher lactate production than in S2. The increase of lactate and consequent reduction in blood pH has been considered one of the main factors associated with the IOP reduction in anaerobic exercises. Thus, a RT session performed with lower intensity and higher volume can promote greater reduction in IOP. **References** American College of Sports and Medicine. **VENTILATORY RESPONSE DURING REPETITION OF SHORT-TERM MAXIMAL EXERCISE**

YAMANAKA, R., YUNOKI, T., ARIMITSU, T., AFROUNDEH, R., LIAN, C.S., MATSUURA, R., YANO, T.

HOKKAIDO UNIVERSITY

Ventilatory response during repetition of short-term maximal exercise Yamanaka R. 1, Yunoki T. 1, Arimitsu T. 1, Afroundeh R. 1, Lian C.S. 1, Matsuura R.2, Yano T. 1 1: Hokkaido University (Sapporo, Japan), 2: Kyushu Kyoritsu University (Kitakyushu, Japan) Introduction Ventilation (VE) increases during intense exercise and remains at a higher level than the pre-exercise value for a period of more than 10 min during recovery from exercise. The increase in VE during and after intense exercise is considered to be a homeostatic function for compensation of acidosis (decline in pH) induced by exercise. Although the decline in pH itself is known to be one of the factors driving breathing, the effect of pH on the ventilatory response during and after short-term maximal exercise (SME) remains unclear. Therefore, in the present study, to determine the effect of pH on the ventilatory response during and after SME, we examined the ventilatory response during and after repeated SME in which the increase in lactate and consequently the decline in pH are attenuated with decrease in muscle glycogen content. Methods Eight subjects performed three SME tests that consisted of SME (100-105%  $\dot{V}O_{2peak}$ -work rate, 120 sec) using a cycle ergometer and subsequent 20 min of recovery. Between SME tests, the subjects also performed 40 min of moderate intensity exercise (ventilatory threshold) with a subsequent 40-60-min period of recovery. Results At the end of SME and during subsequent recovery, blood pH was significantly higher in the 3rd test than in the 1st test. VE during SME and the first 60 sec of recovery was increased by repetition of SME, and VE in the 3rd test was significantly higher than that in the 1st test. During recovery after the first 60 sec, there were no significant differences in VE between the tests. Perceived exertion of legs (PEL) during SME was increased by repetition of SME, and PEL in the 3rd test was significantly higher than that in the 1st and 2nd tests. Although perceived exertion of the whole body tended to be higher in the 3rd test than that in the 1st test at 3 min and 10 min of recovery, there were no significant differences throughout the recovery period. Integrated EMG (IEMG) in the vastus lateralis (VL) during SME was significantly lower in the 3rd test than in the 1st test. MPF of the EMG in the VL during SME was significantly higher in the 2nd and 3rd tests than in the 1st test. Discussion Although the decline in blood pH was attenuated, VE increased with an increase in PEL by repetition of SME, suggesting that VE during SME is affected by PEL rather than by blood pH. Moreover, the increase in recruitment of type II fibers during SME, which was estimated from the increase in MPF of the EMG, could increase VE via a central mechanism that is associated with perceived exertion other than general central command (IEMG). However, VE during the recovery period except for the first 60 sec did not seem to be related to blood pH and perceived exertion.

**SHORT TERM TREADMILL RUNNING ENHANCE BRAIN PLASTICITY**

YANAGITA, S.1, KANEMARU, J.2, OCHIAI, H.2, UMEZAWA, M.2, TAKEDA, K.2

TOKYO UNIVERSITY OF SCIENCE

Introduction It is well known that physical exercise has an important role for improvement of brain functions, such as mental states and cognitions. Because several studies have reported that alteration of brain functions are closely related to the neuronal plasticity, physical exercise may induce enhancement of brain functions via induction of neuronal plastic changes. However, little is known about the relationship between physical exercise and brain plasticity. In this study, we examine the effects of short term treadmill running on expression of  $\Delta$ FosB protein, which is known to mediate neuronal plasticity, in rats. Materials and Methods Male Wistar rats were used in this study. The rats performed low intensity treadmill running for 30mins per day during 1 day, 3, or 5 straight days. Running speeds were progressively increased from 15m/min to 20m/min. Control rats were placed on non-driven treadmill on equal durations with treadmill running group. We assessed the expression of  $\Delta$ FosB using immunohistochemistry in various brain regions. Results Two way ANOVA revealed the significant main effects for the number of  $\Delta$ FosB expression in striatum between control and treadmill running. Multiple comparison showed that 3days treadmill running induced a significant increase in the number of  $\Delta$ FosB positive cells in the striatum, which have important role for motor activity, compared to that in 1 day treadmill running ( $P < 0.05$ ). 5 days treadmill running also significantly increase  $\Delta$ FosB expression in striatum compared to 1 day, but not 3days treadmill running. Two way ANOVA revealed the significant main effects for the number of  $\Delta$ FosB expression in hippocampus between control and treadmill running. The expression of  $\Delta$ FosB in hippocampus in rats performed treadmill running were significantly higher than that in control rats in all exercise duration. Treadmill running during 5days induced a significant increase in the number of  $\Delta$ FosB positive cells in the hippocampus compared to 1 day and 3 days treadmill running. Discussion The results of the present study showed that treadmill running enhance  $\Delta$ FosB expression in striatum and hippocampus in despite of relatively short exercise duration. The increasing levels of  $\Delta$ FosB with repeated stimulation would result in the gradual induction of significant levels of a long-lasting AP-1 complex, which is hypothesized to underlie persisting forms of neuronal plasticity in the brain. Taken together with the results of this study, it is suggested that even short term physical exercise could improve brain functions via increasing neuronal plasticity, and that  $\Delta$ FosB may play a key role in controlling physical exercise-induced neuronal plasticity in the brain.

**DOES EXERCISE INTENSITY ALONE PROMOTE RUNNING-INDUCED INCREASES IN MUSCLE SPECIFIC CALPAIN-LIKE ACTIVITY AND INDICES OF MUSCLE INJURY?**

BELCASTRO, A.

YORK UNIVERSITY

Introduction Despite the link between increased muscle calpain activity and indices of muscle damage with exercise; controversy exists as to which exercise factor(s) may be important in mediating this relationship. Exercise intensity is considered the primary factor in inducing the "calcium-calpain and muscle damage" relationship. Whether total energy expenditure and specific muscles also contribute to the exercise response is not in the literature. The purpose of this study was to determine the effect of low and high energy expenditures at three exercise intensities on rat plasma CK, and muscle activities of calpain-like protease and myeloperoxidase. Methods Male rats ( $306 \pm 24$ g) were assigned to a control and six run exercise groups; each having a different intensity (15m/min, 25m/min and 35m/min) and equated to two different energy expenditure (EE) levels (high or low). Following exercise, muscle calpain-like and myeloperoxidase activities were assayed for soleus (S), plantaris (PL), and v. lateralis (VL) muscles. Blood creatine kinase (CK) activity was also assessed post-exercise. Results Blood CK and muscle protease activities on average increased in a dose-dependent manner in response to intensity ( $r^2 = 0.66$ ), with calpain-like activities being muscle specific. PL calpain-like activities increased ( $p < 0.05$ ) from  $14.1 \pm 4.2$  to  $22.5 \pm 5.5$  U/g wet wt for the 15 m/min group, while the 25 m/min group went from  $17.6 \pm 4.4$  to  $33.8 \pm 7.2$  U/g wet wt ( $p < 0.05$ ). Comparable results were found with the vastus lateralis muscles. In contrast, the responses to EE varied with PL having larger (33%) increase to HEE, while the response for VL was greater to LEE (44%). The S did not respond to exercise conditions in any systematic manner ( $p > 0.05$ ). Discussion

Skeletal muscle protease (calpain-like) activity increased with exercise: a) at both EE but the magnitude of the response at LEE and HEE was muscle specific; and b) at all intensities with  $PL > VL > S$ . Skeletal muscle protease activity and plasma creatine kinase activity were positively related across all energy expenditure and exercise intensities. Skeletal muscle protease and myeloperoxidase activities were generally not related across all energy expenditure and exercise intensities, although responses were muscle specific  $VL > PL > S$ . In summary, any studies examining the "calcium-calpain and damage" framework must consider not only the intensity of the loading but also its EE before definitive conclusions about the relationship between muscle protease activity and muscle damage can be offered. Supported by NSERC Canada

### EXERCISE INFLUENCE ON THE AMPHETAMINE-DEPENDENT BEHAVIOUR AND DOPAMINE IN STRIATUM, FRONTAL CORTEX AND HIPPOCAMPUS

FONTES RIBEIRO, C., PEREIRA, F.C., SILVA, A.P.

FACULTY OF MEDICINE OF THE UNIVERSITY OF COIMBRA

**Introduction** The dopaminergic mesocorticolimbic and nigrostriatal systems are considered to be involved in drug addiction. However, there is little information about the effect of exercise on addiction and on the synthesis, metabolism and action of dopamine (DA) in the central nervous system, in the presence of amphetamines (Marques et al., 2008). Therefore, this work aimed to verify the influence of exercise on addiction using an amphetamine (AMPH)-induced conditioned place-preference (CPP) in rats, and to determine DA and respective metabolites (DOPAC, HVA) in striatum, frontal cortex and hippocampus. **Methods** Adult male Sprague-Dawley rats were randomly separated in two groups: one with and another without exercise, which consisted in a 8 weeks running program in a treadmill, with increasing intensity. The group with exercise trained 5 days per week, beginning with 6 cm/sec and finishing with 50 min (warming + 45 min at 54 cm/sec and 15% of slope). The CPP test was performed in both groups using the procedure and apparatus previously described. There were three phases: 1st phase - Pre-conditioning: free access to both compartments, 20 min sessions with registration of the time spent in each compartment; 2nd phase - Conditioning: 8 consecutive days (45 min sessions) in the alternated compartments (4 days of 2 mg/kg AMPH alternated with saline injections); 3rd phase - Test day: free access to both compartments, 20 min sessions with registration of the time spent in each compartment. Animals were sacrificed 24 h after the last AMPH or saline, and striatum, hippocampus and frontal cortex were dissected for DA and metabolites measurement by HPLC with coulometric detection. **Results** Since in the pre-conditioning phase none of the animals presented preference for a compartment, all the animals were used in the study. The group without exercise showed preference for the compartment associated with AMPH ( $p < 0.05$ ), being the opposite observed with the animals with exercise. In the striatum and frontal cortex, AMPH decreased DA content; training and AMPH reduced DA and metabolites, whereas training alone did not induce significant changes. However, training increased DA and metabolites in the hippocampus, inhibiting the AMPH-induced DA reduction. **Discussion** According to these results, chronic exercise may prevent the AMPH-seeking behaviour in this animal model but not significantly changes the impact of AMPH on striatal and frontal DA synthesis. Data also suggest that exercise may correlate with changes in DA dynamics in hippocampus. **References** Marques E, Vasconcelos F, Rolo M R, Pereira F C, Silva A P, Macedo TR, Ribeiro C F. (2008). *Ann N Y Acad Sci*, 1139, 222-231.

### INFLUENCE OF EXERCISE ORDER ON THE ACUTE HORMONAL RESPONSES TO CONCURRENT TRAINING

GORSKI, T.1, CADORE, E.L.2, DOS SANTOS, M.G.2, MARTINS, J.B.2, LHULLIER, F.L.R.2, PINTO, R.S.2, SILVA, R.F.2, KRUEL, L.F.M.2  
1:UNIVERSITY OF BERN (BERN, SWITZERLAND), 2:FEDERAL UNIVERSITY OF RIO GRANDE DO SUL (PORTO ALEGRE, BRAZIL)

**Introduction** Rises in the levels of circulating cortisol (COR) and the consequent imbalance in anabolic hormones due to large training volumes can produce an unfavorable environment for the development of muscle mass, becoming a cause for the interference effect of concurrent training (CT). This study analyses the influence of exercise type order on the acute response of total testosterone (TT) and COR during and after a CT session. **Methods** Ten strength-trained men ( $23.5 \pm 0.9$  years;  $174.8 \pm 4.9$ cm;  $77.5 \pm 4.8$ kg;  $15.8 \pm 2.7\%$  fat mass) randomly performed two different CT sessions separated by 1 week: aerobic exercise (AE) following strength exercise (SE) (SE-AE) or AE preceding SE (AE-SE). SE lasted about 30 minutes and consisted of three sets of eight repetitions at 70% of 1 maximal repetition (90s resting between sets) for four exercises: bench press, squat, lat pull down and knee extension. AE consisted of 30 minutes of continuous exercise on a cycle ergometer at 75% of maximal heart rate. Blood samples were obtained before (pre), in between AE and SE and after (post) the training sessions to determine TT and COR concentration. **Results** There were no significant differences in the TT and COR resting levels between the different experimental days. TT increased after the first exercise type in both exercise orders, but post-TT remained significantly higher than pre-TT only in AE-SE ( $P < 0.01$ ). The TT variation after the first exercise type was higher than the observed after the second (SE-AE: 22.3 vs. -12.9%; AE-SE: 31.8 vs. 7.6%;  $p < 0.05$ ) and TT total variation (after the CT session) was significantly higher in AE-SE than in SE-AE (41.4 vs. 3.3%;  $p < 0.01$ ). COR levels increased after the first exercise type and returned pre-levels after the second exercise type in both situations. No significant differences between exercise orders were found in total variation of COR (AE-SE: 12.6%; SE-AE: 8.2%) and the variation during the first exercise type was significantly higher than during the second (SE-AE: 10.6 vs. -2.1%; AE-SE: 11.5 vs. 1.1%;  $p < 0.05$ ). **Discussion** The results showed that the order in which the types of exercise are performed during a CT session can influence the acute testosterone response, with the AE-SE session showing a greater relative increase after the training session, which was not observed in COR. Based on the relationship between acute hormonal responses and chronic neuromuscular adaptations to strength training suggested in the literature, this could be positive for the optimization of muscle hypertrophy in the long term. However, the extent of the importance of this response in chronic adaptations to CT remains speculative.

### COMPARISON BETWEEN ENDURANCE AND STRENGTH EXERCISE EFFECTS ON TISSUE TRIGLYCERIDES IN RATS

ROSTOM DE MELLO, M.

SÃO PAULO STATE UNIVERSITY

**COMPARISON BETWEEN ENDURANCE AND STRENGTH EXERCISE EFFECTS ON TISSUE TRIGLYCERIDES IN RATS** MELLO, M.A.R., BOTEZELLI J.D., DALIA, R.A., GHEZZI, A.C., CAMBRI, L.T., MOURA, L.P. 1: UNESP (Rio Claro-Brazil) **Introduction** Physical exercise is a powerful weapon used to reduce adiposity in human beings and in rats (Gaesser; Brooks, 1975). However, few studies address the effects of different exercise protocols on tissue triglyceride content. The aim of this study is to analyze the effect of strength and endurance training on the triglyceride content in the liver and in the adipose tissue of different regions, in rats. **Method** Twenty four male Wistar (120 days old) rats were randomly separated into three groups with eight rats per group: C (control sedentary), S (strength exercise) and E (endurance exercise). The animals of E group performed a minimum lactate test (ML) (Voltarelli et al., 2002) to identify the individual aerobic/anaerobic metabolic

transition during swimming exercise and were subjected swimming endurance training at 80% of ML intensity, one hour/day, five days/week. The S group was subjected to a strength training protocol consisting in four series of 10 jumps in the water separated by 10 minutes of rest, five days/week (Rogatto et al.). The animals were trained during 7 weeks. At the end of the experiment, they were killed by sodium thiopental administration to evaluate the triglyceride content (mmol/mg) in the liver and in the mesenteric, retroperitoneal and subcutaneous adipose tissue (Nogueira et al., 1990). The results were statistically analyzed by one-way ANOVA and the significance level was set at  $p \leq 0.05$ . Results Liver triglyceride content was higher in E group compared to C group: C =  $6.4 \pm 1.9a$ , S =  $9.2 \pm 2.7ab$ , E =  $9.9 \pm 1.5b$ . Mesenteric triglyceride content was lower in E and S groups compared to C group: C =  $15.6 \pm 0.6a$ , S =  $11.9 \pm 1.2b$ , E =  $10.1 \pm 2.4b$ . Retroperitoneal triglyceride content was lower in E and S groups compared to C group: C =  $20.3 \pm 5.4a$ , S =  $11.1 \pm 2.1b$ , E =  $10.9 \pm 4.0b$ . Subcutaneous triglyceride content was lower in E and S groups compared to C group: C =  $28.4 \pm 5.9a$ , S =  $16.5 \pm 1.5b$ , E =  $16.7 \pm 2.0b$ . Different letters indicate statistical difference. Conclusion: Both exercise protocols had beneficial effects on fat tissue depots of rats, since they equally reduced the triglycerides content in the adipose tissue. However, rats trained by the endurance protocol showed high values of triglycerides in the liver. Further studies are required in order to understand the alterations imposed by different exercise protocols on body fat distribution. Support: Fapesp, CAPES and CNPq. ## ACUTE METABOLIC RESPONSES ASSOCIATED WITH STRENGTH AND HYPERTROPHY-TYPE WORKOUTS CORRECTED FOR PLASMA VOLUME CHANGES

NICHOLSON, G., ISPOGLOU, T., POLLITT, L., BISSAS, A.

LEEDS METROPOLITAN UNIVERSITY

Introduction Information on the acute metabolic responses to resistance exercise (RE) may provide valuable information regarding peripheral fatigue factors. However, most studies have examined a relatively narrow range of metabolic responses to different RE workouts. In addition, much of the research has not accounted for plasma volume (PV) changes. This study compared a wider profile of metabolic responses following strength (STR) and hypertrophy-type (HYP) back squat workouts, when corrected for PV changes. Methods Following one repetition maximum (1RM) testing, seven trained males ( $23.6 \pm 2.7$  years) completed a STR workout (4x6 repetitions, 85% 1RM, 5 min rest intervals), a HYP workout (4x10 repetitions, 70% 1RM, 1.5 min rest intervals) and a control condition (CON) in a randomised cross-over design separated by at least 48 hours. Capillary blood samples were taken pre- (-20min, -10min, 0min) and post-exercise (+0min, +10min, +60min) in order to measure concentration of blood lactate (BL), electrolytes, haemoglobin (Hb) and haematocrit (Hct). The samples were analysed using a blood gas CO-Oximeter and electrolyte analyser (GEM Premier 4000). Following calculation of PV changes from Hb and Hct, variables were corrected using the method of Kraemer & Brown (1986). A two-factor within subjects ANOVA was employed for statistical analysis. Results Average PV changes were  $-8.05 \pm (11.45\%)$ ,  $-8.02 \pm (6.54\%)$  and  $-3.32 \pm (6.97\%)$  for the STR, HYP and CON conditions respectively. Repeated contrast tests revealed a significantly ( $p < 0.05$ ) greater increase (at +0min) in BL concentration following the HYP condition ( $1.40 \pm 0.32$  mmol/L-1 to  $12.16 \pm 3.74$  mmol/L-1) than the STR ( $1.66 \pm 0.44$  mmol/L-1 to  $8.31 \pm 2.95$  mmol/L-1) or CON ( $1.55 \pm 0.80$  mmol/L-1 to  $1.15 \pm 0.59$  mmol/L-1) conditions, this was also evident at +10min. In addition, the HYP workout resulted in significantly greater ( $p < 0.05$ ) gains in sodium (10.96%), chloride (6.32%) and calcium (12.27%) at +0min than the CON condition. Discussion PV changes were similar to those reported previously following RE (Wallace et al. 1990). The significant increase in BL concentration following the HYP workout is consistent with previous observations (McCaulley et al. 2009); however, the novel finding was the increase in the concentration of a number of electrolytes following the HYP condition. In this respect, the data highlight the need to consider electrolyte responses for a better understanding of the peripheral fatigue factors and long-term changes associated with HYP workouts. ## ENERGY COST DURING LEG PRESS AND CURL SCOTT EXERCISES

MAGALHÃES, N.1, VENCESBRITO, A.1,2, BRITO, J.1,2

POLYTECHNIC INSTITUTE OF SANTARÉM - SPORT SCIENCES SCHOOL OF RIO MAIOR

Magalhães N.1; Vencesbrito A.1,2; Brito J.1,2 1 Sport Sciences Research Laboratory of Sport Sciences School of Rio Maior (Rio Maior, Portugal) 2 Center of Research in Sports, Health and Human Development (CIDESD, Vila Real, Portugal) Introduction Strength training has had an exponential increase in the number of practitioners. Consequently, it has become essential to research more about its physiological effects, since several scientific communities support the need for strength training to improve health and functional capacity. The aims of this study were to assess the energy cost (EC) in Leg Press (LP) and Curl Scott (CS) exercises through the relationship between oxygen consumption (VO<sub>2</sub>) and external load, and to determine the aerobic and anaerobic contribution for the intensities of 60% and 85% of 1 maximum repetition strength test (1RM). Methods Twelve trained subjects (6 male, 6 female mean  $\pm$  SD age  $24.67 \pm 3.55$  years, height  $1.68 \pm 0.09$  m, weight  $66.87 \pm 14.11$  kg) performed the LP and CS exercises for a 5-minute period at the intensities of 20%, 25%, 30% and 35% of 1RM. For the 60% and 85% of 1RM the subjects performed their maximum number of repetitions. VO<sub>2</sub> was assessed with a portable gas analyser and the maximum value of lactate post-exercise (Lacmax) at 60% and 85% 1RM was also determined. Equations to predict EC for both exercises were calculated using linear regression. Results EC can be estimated in CS and LP exercises, respectively, by the following equations:  $Y = 12.101 + 1.541X$ ,  $R = 0.617$ ,  $R^2 = 0.380$ ,  $S_{xy} = 4.52$ ;  $Y = 13.048 + 0.795X$ ,  $R = 0.636$ ,  $R^2 = 0.405$ ,  $S_{xy} = 4.24$ , where Y corresponds to VO<sub>2</sub> and X is the percentage of 1RM. The predicted EC for CS at 60% and 85% 1RM was 15.86 and 20.64 ml-1kg-1min-1, respectively, with an accumulated VO<sub>2</sub> (AcVO<sub>2</sub>) of 13.72 and 13.69 ml-1kg-1min-1, respectively. This corresponds to an anaerobic contribution of 13.4% and 33.6%, respectively. The predicted EC for the LP exercise at 60% and 85% 1RM was 32.43 and 43.70 ml-1kg-1min-1 with an AcVO<sub>2</sub> of 20.15 and 18.06 ml-1kg-1min-1, respectively. This corresponds to an aerobic contribution of 37.8% and 58.4%, respectively. There was a significant difference in Lacmax between both exercises and between the different intensities, but no significant relationship between defO<sub>2</sub> and Lacmax were verified. Discussion The results imply that this method of extrapolation has the tendency to indicate higher EC values than those actually measured. However, there are some possible limitations due to the lack of linearity between work and VO<sub>2</sub> at higher intensities, in the repetition rate of each subject, which fatigue may alter (Robergs et al. 2007). It was also observed that the subjects would hold their breath while performing the exercises at the highest loads (mainly at 85% of 1RM), which may consequently alter the data collected by the gas analyser. **AEROBIC WORK CAPACITY IN JAPANESE MIDDLE-AGED RECREATIONAL CYCLISTS**

NAKAGATA, T., MURADE, S., ISHIHARA, Y., KATAMOTO, S., NAITO, H.

JUNTENDO UNIVERSITY

**Introduction** Recently, the recreational cycling becomes increasingly popular to prevent to lifestyle related disease such as diabetes and improve physical fitness in Japan. Cycling is one of the representative non-impact type exercise, and many people can cycle over prolonged duration irrespective of age and sex. However, the available data of the aerobic work capacity in Japanese recreational cyclists are only few. Therefore, we aimed to clarify the aerobic work capacity of Japanese middle-aged recreational cyclists. **Methods** Subjects were thirty-three healthy Japanese recreational cyclists aged 18-63 years old (29 males and 4 females). They usually enjoyed cycling 2-3 days/week over 120-240 km/week. Age and physical characteristics of male and female subjects were  $42.8 \pm 11.1$  and  $38.0 \pm 10.3$  yr,  $171.8 \pm 4.7$  and  $154.7 \pm 5.9$  cm,  $64.9 \pm 6.7$  and  $48.0 \pm 4.7$  kg, respectively. The male subjects were divided into 4 groups by ages; less than 30yr (U30, n=4), 30-39 yr (30G, n=5), 40-49 yr (40G, n=12), above 50 yr (50G, n=8). They performed a maximal exercise test using a cycle ergometer at 60 rpm. During the exercise test, heart rate (HR), oxygen uptake (Vo2) and blood lactate (La) were measured. Vo2 peak obtained individual during the exercise test was considered as Vo2 max. **Results** The mean Vo2max and HRmax of male and female subjects were  $52.1 \pm 7.2$  and  $46.5 \pm 4.8$  ml  $\cdot$  kg $^{-1}$   $\cdot$  min $^{-1}$ ,  $185 \pm 10$  and  $183 \pm 9$  bpm respectively, and declined with aging (56.6, 54.2, 51.3, 49.7 ml  $\cdot$  kg $^{-1}$   $\cdot$  min $^{-1}$  and 194.8, 191.0, 185.3, 177.5 bpm for each group). Vo2 at lactate threshold (LT) was also declined with aging (34.8, 30.7, 30.6, 30.7, 28.3 ml  $\cdot$  kg $^{-1}$   $\cdot$  min $^{-1}$ ), but there was no age-related changes in %Vo2max at LT (60.7, 56.5, 59.1, 61.2, 60.3%). **Discussion** Previous studies demonstrated that Vo2max declines with aging and the lack of physical activity. In this study, however, Vo2max of 40G and 50G was 38.5 % higher compared with the reference values that of age-matched Japanese people<sup>1)</sup> and the same level as joggers in 40-60yr<sup>2)</sup>. Vo2 at LT was 63 % higher than that of sedentary Japanese in 50yr and equivalent to joggers in 40-60yr<sup>2)</sup>. Especially, Vo2max and HRmax in 50G were comparable to that of Japanese adolescents on treadmill running. These results indicate that regularly cycling of 2-3 days/week over 120-240km in middle-aged men might stimulate their cardiorespiratory functions and contribute to improving their aerobic work capacity to higher level. **Reference** 1) Exercise and Physical Activity Reference for Health Promotion 2006 (EPAR2006) J Epidemiol. 17(5): 177, 2007 2) Takeshima, N et al. **Poster presentations****PP-PM76 Sports Medicine: Injury****DEVELOPMENT OF A METHOD OF MEASURING AMOUNT OF TAPE LOAD DURING SIDE-STEP AND LANDING MOVEMENTS**

ASHIHARA, M., WATANABE, H., FUJII, M., NSHIMURA, M., UCHIDA, Y., TAKAHIRA, N.

GRADUATE SCHOOL OF MEDICAL SCIENCE, KITASATO UNIVERSITY

**Introduction** Taping is a common practice to prevent sports injuries. Although there have been several studies done on taping, a method to quantitatively measure the effect of ankle taping during sports tasks remains not to be established. The purpose of this study was to develop a method of measuring the amount of mechanical load on one stirrup tape strip for braking foot inversion during side-step and landing movements, and to evaluate the usefulness of this method. **Methods** The subjects were 5 basketball players, who had on average 9.2 years' experience. For the measurement protocol, a KFG5-120 strain gauge (Kyowa Electronic Instruments Inc.) was bonded to 38 mm widths of white tape (Johnson & Johnson Inc.). One calibrated tape strip was applied to the player's lower limb, opposite the dominant leg, passing over each center of the lateral and medial malleoli as stirrup tape. For the sports tasks, side-step and landing movements were selected because they are responsible for 30% and 45% of ankle injuries, respectively. The players carried out the side-step, plus a 3 m run-up and lateral landing from 20 cm in height on a force plate (AMT Inc.). The force plate and strain force on the taping were set to a sampling frequency of 1000 Hz. The timing for the tape strip during sports tasks was identified from the phase of ground reaction force in a horizontal direction, as measured using a force plate. **Results** The amount of tape load while winding the tape strip on the lower limb reached a maximum force of 6.4 (4.8-10.7) kg, and then stabilized at 3.5 (2.9-5.0) kg. The tape load during the side-step was 5.3 (2.8-10.1) kg. The tape strip was timed as working 0.017 (-0.005-0.074) seconds later than the ground reaction force in a horizontal direction. The amount of tape load during lateral landing was 4.3 (2.0-9.2) kg. The tape strip was timed as working 0.017 (-0.246-0.148) seconds sooner than the ground reaction force in a horizontal direction. **Discussion** This study measured the amount of mechanical load on one stirrup tape strip during sports tasks. The timing of the tape strip working during sports tasks followed the phase of ground reaction force in a horizontal direction. Therefore, this method should prove useful as a method for measuring the amount of mechanical tape load. In further studies we hope to measure the braking force and the sustaining force during appropriate ankle taping using this method. It is thought that this will help to develop an effective taping method for the prevention of ankle inversion sprains in sports activities.

**COMPARISON OF PRE AND POST EXERCISE ANTERIOR TIBIAL COMPARTMENT PRESSURES ON NATURAL GRASS AND ASPHALT**

PERISSIOU, M.1, PRIONAS, G.1, KARAGOUNIS, P.1, ARMENIS, E.1, KARAMANIS, E.1, PEFANIS, N.1, FLESSAS, K.1, BALTOPOULOS, P.1, TSIRONI, M.2

FACULTY OF PHYSICAL EDUCATION AND SPORT SCIENCE, LABORATORY OF FUNCTIONAL ANATOMY AND SPORTS MEDICINE

**Introduction** Different running terrains seem to have an influence on the prevalence of developing musculoskeletal injuries. Previous experimental studies have attempted to examine the type of surface, its impact on the locomotor system correlated to the type and incidence of injuries, without being conclusive so far. Comparison of the pre- and post- exercise anterior tibial compartment pressures in two different types of surface (natural grass and asphalt) in asymptomatic recreational athletes. **Methods** Forty-five healthy male participants, aged 28  $\pm$  5 years old, with 5  $\pm$  2 years of running experience underwent the experimental procedures. The participants were evaluated before and immediately after a 5km distance, while running at 10 km/h for the whole distance. The speed was fixed because its control was essential for the reproducibility of the results. All participants were free from injuries of the lower leg for the last 12 months.

The athletic equipment was the same for every participant during the experimental procedures. Intra-compartment pressure measurements were recorded 1 minute before and at the first minute after the onset of exercise. The wick catheter technique was the method of choice for measuring intracompartmental pressure values. All pressure values were compared by ANOVA for repeated measures. Results Statistical analysis of the data indicated that all participants, both those on natural grass (pre- 8.17mmHg, post-15.4mmHg) as well as those on asphalt (pre- 8.75mmHg, post-18.3mmHg), presented statistically higher ( $p < 0.05$ ) intra-compartment pressures immediately after the completion of exercise respect to the values of the pre- exercise measurements. Special concern should be given on the participants exposed on the asphalt terrain where values of 18.3mmHg were recorded after the completion of the exercise, illustrating a statistical significant difference ( $p < 0.05$ ) compared to the values of those who exercised on natural grass. Discussion The results confirm that running on a rigid surface, such as asphalt, may be an additional factor of increased risk for presentation of pathological anterior tibial compartment values and possible exertional compartment syndrome (CECS) development. ### THE IMPACT OF TYPE OF GROUND ON POST-EXERCISE CPK LEVELS AND HEMATURIA IN ATHLETES

XIROUCHAKI, C.1, KARAGOUNIS, P.1, PRIONAS, G.1, ARMENIS, E.1, TRIANTAFILLOPOULOS, D.1, PRIFTIS, T.1, DOKA, V.1, BAL-TOPOULOS, P.1, TSIRONI, M.2

1: LABORATORY OF FUNCTIONAL ANATOMY AND SPORTS MEDICINE, UNIVERSITY OF ATHENS, GREECE 2: DEPARTMENT OF NURSING, UNIVERSITY OF PELOPONNESE, GREECE

Introduction Literature advocates that athletes present higher incidence of hematuria than general population. However, various parameters distinguish the sports related hematuria with one of those being the spontaneously resolve after physical exercise whereas hematuria in nonathletic general population is usually chronic. Exercise characteristics, such as exercise duration and most predominantly intensity influence exercise-induced hematuria. Increased body temperature, hemolysis, increased production of free radicals, and excessive release of catecholamines are among the mechanisms underlying the exercise induced hematuria. The aim of the current study was to investigate a) the impact of type of terrain (natural grass and asphalt) on post-exercise CPK levels and hematuria in recreational athletes, b) possible statistical significant correlation between post-exercise CPK levels and hematuria. Methods Thirty five healthy male recreational athletes aged  $23 \pm 4$  years were tested before, immediately after, and 1h after the completion of 5 km running on natural grass and asphalt. Participants were asked not to participate in any intense exercise 3 days before the experiment. Five days of rest separated the two experimental sessions. Participants ran a distance of 5 km at 10km/h. The speed was fixed because its control was essential for the reproducibility of the results. Blood samples were collected from an antecubital vein for creatine phosphokinase (CPK) determination. Hematuria, urinary pH, and proteinuria were measured by re-agent strips for urinalysis using an automated reagent strip analyzer. Urine that was positive for hematuria was centrifuged for 5 min at 1500 rpm before examination of RBC distribution. RBCs are commonly found in urine, however, three or more cells per high power field is considered unusual and is used as a marker of hematuria in the current study. Urine specimens of at least 10 ml each were collected 5 min pre-exercise, immediately after, and 1h post-exercise. The study employed a 3x2 (time by type of ground) within-subjects design for the statistical analysis. The level of significance for the multivariate analysis of variance (MANOVA) was set at  $P < 0.05$ . Results Natural grass running produced increased CPK levels in both post-exercise measurements (pre- 341 g/l, straight after 408g/l, 1h post 382 g/l). A significant part of the participants (12/35) presented sport hematuria. Asphalt running revealed higher CPK values in respect to those of natural grass running (pre- 348 g/l, straight after 458g/l, 1h post 394 g/l). Interestingly, correlation between CPK levels and hematuria prevalence became apparent after the post-exercise measurements. Discussion The results confirm that running on a rigid surface (asphalt) may be an additional factor of sport hematuria increased risk.

### SCREENING PARTICIPANTS FOR EXERCISE INDUCED BRONCHOSPASM PRIOR TO A PERFORMANCE RELATED STUDY

HU, J., DICKINSON, J., CHESTER, N., WHYTE, G.

LIVERPOOL JOHN MOORES UNIVERSITY

Background: Exercise induced bronchoconstriction (EIB) is defined as a bronchoconstriction occurring during or directly after exercise. Failure to recognize EIB amongst athletes is common (Dickinson et al., 2010). It therefore may be useful to screen potential participants for EIB, prior to them taking part in performance related studies. The aim of this study was to screen participants for EIB using the eucapnic voluntary hyperpnoea (EVH) challenge. Methods: A total of 69 participants were recruited (mean $\pm$ SD age  $22.84 \pm 4.51$  years, stature  $173.9 \pm 8.6$  cm, body mass  $71 \pm 9.1$  kg). They provided written informed consent. Each participant completed an EVH challenge test (Anderson et.al. 2001) involving 6 min hyperventilation at approximately 85% of maximal voluntary ventilation (30x baseline FEV1). Maximal flow volume loops were measured at baseline and at 3, 5, 7, 10 and 15min following completion of the challenge and a fall of 10% in FEV1 from baseline was deemed positive. An Independent T-test was conducted to compare FEV1 at baseline and maximal change following the EVH challenge between EVH-positive and EVH-negative participants. Significance was assumed if  $p < 0.05$ . Results: Nine (13%) of 69 participants presented EVH positive. There was no significant difference in baseline FEV1 between EVH negative and EVH positive subjects ( $4.0 \pm 0.9$  vs positive  $4.1 \pm 0.7$ ;  $p = 0.5$ ). However, there was a significant difference on largest FEV1 change and second largest FEV1 change between EVH negative and EVH positive participants ( $-5.6 \pm 2.7\%$  vs  $-18.7 \pm 6.7\%$ ;  $p < 0.01$ ) Conclusion: Thirteen percent of participants with no previous diagnosis of EIB tested positive using the EVH challenge test. The results indicate the prevalence of EVH positive participants is lower when compared to elite athletes (Dickinson et al. 2010). Screening volunteers prior to recruitment to intervention studies investigating exercise performance may be useful in eliminating EIB as a possible confounding variable. **INTRODUCTION** Sport can have betterment and remedy effect in patient , but sport activity may be come one of factor of causing illness or coarseness.Of course it happens in condition that sport techniques are performed in wrong shape and use from organs in non principle way and use more of body. **METHOD** for true gatering of information, has been used pusture screen, digital scale, tape line and podescope. And for gatering personal information and sport record used quationnair. for recognizing different and rudeness of spinal column and lower limb in man and woman kata and kumite pearson chi-square statical exame used 95% in certainly level that result of research is difference of incidence lordosis radeness between men kata and kumite athletes. **FINDINGS** The age, weight and tallness average of research is 1/70 cm. 67/67 kg and 22/36 age. That 41/3% activity in kata range and 58/7% in kumite range. For true gatering of information, has been used pusture screen, digital scale, tape line and podescope. And for gatering personal information and sport record used quationnair. For recognizing different and rudeness of spinal column and lower limb in man and woman kata and kumite Pearson chi-square statical exame used 95% in certainly level that result of research is difference of incidence lordosis radeness between men kata and kumite athletes. **DISCUSSION & RESULT** In incident of lordosis rudeness between kata and kumite athletes there is difference. In incident of Genu varum radeness there is difference between kata and women kumite athletes. In incident of kyphosis rudeness, scoliosis rudeness, Genu valgum, posture rudeness, Genu varum rudeness, there is no difference between men cata and kumitist. In incident of kyphosis rudeness, scoliosis rudeness, Genu valgum rudeness, there is no difference between woman cata and kumitist.So we must recognize causing of rudeness in cumite range that it may cause in contact of this range an anable in complete controlling of all techniques in training and match. By prevention of these we can help to athletes to be thrown away of sport accident of this range. **References** 1: Keith H. Brridwell T , Paul A. Anderson , Scott D. ### MULTISENSORY TRAINING PROGRAM REDUCES RISK OF INJURIES IN PROFESSIONAL FOOTBALLER

GENNARO, V., IODICE, P., DI PANCRAZIO, L., BELLOMO, R.G., SAGGINI, R.

UNIVERSITY OF CHIETI

**Introduction** There is evidence in literature suggesting that balance, agility and coordination training techniques can induce changes in lower-extremity muscle activity patterns that result in improvement in dynamic joint stability. The mechanoreceptors present in and around the joints are responsible for maintaining postural control and joint position sense. These receptors are integrated in order to compose the somatosensorial system. In combination with visual and auditory inputs, which improve our spatial perception even further, the systems are able to maintain a dynamic stable body posture. Increasing this ability is a concrete mean to the prevention of sport injuries. **Methods** 20 player professional footballers received 2 months of balance and postural training, 2 sessions per week, with the use of a multisensory training approach (I-moove), . Before and after the training program, and again 2 months later, subjects performed stabilometry test. At the same time, the isometric lower limb test was measured by dynamometer. The athletes' health condition was monitored all the season, injuries were registered and classified. **Results** Results show a decrease of sway area and ellipse surface. Muscular strength increase statistically correlated with equilibrium ability. **Discussion** The multisensory training approach, which reduces the risk of injuries, yields a balance improvement in athletes. **References** Bellomo RG, Iodice P, Savoia V, Saggini A, Vermiglio G, Saggini R. ### SPORTS INJURIES IN JAPANESE BLIND FOOTBALL PLAYERS

KINOSHITA, H.

TSUKUBA UNIVERSITY OF TECHNOLOGY

**Introduction** Blind football is an adaptation of football 5-a-side for athletes with visual impairments including blindness. This sport is one of the Paralympic games and is governed by the International Blind Sports Federation (IBSA). The game is played with modified FIFA (Fédération Internationale de Football Association) football 5-a-side rules. Football 5-a-side players are assigned to varying sports classes based on their level of visual impairment. Class B1 players are totally or almost totally blind, and Class B2 /3 have partial vision. For Class B1 games, teams consist of 4 field players with visual impairments, using eye shades to ensure fairness, and one goalkeeper who may be sighted. Teams may also use one guide, who is positioned behind the opponent's goal, to assist in directing players. The ball is equipped with a noise-making device inside to allow players to locate it by sound. During the game, players have to say clearly and audibly the word "voy" or "go", or any similar word, which prevents collisions between players, when seeking the ball and approaching the opponent. As little research has been performed on the athletes with disabilities relative to sports injuries (Ferrara and Peterson, 2000), especially in blind football players, the objective of this study is to find the features of sports injuries in blind football. **Methods** In this retrospective study, 15 male Japanese national team blind football players (all Class B1, mean (SD) age 29.8 (6.9) years) were interviewed and recorded, according to the FIFA standardized injury report form (Junge A, Dvorak J, et al., 2004). This study documented injury type and location caused by football during their respective careers as blind football players until June of 2010. An injury is defined as an absence from training or game for at least a week followed by diagnosis of anatomic tissue damage and medical treatment. **Results** The mean (SD) career as blind football player was 4.9 (2.3) years. During their careers, there were 31 total injuries among 9 players. The body parts injured were head / face (39%), trunk (19%), upper extremity (13%) and lower extremity (29%). The majority of injuries were diagnosed as fracture (32%), sprain (22%) and laceration / abrasion (13%). **Discussion** According to many studies of football-related sports injuries, the major locations of injury are lower extremities, especially in thigh, ankle, knee and lower leg (Junge A, Dvorak J, et al., 2004). In this study, head / face represented the major locations of injury in blind football players. Collisions between players predominantly caused head / face injuries. As players are completely unable to see during the game, they have to say clearly and audibly words like "voy" while approaching the opponent with a ball. Collisions seemed to happen, even between teammates, when they could not say the words instantly or properly. **References** Ferrara MS, Peterson CL (2000). Sports Med, 30, 137-143. ## RISK OF ACL INJURY IN SIDE CUTTING IN FOOTBALL: HALF-TIME RECOVERY IS MOSTLY INCOMPLETE AND DEPENDENT ON THE INDIVIDUAL

VANRENTERGHEM, J., MARKENDALE, E., ROBINSON, M.

LIVERPOOL JOHN MOORES UNIVERSITY

**Introduction** Non-contact ligament or muscle injuries at the knee remain a significant problem in sports involving manoeuvres which consist of rapid decelerations and changes in direction. In football most injuries occur in the last 15 min of each playing half, and more in the second half (Hawkins et al, 2001). The purpose of this study was to examine which exact changes occur in joint kinetics, kinematics and neuromuscular control of the stance limb during side cutting manoeuvres following 45 min football specific fatigue, and whether these changes returned to pre-fatigue level after half time rest. **Methods** Following ethical approval, 8 male recreational players in dynamic team sports volunteered to take part in the study (mean age  $21.1 \pm 2.0$  yr, height  $184.0 \pm 3.2$  cm, mass  $82.1 \pm 12.7$  kg). Each subject completed five side cutting manoeuvres pre-fatigue, immediately post-fatigue and 15 min post-fatigue. Approach speed was standardized at  $4.5 \text{ m.s}^{-1}$  and cutting angle at  $45^\circ$  from a straight run. A 45 min version of the SAFT90 football specific fatiguing protocol was used to elicit fatigue (Small et al., 2010). IR cameras (Qualysis, Sweden) were used to collect motion data at 250 Hz in synchrony with ground reaction force (Kistler, Switzerland) and wireless EMG (Noraxon, USA) at 1500 Hz. Joint kinematics and kinetics were computed for the stance limb based on a lower limb and trunk segmental model with functional hip and knee joints (Vanrenterghem et al., 2010). Muscle activity of rectus femoris, biceps femoris, gastrocnemius lateralis and soleus lateralis of the stance limb were measured. Results ANOVA tests showed increased ACL loading risk with fatigue due to  $5.2$  degrees reduced average knee flexion angle ( $F_{1,15}$ ,  $8.06 = 5.62$ ,  $P = 0.04$ ), a  $33.2 \text{ Nm}$  reduced maximum knee external rotation (internal muscle) moment ( $F_{1,17}$ ,  $8.20 = 8.77$ ,  $P = 0.02$ ), and reduced average biceps femoris activity ( $F_{2,14} = 17.97$ ,  $P = 0.000$ ). Post-hoc testing indicated that all of these variables were still reduced following the 15 min rest period, although the average knee flexion angle had partially returned to its pre-fatigued level. **Discussion** The fact that fatigue resulted in reduced knee flexion, decreased external rotation muscle moment, but similar knee internal rotation, suggests that after fatigue the ACL is at greater risk of injury, which remains after half time. While some participants did partially recover their joint kinetics and kinematics, others did not. Importantly, there was never neuromuscular recovery. **References** Small et al. ## COORDINATION VARIABILITY AND ACUTE INJURIES: A CASE STUDY

TREZISE, J.1,2, BUSSEY, M.1, BARTLETT, R.1

UNIVERSITY OF OTAGO1; EDITH COWAN UNIVERSITY2

**Introduction** Dynamical systems theorists deem that a functional role of coordination variability (CV) in human movement is its potential to decrease the risk of injury. While this relationship is still uncertain, changing the frequency, magnitude, or site of application of an applied force that is undergoing repetitive loading has possible benefits in the prevention and treatment of overuse injuries. While runners experience chronic, repetitive injuries due to the body suffering exposure to a recurring force, most hamstring injuries that befall sprinters are acute and caused by a traumatic event. With the different etiology involved, an acute injury may have a different relationship with CV. **Methods** A 27yr old male sprinter participating in an investigation to assess CV under fatiguing conditions over multiple 80m sprinting trials, pulled up with a grade one hamstring strain. The sprinter had performed six 80m repetitions at maximal speed on a 400m athletic track. Kinematic data of the last 40m of the 80m distance were collected by five digital video cameras (frame rate 50Hz). Timing gates situated at 10m intervals recorded sprinting speed throughout each trial to ensure any coordination changes were due to fatigue and not a change in speed. Skin markers were attached to the athletes' greater trochanter, lateral epicondyle, and lateral malleolus. Angle-angle plots, phase planes and continuous relative phase (CRP) illustrated the coordination dynamics between the knee and hip joints, and mean ensemble CRP values were used to compare differences in coordination on a trial-by-trial and stride-by-stride basis. Variability was determined by standard deviation (SD) between the trials while significance was determined as changes greater than  $\pm 2$  SD. **Results** Trial-by-trial comparisons of knee phase plane data show a significant increase in CV by trial six, particularly during the mid- and late-swing phases of the stride. Stride-by-stride, the injured sprinter showed similar patterns in CV to other sprinters, with lower limb CV decreasing from 40-50m to 70-80m. **Discussion** While there are many potential causes of hamstring injuries, most occur during the late-swing phase when the hamstrings are activated eccentrically to decelerate the knee extension before switching to extend the hip joint concentrically. The observed increase in CV at the knee across the trials may have been an adaptation to avoid further injury by finding new ways to coordinate the muscle fibres, particularly during the mid- to late-swing phase of the stride. While the exact reason why knee joint CV increased in this athlete is not known, it seems possible that while a decrease in CV is linked to chronic injuries in runners, perhaps a large increase in CV is related to those injuries which are acute.

## THE INFLUENCES OF THE TWELVE-WEEK FALL PREVENTION EXERCISE ON THE BALANCE ABILITY OF THE ELDERLY IN COMMUNITIES

HSU, T.Y.1, TSAI, Y.C.1, LUO, C.C.1, KUO, W.C.1, LIN, F.L.2, CHANG, C.L.2

1:NATIONAL TAICHUNG UNIVERSITY OF EDUCATION (TAIWAN), 2:GENERAL EDUCATION CENTER, HSIUPING INSTITUTE OF TECHNOLOGY (TAIWAN)

**Introduction** Aging is complex and inevitable natural phenomenon. Speaking of the human body structure, as years go by, body's each function and organization will degenerate gradually and the balance ability is the most obvious one. The balance ability refers to the ability that the body center of gravity to maintain stably on the base of support, and it is also the most essential role for human body to maintain and operate each movement. Since the balance ability drops, fall will occur and tremendous medical fees will come along as well. Fall prevention exercise is one of the newly-developed exercises during recent years. Designers expect that the fall prevention exercise can enhance flexibility and strength, postpone degeneration of strength, promote the balance control ability of human postures, and then prevent the elderly from tumbling. **Methods** The subjects were 54 senior citizens in communities from Dajia District, Taiping District, and Shalu District in Taichung City, Taiwan, and they were evenly divided into the common exercise group, fall prevention exercise group, and control group. Kistler force platform (100Hz) and 3-meter walking were employed to measure the parameters of the static balance, dynamic balance, and lower-extremity strength. Then the fall prevention exercise group took the 12-week fall prevention exercise training and it took the posttest after the training was finished. The data were analyzed by the paired sample t test and one-way ANOVA to compare the results of the pretest and posttest and difference among groups and then examine whether the fall prevention

exercise training promotes the balance ability. Results The result indicated that the fall prevention exercise enhanced the performance of the time of right or left foot standing, average moving speed, 3-meter walking time, and the rate of develop force of lower-extremity strength ( $p < .05$ ). Discussion The fall prevention exercise is adequate for the elderly to take and it is also a preventive exercise for everyone to popularize. References Cao, Z. ## THE IMPACT OF LEISURE TIME PHYSICAL ACTIVITY ON MUSCULOSKELETAL COMPLAINTS IN YOUNG ADULTS THE NORWEGIAN NORD-TRØNDELAGE HEALTH STUDY

KIRKVOLD, H., GUNDERSEN, K.T., MEIRIK, R.

NORD-TRØNDELAGE UNIVERSITY COLLEGE OF NORD-TRØNDELAGE, TRØNDELAGE RESEARCH AND DEVELOPMENT INSTITUTE, CENTRAL NORWAY REGIONAL HEALTH AUTHORITIES

Abstract A major part of the population in Norway is affected by musculoskeletal complaints (MSC) and low back complaints (LBC). Due to occupational disability and days of sick leave, this entails great negative economical consequences (Ihlebaek og Lærum 2010; Andersen et al. 2009). Findings indicate that physical activity may have positive impact on MSC as well as on LBC (Hildebrandt, Bongers, Dul, et al. 2000; Heneweere H, Vanhees L, Picavet HS 2009; Schneider S, Zoller S 2009). However, little research has been conducted to investigate whether leisure time physical activity ("friluftsliv") has general impact on MSC or more specifically on LBC. The definition of Vet et al. (2002) is used in this study on the concepts MCS and LBC including pains, problems or dislike in the neck, the upper part of the back and the shoulders and the lower part of the back. The model and the theory of Horgen (2001) and Odden (2008) identifies several hallmarks of "friluftsliv" like physical activity, leisure time, nature, the open air, culture, experience and change of environment. The aim of the study was to investigate the associations between gender, age, "friluftsliv" and MSC and LBC. Data from the Norwegian Nord -Trøndelag Health Study (HUNT 3-2006-2008) were used in the study. Young adults (20-29 years, N=4242) participated in the study. Associations between gender, age, "friluftsliv" and MSC and LBC were assessed by analysis of variance (ANCOVA) and logistic regression. Gender and "friluftsliv" associated significantly with MSC and LBC. Moderate participation in "friluftsliv" had positive impact on MSC and LBC with reduced complaints. Male subjects reported less MSC and less LBC than female subjects. References Andersen, I., Frydenberg, H., Mæland, J. G. ### PP-PM77 Anthropometry 2

## RELATIONSHIP OF ANTHROPOMETRIC WITH PHYSICAL AND MOTOR FITNESS FEATURES IN IRANIAN ELITE SOCCER PLAYERS

TARVERDIZADEH, B.

ISLAMIC AZAD UNIVERSITY, TEHRAN BRANCH

The purpose of this research was to determine the relationships between selected anthropometric with physical and motor fitness measures in elite Iranian soccer players. Among the players of national team, 60 elite men were selected voluntary as an overall sample. The anthropometric measures included, body mass index (BMI), fat %, weight, lean body mass, height and also chest, leg and thigh circumferences and body composition from total of 60 elite players. Also measurements (sectioned as: skinfolds, girths, lengths, and breadths) were made for each player. The procedure involved three measures at each site to calculate a mean value and used to relate with fitness variables. The physical and motor fitness tests used were: ergo jump, vertical jump, agility, flexibility, speed and reaction time. Mean calculated scores for all players were obtained. Regression analyses indicated significant correlation between certain variables of Fitness tests and variables of anthropometric estimation statistics. Knowing these relationships provides us with valuable predictive information about player's Capabilities in sport. Results showed between have less body mass index (BMI), less fat%, greater lean body mass, great leg and thigh circumferences were significantly related to better speed, agility, ergo jump and vertical jump. Also observed greater height with vertical jump ( $p < 0.05$ ) and relationships between agility and flexibility to less fat observed too. Regression analysis for all variables demonstrated a significant relationship between some parameters. These findings suggest that we can predict some variables of anthropometric or physical and motor fitness by other parameters.

## A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE EFFECT OF AEROBIC AND RESISTANCE EXERCISE TRAINING ON VISCERAL FAT

JOHNSON, N.1, ISMAIL, I.1, BAKER, M.2

1: UNIVERSITY OF SYDNEY (SYDNEY, AUSTRALIA), 2: EDITH COWAN UNIVERSITY (JOONDALUP, AUSTRALIA)

**Introduction** The increased risk of cardiovascular and metabolic morbidity and mortality as result of obesity has been well described. However, it is increasingly recognized that the location of excess adiposity, particularly increased deposition of visceral adipose tissue (VAT), is of greater importance in determining the adverse health effects of overweight and obesity. A systematic review of the available randomized control trials to 2006 suggested that interventions involving increased aerobic exercise (AEx) can benefit abdominal fat (Kay and Fatarone Singh, 2006). Although there are currently no guidelines for progressive resistance exercise training (PRT) in the management of obesity, there is evidence that PRT may result in VAT reduction (Kay and Fatarone Singh, 2006). **Methods** A systematic review and meta-analysis was performed to assess the efficacy of exercise interventions on VAT content/volume in overweight and obese adults. Relevant databases were searched to November 2010. Included studies were randomised controlled designs in which AEx or PRT in isolation or combination was employed for 4 weeks or more in adult humans. Studies were selected if computed tomography or magnetic resonance imaging was used for quantification of VAT fat area/volume pre- and post-intervention. Results Of the 12,196 studies from the initial search, 35 were included. After removal of outliers there was a significant pooled effect size (ES) for the comparison between AEx therapy and control (-0.29, 95% CI: -0.42 to -0.17;  $P < 0.01$ ), but not for comparison between PRT therapy and control (-0.03, 95% CI: -0.21 to 0.14;  $P = 0.71$ ). Of the available nine studies which have directly compared AEx with PRT, the pooled ES did not reach statistical significance (ES = 0.19, 95% CI: -0.04 to 0.41;  $P = 0.105$  favouring AEx). The pooled ES did not reach statistical significance for interventions that combined AEx and PRT therapy versus control (-0.15, 95% CI: -0.35 to 0.04;  $P = 0.12$ ), for which only seven studies were available. **Discussion** We aimed to evaluate the independent and synergistic effects of aerobic exercise and progressive resistance therapies and to directly compare the efficacy of aerobic exercise and resistance training interventions for beneficial VAT modulation. These data suggest that aerobic exercise may be a superior training modality for achieving reductions in VAT but further investigation is needed regarding the efficacy and feasibility of multi-modal training as a means of reducing VAT. **References** Kay S and Fatarone Singh, M. (2006). *Ob Rev*, 7, 183-200.

## EFFECT OF A 6-MONTH DEPLOYMENT TO AFGHANISTAN ON PHYSICAL FITNESS AND BODY COMPOSITION OF CROATIAN ARMED FORCES

BOK, D., JUKIC, I., DIZDAR, D., VUCETIC, V.

FACULTY OF KINESIOLOGY UNIVERSITY OF ZAGREB

**INTRODUCTION** Engagement in military operations is considered an extremely physically demanding job. To meet these hard physical requirements soldiers are engaged in everyday physical training. However, during deployments soldiers are often deprived of such training routines and can experience significant decrements in physical fitness (PF). The main goal of the study was examining the change in PF and body composition (BC) after a 6-month military deployment to Afghanistan. **METHODS** The research was conducted on a sample of 59 professional soldiers of the Croatian Armed Forces. PF and BC were assessed prior and post deployment with the battery of 12 motor and functional tests and 2 morphological measures respectively. Pre-deployment to post-deployment changes in PF and BC were analysed using ANOVA. **RESULTS** Result showed significant decrement in percentage of body fat (14.66;  $p = 0.00$ ), while body weight (BW) did not change at all. Decrements in PF were registered in most variables (coordination, sprinting power, jumping power) with significant changes in agility, abdominal and upper body repetitive strength, aerobic and anaerobic endurance. The only improvement in PF was registered in flexibility, but this change was not statistically significant. **DISCUSSION** After a 6-month deployment to Afghanistan soldiers reduced their body fat without changing their BW and also experienced overall decrement in PF. Body fat loss is probably related to the changes in dietary habits and food selection while PF decrements are mostly related to the lower physical requirements of the deployment and the lack of scheduled exercise. In order to maintain optimal PF level during deployments, soldiers should be encouraged to continue with their exercise programmes as conducted prior to deployment. **REFERENCES** Sharp, M.A. (2008). *Med Sci Sport Exer*, 40(9), 1687-1692. ## ANTHROPOMETRIC AND BODY COMPOSITION PROFILES OF ELITE IRANIAN MALE CANOE POLO PLAYERS

SHEIKHLOUVAND, M.1, AGHA-ALINEJAD, H.1,2, BAYATI, M.2, KHALILI, E.3, ISANEJAD, A.2, FARZAD, B.4

1: ISLAMIC AZAD UNIVERSITY, CENTRAL TEHRAN BRANCH (TEHRAN, IRAN), 2: NATIONAL CANOEING, ROWING & SAILING ACADEMY (TEHRAN, IRAN), 3: ISLAMIC AZAD UNIVERSITY, KARAJ BRANCH, 4: TARBIAI MODARES UNIVERSITY

This study is supported by National Canoeing, Rowing & Sailing Academy (Tehran, Iran) **Introduction** Canoe Polo is a strength-power type of sport and competition performance depends on factors such as strength and anaerobic power, physical power, canoe polo technique and tactics. A vast amount of research has been conducted on water sports similar to dragon boating, and it has been found that there are major differences in the anthropometric and body composition characteristics between rowers, kayak paddlers and canoeists. However, there is not information available on the anthropometric and body composition characteristics of canoe polo players. **Methods** The subjects were fifteen elite male canoe polo players from the Iranian National team who competed at the 2011 Asian canoe polo championships in Tehran, Iran. Anthropometric and body composition measures were included weight, height, arm span, sitting height, Body Mass Index (BMI), Present Body Fat (PBF), Basal Metabolic Rate (BMR). Anthropometric measurements: A total of anthropometric variables were directly and indirectly measured according to the methods of standard International Society for the Advancement of Kinanthropometry (ISAK). For all the anthropometric measurements, standards of ISAK procedures were followed (Agha-Alinejad et al., 2010). Body Composition measurements: Their body composition was analyzed using Inbody 520 (Korea). Statistical analysis: Descriptive statistics were calculated for all variables. All statistical analyses were conducted using SPSSv16.0. **Results** Anthropometric variables (Mean  $\pm$  SD: age  $24.6 \pm 3.1$  years, height  $179.4 \pm 5.1$  cm, arm span  $185.7 \pm 5.5$  cm, sitting height  $94.3 \pm 4.0$  cm) and body composition variables (Mean  $\pm$  SD: weight  $82.9 \pm 7.6$  years, BMI  $25.7 \pm 2.0$  kg/m<sup>2</sup>, PBF  $14.4 \pm 2.8$  %, BMR  $1901.7 \pm 110.2$  Kcal in Day). **Discussion** This is the first study to present a detailed analysis of the anthropometric and body composition characteristics of canoe polo players. Descriptive anthropometric characteristics offer a unique wealth of information that can be used to analysis the size, proportionality, and body composition of athletes. This athlete profiling can be used by health and sports science practitioners in canoe polo for the design of exercise and nutrition interventions to improve health and performance (Ackland et al., 2009), for talent detection purposes and in the analysis and modelling of physical aptitude characteristics specific to the sport (Holway and Garavaglia., 2009) **References** Ackland TR, Elliott BC,

### SOMATOTYPE AND SIZE OF ELITE IRANIAN MALE SWEEP ROWERS

BAYATI, M.1, AGHA-ALINEJAD, H.1, DONYAMALI, A.2, FARZAD, B.3, YOUSEFI, V.1, ISANEJAD, A.1

1: NATIONAL CANOEING, ROWING & SAILING ACADEMY (TEHRAN, IRAN), 2: CANOEING, ROWING & SAILING FEDERATION OF I.R.IRAN (TEHRAN, IRAN), 3: TARBIAT MODARES UNIVERSITY (TEHRAN, IRAN),

**Introduction** Identification of the unique aspects of physique that may contribute to success in sport has long interested sports scientists and coaches. Within a sport such as rowing, tallness is an obvious competitive advantage. Rowing is a weight-supported sport and anthropometric data of elite adult rowers emphasize the importance of the body mass and size. Successful open class rowers are as lean, but much heavier and taller, with long arms and a tall sitting height compared with athletes in other endurance sport disciplines. Long arms are helpful in obtaining an adequate stroke length. Because rowing is a strength endurance sport, in which body mass and body size are performance-related factors. Sweep rowers in open class are consistently taller and heavier than scullers, amounting to 2 cm and 4 kg for men, and 3 cm and 3 kg for women. The reason why sweep rowers are heavier, taller and more muscular than scullers may be a result of the dynamics of boat movement (Secher and Volianitis, 2007). **Methods** The subjects were thirteen (4 male lightweight and 9 male heavyweight) elite male Sweep rowers from the Iranian National team (Mean  $\pm$  SD lightweight: age  $19.7 \pm 0.5$  years, height  $187.7 \pm 4.1$  cm, body mass  $71.6 \pm 1.3$  kg and Mean  $\pm$  SD heavyweight : age  $22.0 \pm 1.5$  years, height  $194.5 \pm 4.0$  cm, body mass  $90.3 \pm 6.4$  kg ) who competed at the 2010 Asian Games in Guangzhou, China. Anthropometric measurements: A total of anthropometric variables were directly and indirectly measured according to the methods of standard International Society for the Advancement of Kinanthropometry (ISAK). For all the anthropometric measurements, standards of ISAK procedures were followed. Descriptions of measurement techniques are given later (Agha-Alinejad et al, 2010). Somatotype was calculated using the Heath-Carter protocol (Eston and Reilly, 2009). **Results** The mean somatotype for the male lightweight rowers (2.3-2.3-3.9) demonstrates that these athletes were predominantly ectomorphic. The mean somatotype for the male heavyweight rowers (2.8-5.0-3.3) demonstrates that these athletes were predominantly mesomorphic. **Discussion** Boats with sweep oars on average involve more athletes and a coxswain in the coxed pair, four and eight. The weight of the coxswain imposes a greater deceleration of the boat at the catch of the stroke, where the blade enters the water and force is applied to the oar, because of the change of the direction of the bodies in the boat and a high force is required to accelerate the boat. Thus, tall, muscular and heavy rowers are favored (Secher and Volianitis, 2007). **References** Agha-Alinejad H, Donyamali A, Bayati M, Mirakhori Z, Yousefi V, Farzad B (2010). 11th International Sport Sciences Congress, 1009-1011. ### BODY COMPOSITION AND PHYSICAL PERFORMANCE IN ELITE SPANISH BASKETBALL PLAYERS

MARTINEZ MUNOZ, P.

UNIVERSITY OF LAS PALMAS DE GRAN CANARIA

Team sport performance is determined by a diverse range of qualities including body size, fitness, sport-specific skills, team tactics, and psychological attributes. The game of basketball requires big body size and physical. A player's size has a large influence on the position in the team, while the high-intensity, intermittent nature of the physical demands requires players to have a high level of fitness (Drinkwater et al, 2008). **PURPOSE:** To determine the anthropometric profile, body composition and explosive strength development of elite basketball players. **METHODS:** Ten male basketball players (age =  $24.1 \pm 2$  yr, height =  $195.9 \pm 8.8$  cm, body mass =  $95.7 \pm 10.9$  kg, body fat =  $10.9 \pm 1.1\%$ ) who played in the Fourth League of Spain (EBA), participated in this study. Body composition was calculated by measuring weight, height, skinfolds, limb circumference, and joint diameter. VO<sub>2</sub>max and jump tests were evaluated at the beginning of the season. The height jumped (VJH), the mechanical positive impulse (MPI), the peak power (PP), the mean power (MP), and the maximal force (MF) achieved during countermovement vertical (CMJ) jump, squat jump (SJ) and Abalakov (ABK) test where were assessed with a force plate. **RESULTS:** Mean and standard deviation values were: [VO<sub>2</sub>max =  $55.3 \pm 6.2$ ]; [VJH=  $32.1 \pm 2.0$ ,  $38.1 \pm 3.0$ ,  $45.6 \pm 4.6$  cm]; [MPI=  $24.4 \pm 3.9$ ,  $26.3 \pm 3.1$ ,  $28.9 \pm 3.6$  Kp.s]; [MP=  $19.7 \pm 2.8$ ,  $29.7 \pm 2.2$ ,  $31.5 \pm 4.5$  w/kg]; [PP=  $46.7 \pm 5.6$ ,  $52.2 \pm 4.1$ ,  $63.9 \pm 5.8$  w/kg]; [MF=  $118.5 \pm 25.7$ ,  $138.4 \pm 23.2$ ,  $161.2 \pm 40.5$  kp], SJ, CMJ and ABK respectively. **CONCLUSION:** These basketball players have 10-15% greater VO<sub>2</sub>max capacity than the non-active subjects of comparable age from the Spanish population. Their jumping capacities are also slightly higher than observed in sedentary subjects from our population and lower than in volleyball players.

### 'THE ANTHROPOMETRIC, PHYSIOLOGICAL, PHYSICAL AND MOTOR FITNESS FEATURES PROFILES IN THE IRANIAN SOCCER ELITE PLAYERS'

TARVERDIZADEH, B., AZARBAYJANI, M.A.

ISLAMIC AZAD UNIVERSITY, TEHRAN BRANCH

The aim of the current investigation was to determine the anthropometric, physical and motor fitness features profiles in the IRANIAN soccer elite players. From the national team's players, 30 elite male were used as an overall sample and as voluntary. The players were analyzed according to the specific positions in the field. The anthropometric measures included body composition from total of 30 elite players. Also measurements (sectioned as: skinfolds, girths, lengths, and breadths) were made for each player. The procedure involved three measures at each site to calculate a mean value and compare with other positions. This case performed in all factors and positions. The physiological tests used were: VO<sub>2</sub>max, ventilation, maximum of heart rate. The physical and motor fitness tests used were: ergo jump vertical jump, agility, flexibility run and reaction time. . Mean calculated scores for playing position were obtained. A multivariate analysis of variance revealed differences between positions. The result showed, strikers players performed, higher speed. Reaction, agility, and flexibility, but lower vertical jump and height. Midfielder's players showed lower fat percent and higher Vo<sub>2</sub>max in compare with other positions. Also defenders players were higher weight, lean body weight, height and vertical jump from other positions. A range of relevant anthropometric , physical fitness and physiological factors can be considered which are subject to strong genetic influences or are largely environmentally determined and susceptible to training effects. Consequently, fitness profiling can generate a useful database against which talented groups may be compared. No single method allows for a representative assessment of a player's

physical capabilities for soccer. We conclude that anthropometric physical and physiological criteria do have a role as part of a holistic monitoring of talented elite players.

### SOMATOTYPE COMPONENTS OF JUNIOR ELITE HANDBALL PLAYERS

NOUTSOS, K., BOTONIS, P.G., BAYIOS, I.

UNIVERSITY OF ATHENS

**Introduction** Kinanthropometric studies have shown that high performance requires specific morphological characteristics. Body composition (body fat, body mass, muscle mass) and physique (somatotype) can significantly influence athletic performance (Carter & Heath, 1990). The aim of this study was to detect possible differences in somatotype components of junior elite handball players in three different age groups. **Methods** The study sample were members of the Greek national handball teams divided into three age groups: under 16 years old (U-16: n=20, age 15.9±0.4 years, height 182.4±6.6 cm, body mass 78.2±8.1 kg), under 18 years old (U-18: n=19, age 17.4±0.5 years, height 184.07±5.8 cm, body mass 84.2±9.8 kg) and under 20 years old (U-20: n=21, age 19.3±0.6 years, height 184.7±5.2 cm, body mass 85.4±7.6 kg). All anthropometric measurements were taken according to Heyward & Stolarczyk (1996) guidelines. Somatotype was determined using the method of Carter & Heath (1990). One way ANOVA was conducted in order to determine significant differences among the three subgroups. Statistical significance was set at p<0.05 level. **Results** No significant differences were found in endomorphy, mesomorphy and ectomorphy among the three age groups of players. U-16 somatotype is characterized as central (2.8-3.1-2.7), while U-18 and U-20 had almost the same somatotype characterized as mesomorph-endomorph (3.0-3.3-2.2 and 3.0-3.4-2.1, respectively). In all three groups mesomorphic component was the highest, while ectomorphic the lowest. **Discussion** The main finding of the present study was that the somatotype of elite junior handball players is characterized primarily by mesomorphic and secondly by endomorphic component. The presence of higher muscle mass reflected in the mesomorphic component constitutes a significant advantage for athletes in order to confront the intense body contacts during a handball game. In the last decade, there is only one study (Sibila & Pori, 2009) dealing with somatotype components of top-level male handball players. In the aforementioned study, athletes exhibited markedly higher mesomorphy values [3.0-4.8-2.2], than our study and were characterized as endomorphic-mesomorph. **References** Carter JEL, Heath HB. (1990). Somatotyping – development and application. Cambridge University Press. Sibila M, Pori P. (2009). Coll. Antropol 33,4: 1079-86. Heyward V, Stolarczyk L. (1996). ### THE EVOLUTION OF PHYSIQUE, AGE AND SPORTING EXPERIENCE IN MALE OLYMPIC HANDBALL

SKARBALIUS, A.

LITHUANIAN ACADEMY OF PHYSICAL EDUCATION

**Introduction** Physique factors are important for success in a particular sport (Norton, Olds, 2001). The aim of the research was to carry out the tendencies of height, body mass, age, sporting experience of male olympic handball players through 4 decades: from Munich (1972) Olympic Games (MOG) to the Beijing (2008) Olympic Games (BOG). **Methods** The indices of height, body mass, age, and the international matches played by handball players (N=1869) of national teams taking part in 10th Olympics were taken from the official statistics documents of the International Handball Federation. All values were expressed as means ± SD. The data were analysed by means of the variance (ANOVA) and linear regression methods. Pearson's correlation method was used for assessing the mentioned indices influence to win. The value of P < 0.05 was accepted as significant. **Results** During 36 years (from MOG to BOG) all indices increased statistically significant (P < 0.001). The height of handball players increased by 6.3 cm (184.8 x ± 5.0 and 191.1 ± 6.51 respectively) (y = 0.7867 x + 184.54; R<sup>2</sup> = 0.8382), body mass – by 10.1 kg (82.3 ± 5.58 and 92.4 ± 8.62 respectively) (y = 1.4571 x + 81.618; R<sup>2</sup> = 0.9579), age – by 2.6 years (25.9 ± 3.33 and 28.5 ± 4.12 respectively) (y = 0.405 x + 24.808; R<sup>2</sup> = 0.8499), international matches played increased in double – by 48 matches (45.5 ± 31.2 and 93.4 ± 9.7 respectively) (y = 11.857 x + 33.667; R<sup>2</sup> = 0.706). **Discussion** In all OG (except Moscow 1980) champions were higher, greater body mass, older, more experienced than handball players in average or winners of medals (Skarbalis, 2002, 2010). Despite findings of importance of body size in elite performance (Ackland, 2005; Gabbet, 2006) current study did not show uniformity of prevalence of height, body mass, or experience to win a match in male olympic handball. Correlation between winnings points and indices varied from OG to OG: height (0.238–0.791), body mass (0.271–0.657), age (0.133–0.798), international matches played (0.243–0.666). In conclusion we suggest that playing pattern in elite male olympic handball may have more influence to win than body size (Skarbalis, 2010). **References** Ackland T. (2005). ### COMPARISON OF GENDER AND SPORT BRANCHES BETWEEN ANAEROBIC POWER, STRENGTH, SOME ANTHROPOMETRIC CHARACTERISTICS, SPEED AND REACTION TIME

AKAN, I.I., KAYA, F.I., BAKIR, Z.I

UNIVERSITY OF MARMARA SCHOOL OF PHYSICAL EDUCATION AND SPORTS

**Introduction** Gender and Sport branches (in team handball and soccer) are considered as important aspects of the game and contribute to the high performance of the team. Therefore, the aim of this study was to compare gender and sport branch between anaerobic power, some anthropometric characteristics, speed, strength and reaction time? **Methods** The total sample consisted of 40, male (n=20) and female (n=20). Team handball (age=21.30±2.8) and soccer (age=22.95±2.8) players who has been student at Marmara University of School of Physical Education and Sports. Anaerobic power was calculated by Lewis Formula (Fox, 1984). Vertical jump and Reaction time were measured by MPS-5001F Kompe System. Descriptive data was computed for all variables. Two way ANOVA was used. Statistical significance was set at p<0.05 **Results** Gender effect was stated at 30 m. Speed, anaerobic power, arm span, hand length, hand grip strength and standing long jump, except reaction time. Sport branch effect was stated at hand grip strength. Both gender and sport branch effect was stated at vertical jumping, reaction time and leg strength (p<0.05) **Discussion** Gender's effect: 30 m. Speed, anaerobic power, arm span, hand length, hand grip strength and standing long jump of male better than female (p<0.05). This findings was supported another research about 30m speed and standing long jump (Zapartidis et al., 2009) Sport branch's effect: Hand grip strength of handball players better than soccer players (p<0.05). Hand grip strength that is important in handball, from the moment pass is received

till the throw is affected from the arm segment isometric muscle force (Eler, Sevim, 2002). Both gender and sport branch's effect : Leg strenght and reaction time of male and female soccer players better than handball players ( $p < 0.05$ ). ### IS ANTHROPOMETRIC PROFILE OF ELITE MALE ICE CLIMBERS SAME AS PROFILE OF THE SPORT CLIMBERS?

VUJIC, S.1, MIRKOV, D.2, DIKIC, N.1, KUPPER, T.3, TOTIC, S.4, DJOKOVIC, A.4, RADIVOJEVIC, N.1, ANDJELKOVIC, M.1, OBLAKOVIC, B.J.1, BARALIC, I.5

1:SMAS,BELGRADE;2:FACULTY OF SPORT AND PHYSICAL EDUCATION,BELGRADE;3:AACHEN TECHNICAL UNIVERSITY,GERMANY;4:FACULTY OF ORGANIZATIONAL SCIENCES, BELGRADE;5:FACULTY OF PHARMACY,BELGRADE

Introduction: Ice climbers (IC) commonly used knowledge regarding body composition, strength, endurance and flexibility on the basis of previous studies of sport climbers (SC). The aim of this study was to compare anthropometric profiles of elite IC and SC. Methods: The 23 male participants (age  $26.7 \pm 5.9$ ) of the Ice climbing World Cup were measured day before competition. Control group was made of 23 SC (age  $27.9 \pm 3.9$ ) who reported on site climbing grade over VII+/6c (UIAA/French) (Watts PB., 2004). The variables measured included age, height, weight, body mass index, % body fat by bioimpedance, % segmental body fat (trunk, left and right arms, -legs), fat mass, fat-free mass (FFM), total body water (TBW), basal metabolic rate (BMR), leg length, arm span, ratio of arm span to height (Ape index), right and left handgrip strength, handgrip strength to body mass ratio (SMR), pincer strength (dominant hand, i.e. thumb and forefinger), handgrip endurance (dominant hand), endurance of shoulder's muscles, foot raise, hip flexion, hip abduction and climbing ability through standing position or the most difficult on site lead climbing (Grant S., 1996; Giles LV., 2006). Results: We have found significant differences ( $p < 0.05$ ) between IC and SC for body fat % (IC  $9.4 \pm 2.3$ ; SC  $6.5 \pm 2.2$  %), fat mass (IC  $6.6 \pm 2.1$ ; SC  $4.7 \pm 1.9$  kg) and trunk fat % (IC  $9.5 \pm 3.9$ ; SC  $5.5 \pm 3.0$  %). IC have weaker ( $p < 0.05$ ) hand grip (left hand: IC  $442 \pm 96$ ; SC  $575 \pm 83$  N / right hand: IC  $495 \pm 95$ ; SC  $589 \pm 78$  N), SMR (IC  $7.0 \pm 1.1$ ; SC  $8.5 \pm 1.0$  N/kg) and foot rise (IC  $68 \pm 6$ ; SC  $76 \pm 7$  cm). No difference has been found for pincer strength, grip endurance, endurance of shoulder's muscles, hip flexion and abduction. Discussion: This results indicate that Ice climbers have lower body fat, probably as a reaction on cold environment. On other side all Sport Climbing training protocols for development of strength, endurance and flexibility can be used by Ice climbers because of their elementary influence on climbing sport performance (Grant S., 1996; Giles LV., 2006). ### PP-PM78 Exercise in Disease and Ageing

#### NO ADVERSE EFFECTS OF STATINS ON MUSCLE FUNCTION AND HEALTH-RELATED PARAMETERS IN THE ELDERLY: AN EXERCISE STUDY

PANAYIOTOU, G., PASCHALIS, V., NIKOLAIDIS, M.G., THEODOROU, A.A., FOTOPOULOU, N., FATOUROS, I.G., KOUTEDAKIS, Y., JAMURTAS, A.Z.

EUROPEAN UNIVERSITY OF CYPRUS

Introduction Statins are currently the most effective drugs for the therapy of hypercholesterolemia. However, the side effects of statins (myalgia, fatigue and muscle pain) may negatively impact the quality of life especially in elderly, leading to limited physical activity. Therefore, the aim of the present study was to investigate the effects of a repeated bout of eccentric exercise on health related parameters and muscle performance on subjects undergoing statin therapy. Methods Twenty eight elderly men participated in the investigation and were assigned in a control ( $n = 14$ ) and a statin therapy group ( $n = 14$ ). All participants performed two isokinetic eccentric exercise bouts separated by three weeks. During both sessions, participants completed 5 sets of 8 eccentric maximal voluntary contractions. Muscle damage indices evaluated before, immediately after, as well as 48h and 120h post-exercise. Resting energy expenditure (REE), substrate metabolism (RQ), lipid profile (i.e. total cholesterol, high and low density lipoproteins, triacylglycerols) and insulin sensitivity (i.e. insulin, glucose and HOMA) were evaluated before exercise as well as 48h and 120h post-exercise. Results All muscle function indices were modified significantly after the first bout of eccentric exercise in both groups, but the alterations were smaller after the second bout of eccentric exercise. No differences in muscle function were observed between the two groups. Eccentric exercise increased REE, decreased RQ, improved lipid profile and increased insulin sensitivity 48h after both eccentric exercise bouts. However, these changes appeared to lesser extent after the second bout. No differences were observed in the responses in the health related parameters in the control and in statin therapy group. Discussion Eccentric exercise affected similarly skeletal muscle function, substrate metabolism, blood lipid profile and insulin sensitivity in the control and in statin treated individuals. These findings indicating that statin therapy individuals does not negatively affect skeletal muscle function, health related responses and adaptation to eccentric exercise.

#### EXERCISE TRAINING IMPROVES PHYSICAL FITNESS AND VASCULAR FUNCTION IN CHILDREN WITH TYPE 1 DIABETES

SEEGER, J.P.H., THIJSEN, D.H.J., NOORDAM, K., CRANEN, M.E.C., HOPMAN, M.T.E., NIJHUIS-VAN DER SANDEN, M.W.G.

RADBOD UNIVERSITY NIJMEGEN MEDICAL CENTRE

Children with diabetes mellitus type 1 (DM1) demonstrate endothelial dysfunction and mild artery wall thickening compared to their age-matched healthy peers. We examined the effect of 18-week exercise training on physical fitness, and vascular function and structure in children with DM1. We examined physical fitness, brachial artery endothelial function (flow-mediated dilation (FMD)) and common carotid artery diameter, wall thickness and wall-to-lumen ratio before and after 18-week exercise training in children with DM1 ( $n=7$ ). Physical fitness, measured as maximal oxygen consumption, improved after training ( $P=0.039$ ). Brachial artery FMD improved from  $7.5 \pm 4.2$  to  $12.4 \pm 5.2$  ( $P=0.038$ ). Carotid artery diameter, wall thickness and wall-to-lumen ratio did not change significantly ( $P=0.26$ ,  $0.53$  and  $0.27$ , respectively). We demonstrated that exercise training in children with DM1 effectively reverses endothelial dysfunction and improves physical fitness. These data emphasize the important role for physical activity in the management of DM1.

### LONG TERM RECREATIONAL PHYSICAL EXERCISE DECREASED ANGINA SUSCEPTIBILITY, REDUCED THE MYOCARDIAL INFARCT SIZE, IMPROVED THE HEART PERFUSION IN RATS

POSA, A.1, SZABO, R.1, SZABLICS, P.2, VARGA, C.1, MAGYARINE BERKO, A.1, ORBAN, K.2, LASZLO, F.1,2

UNIVERSITY OF SZEGED

**Introduction** Physical inactivity, i.e. sedentary life style increases circulatory disease risk. Carbon monoxide and nitric oxide produced by the heme oxygenase (HO) and by the constitutive nitric oxide synthase (cNOS) protect circulation. In contrast, the enhanced level of the matrix metalloproteinase (MMP) augments cardiovascular risks. We examined the actions of recreational physical exercise on the expression of these enzyme systems in conjunction with cardiovascular protection. **DESIGN:** Male Wistar rats were placed into cages installed with running wheels allowing them the self administration of physical exercise over 6 weeks. We studied 1./ the activity and expression of HO and NOS in the aorta and heart left ventricle (LV); 2./ the serum level of MMP-2; 3./ the angina susceptibility of the heart (assessed by lead II. surface ECG following adrenaline plus phentolamine challenge); 4./ the Infarct size by triphenyltetrazolium chloride staining was measured in hearts isolated from both groups and subjected to 30 min coronary occlusion followed by 120 min reperfusion; and 5./ the heart perfusion provoked by AVP according to Langendorff. **Results** We found that physical exercise 1./ increased LV and aortic HO activity (from  $0.83 \pm 0.21$  to  $5.35 \pm 0.36$  and from  $0.73 \pm 0.15$  to  $1.60 \pm 1.13$  nmol bilirubin/h/mg protein, respectively;  $n=12-15$ ;  $p<0.001$ ) and LV HO-1 isoenzyme expression (from  $106.3 \pm 3.132$  to  $164.0 \pm 16.479\%$ ;  $n=6-7$ ;  $p<0.05$ ) and increased LV and aortic cNOS activity (from  $16.32 \pm 3.71$  to  $59.11 \pm 7.94$  and from  $105.38 \pm 55.72$  to  $181.78 \pm 30.29$  pmol/min/mg protein, respectively;  $n=9-15$ ;  $p<0.001$ ) and LV endothelial NOS isoenzyme expression (from  $109.15 \pm 5.247$  to  $163.1 \pm 10.67\%$ ;  $n=3$ ;  $p<0.05$ ); and 2./ decreased serum and cardiac MMP-2 level (64 kDa; from  $1002.71 \pm 37.50$  to  $679.73 \pm 34.35$  intensity  $\times$  mm<sup>2</sup>;  $n=12-13$ ;  $p<0.001$ ); 3./ decreased heart ischaemia susceptibility (ST segment depression: from  $-0.14 \pm 0.018$  to  $-0.019 \pm 0.019$  mV;  $n=11$ ;  $p<0.001$ ); 4./ decreased the infarct size (from  $51.2 \pm 6.86$  to  $30.17 \pm 3.66\%$ ;  $n=5-6$ ;  $p<0.05$ ); and 5./ increased the isolated heart perfusion (from  $11.6 \pm 3.14$  to  $6.17 \pm 2.16\%$ ;  $n=8$ ;  $p<0.05$ ). **Discussion** Long term recreational physical exercise protects the heart against angina, decreased the infarct size and improved the isolated heart perfusion which might be associated with the up-regulation of the HO and NOS enzyme system, and the down-regulation of MMP-2 activation. Grant supports: SROP 4.2.1./B-09-1/KNOV-210-0005; SROP 4.2.2.-08/1-2008-0006; Bolyai Scholarship (Aniko Posa).

### SKELETAL MUSCLE FIBRE CONDUCTION VELOCITY AND EMG ACTIVITY, BEFORE AND AFTER REHABILITATION IN PATIENTS WITH CHRONIC CARDIAC DISEASE: A PILOT STUDY

ALBERTUS-KAJEE, Y.1, HUNTER, A.2, SCHWELLNUS, M.1, DERMAN, W.1

1) UNIVERSITY OF CAPE TOWN; 2) UNIVERSITY OF STIRLING, DEPARTMENT OF SPORTS STUDIES, SCOTLAND

**Introduction** Patients with chronic cardiac disease are shown to have secondary structural and functional changes that occur in the skeletal muscle which can result in decreased functional capacity and exercise intolerance. Previous studies have shown that supervised exercise rehabilitation programs result in improvements in functional capacity (1; 2) but the exact effect of exercise training on skeletal muscle activity in these patients is unknown. Therefore the aim of the study was to determine the effect of a supervised 12-week exercise rehabilitation program on skeletal muscle activity and muscle fiber conduction velocity (MFCV) during static and dynamic muscle contractions. **Methods** 9 patients with chronic cardiac disease and 8 matched healthy controls undertook testing before and after a 12 wk period. An electrode array (4 electrodes, 4 mm inter-electrode distance) was placed on the Vastus lateralis of the right leg to measure MFCV. Both groups performed two 5 s isometric maximal voluntary contraction on the Biodex dynamometer, followed by 5 s submaximal contractions at 20 %, 40 %, 60 % and 80 % MVC. Three maximal concentric isokinetic contractions were then performed at 60, 120 and 180 deg/s. **Results** Patients have significantly lower muscle strength ( $183 \pm 18$  Nm) compared to controls ( $230 \pm 38.8$  Nm) ( $p=0.026$ ) and their strength significantly improved after 12 weeks of rehabilitation ( $203 \pm 32$  Nm) ( $p=0.038$ ). MFCV has shown no difference between controls ( $3.4 \pm 0.5$  ms) and patients ( $3.3 \pm 0.8$  ms) in the Pre rehabilitation trial during MVCs and dynamic contractions. Interestingly, the patients have greater EMG activity during submaximal and dynamic contractions before rehabilitation, whereas post rehabilitation the EMG returns to levels of the controls, but with increase in muscle strength ( $p=0.08$ ;  $p=0.07$ ). **Conclusions** The findings of this study suggest that skeletal muscle contractile function was altered so as to produce greater force output but with unchanged relative EMG activity and conduction velocity. This suggests that patients become more efficient in performing the required exercise task following exercise training. **References** 1) Derman W, Whitesman S, Dreyer M, Patel DN, Nossel CJ, Schweltnus MP. ### POST-EXERCISE HYPOTENSION AFTER AEROBIC EXERCISE IN PATIENTS WITH INTERMITTENT CLAUDICATION

CUCATO, G.G., CHEHUEN, M.R., COSTA, L.H.R., CARVALHO, C., JACOB, W., WOLOSKE, N., FORJAZ, C.L.M.

UNIVERSITY OF SÃO PAULO

**Introduction** Post-exercise hypotension has been demonstrated after aerobic exercise in normotensive and hypertensive subjects (Pescatello et al, 2004). However, in patients with intermittent claudication (IC), this phenomenon has been poorly studied. Thus, the aim of the present study was to analyze the occurrence of post-exercise hypotension and its hemodynamic determinants after a bout of aerobic exercise in IC patients. **Methods** Twelve patients underwent two sessions executed in a random order: aerobic exercise (E, 15 2-min bouts of walking on a treadmill) and control (C, 60 min of upright rest). Before and for 60 min after the interventions, blood pressure (BP), heart rate (HR) and cardiac output (CO, CO<sub>2</sub> rebreathing) were measured while subjects rested in supine position. Systemic vascular resistance (SVR) and stroke volume (SV) were calculated. A two-way ANOVA for repeated measures was employed. Data are mean $\pm$ SE. **Results** In comparison with pre-intervention values, systolic, diastolic and mean BP increased significantly after the C session. In contrast, systolic BP decreased, and diastolic and mean BP did not change after the E session, which produced a net reduction of  $-13 \pm 2$ ,  $-6 \pm 2$  and  $-8 \pm 2$  mmHg, respectively. In the sample as a whole, CO decreased while SVR increased significantly and similarly after the interventions in both sessions. Considering individual responses, SVR decreased in 42% of the sample, CO in 25%, and in another 25%, both mechanisms decreased simultaneously. In the C session, the reduction in the CO was due to a decrease in HR, while in the E session it was accompanied by a decrease in SV. **Discussion** The findings of present study show that a session of aerobic exercise promoted post-exercise hypotension in IC patients. The magnitude of BP reduction was similar to the one reported for hypertensive subjects (Pescatello et al, 2004). Thus, these results may have clinical relevance, since hypertension is a common comorbid in this population. The hemodynamic mechanisms of post-exercise BP reduction varied among the patients as already reported for healthy subjects (Forjaz et al., 2004), and

future studies may address the possible determinants of these mechanisms. Financial support: FAPESP (2009/17371-6), CAPES DEMANDA SOCIAL. ### THE EFFECT OF CONTINUOUS AEROBIC EXERCISE ON PEAK OXYGEN UPTAKE IN CABG PATIENTS

SHEIKHSARAF, B., FATHOLLAHI SHOORABEH, F., TARVERDIZADEH, B.

IAU, NAJAFABAD BRANCH

The Effect of Continuous Aerobic Exercise on peak Oxygen Uptake in CABG Patients B.Sheikhsaraf1, F.Fathollahi Shoorabeh2, B. Tarverdi-zadeh3 1-Faculty member of IA University, Najafabad Branch 2-BSc of physical Education, Shahrekord University 4-Faculty member of IA University, Booshehr Branch Abstract Over the last decade, it has become increasingly clear that exercise is good for patients with heart failure. It can reduce symptoms and allowing patients to live more active lives. Increased aerobic exercise capacity appears to reduce cardiovascular mortality and so physical exercise to improve peak oxygen uptake (peak) is strongly recommended. The aim of this study was to assess the effect of continuous aerobic exercise on peak of patients after coronary artery bypass graft (CABG). Subjects were 36 male patients (BMI < 30) who were elapsed 3 months of their open heart surgery. They had no exercise activity, no orthopedics, pulmonary disease. They had no active chest pains or angina and were randomly assigned to one of two groups: a control group (C; n = 18) and a training group (T; n=18). T group exercised 41 minutes continuously at 50-70% of maximum heart rate (50-60% peak) for 8 weeks. peak was determined by ACSM formula. Continuous aerobic exercise has a significant effect on peak of CABG patients ( $p=0.036$ ), while there was no significant change in control group. The results of this study indicate that continuous aerobic exercise can be a method for increasing (peak) in CABG patients and it can reduce the risk of developing or speeding the progression of heart disease. This method can be used as an alternative method for decreasing the side effects of surgery.

### PHYSICAL ACTIVITY AS A MEDIATOR OF QUALITY OF LIFE IN BREAST CANCER PATIENTS ENROLLED IN A DISEASE MANAGEMENT PROGRAM

ECKERT, K.1, HUBER, G.2

1:UNIVERSITY OF LEIPZIG, 2: UNIVERSITY OF HEIDELBERG

Introduction Around 55.000 cases of breast cancer are registered and 18.000 women die due to this disease in Germany every year (Giersiepen et al., 2005). The women diagnosed with breast cancer are abruptly stricken by the psychological strain aside from the physical impairment. Physical activity is related to different aspects of the physical and psychological well-being (Dunlop & Self, 2008). The aim of the study is to evaluate the impact of a multimodal, behavioral-orientated physical activity program on health related quality of life (HRQoL) for women undergoing adjuvant therapy for breast cancer. Methods The study was designed as a classic follow-up intervention study. All participants were tested twice: In the first lesson of the exercise program (t1) and in the 12th and last lesson of the program (t2). At each time point data was taken about HRQoL (Bullinger & Kirchberger, 1998), fatigue and physical activity. Furthermore all the subjects participated in a 2 km walking test. Personal data was also recorded. Results 68 women took part in the program (aged  $64,7 \pm 7,76$ ; diagnosed in month  $45,2 \pm 45,7$ ; BMI  $25,6 \pm 4,37$ ). The following results have been found: • The sample showed clearly deviates in HRQoL from the values of the German norm of healthy women. These differences have been extremely dominant in the subscales ‚physical functioning‘ ( $d=0,58$ ) and ‚emotional roll functioning‘ ( $d=0,64$ ). • Significant and practical meaningful changes can be seen in the subscales ‚general health state‘ ( $N=46$ ,  $p<0,05$ ,  $d=0,23$ ), ‚psychological well-being‘ ( $N=45$ ,  $p<0,05$ ,  $d=0,38$ ) and ‚vitality‘ ( $N=45$ ,  $p<0,05$ ,  $d=0,23$ ). • Further analysis prove that the effects are independent of age ( $p=0,930$ ,  $F=0,148$ ) and of the time point of the diagnosis ( $p=0,173$ ,  $F=1,924$ ). • Having a  $p<0,01$  and an effect size of  $d=0,30$  the improvement of the endurance (2 km walking test,  $N=42$ ) is not only significant but also practical important. Discussion The design of the study does not allow the conclusion of a causal relationship between the participation in an exercise program and the effects demonstrated here. Yet, the effects that have been observed serve as an impulse to initiate further research in this area. The coming studies should have larger sample sizes and should use a control group. This could deliver further affirmation that this sort of exercise program should be standard as an adjuvant therapy for women enrolled in a DMP for breast cancer. ### EFFECTS OF DAILY PHYSICAL ACTIVITY ON FALLS RISK. A COMPARATIVE ANALYSIS BETWEEN INSTITUTIONALIZED AND COMMUNITY-DWELLING ELDERLY ADULTS

CARVALHO, M., FARIA, M., MARQUES, E.A., MOTA, J.

UNIVERSITY OF PORTO

Introduction: Strategies to increase daily physical activity may be viewed as a mean to counteract the high prevalence of falls in elderly subjects, which is an important and increasing single factor associated with disability, injury and death. On the other hand when the elderly have reduced autonomy and consequent need of institutionalization the social cost to support this prevalent scenario continues to rise. Thus, the present study aimed to evaluate the effect of daily physical activity, on balance, lower limbs strength and fear of falling in non-institutionalized (NI) and institutionalized (I) elderly subjects. Methods: This cross-sectional study included 40 institutionalized and 38 community-dwelling older adults aged 65 to 90 years. For data collection we used a socialdemographic questionnaire, the Tinetti Scale for balance assessment, the Falls Efficacy Scale (FES) to assess fear of falling based on the operational definition of fear as 'low perceived self-efficacy or confidence at avoiding falls' (Tinetti et al,1990) and validated for Portuguese population, and 30 seconds chair sit-to-stand for lower limbs strength assessment. Moreover, accelerometers (Actigraph GT1M) were used by the sample during 7 consecutive days for daily physical activity assessment. Data were verified for normality of distribution by Kolmogorov-Smirnov test. Impaired Student's t-test was used to compare means between groups and when the variables departed from normality, the Mann-Whitney test was used instead. Results: Data showed that the institutionalized older adults present lower daily physical activity (MVPA: I-  $250,11 \pm 218,52$  min/week vs NI-  $543,37 \pm 237,73$ ;  $p=0,000$ ) as well as less balance (Static balance: I-  $9,36 \pm 3,40$  vs NI-  $12,86 \pm 2,76$ ,  $p=0,000$  and Dynamic balance: I-  $8,05 \pm 2,79$  vs NI-  $11,16 \pm 1,90$ ;  $p=0,000$ ), increased fear of falls (I-  $63,93 \pm 20,49$  vs NI-  $88,81 \pm 14,51$ ;  $p=0,03$ ) and lower muscle strength (I-  $10,70$  reps vs  $18,76$  reps,  $p=0,00$ ) compared to non-institutionalized elderly peers. Conclusions: These results suggest that increase daily physical activity habits may be an effective strategy to positively influence fall risk in elderly subjects. Furthermore, this study supports the

idea that health care homes and institutionalizations for older subjects should promote Physical Activity instead of restricted it in order to prevent frailty. Mota are supported by grants from Portuguese FCT (SFRH/BD/36319/2007 and SFRH/BSAB/1025/2010 respectively).

### LONG-TERM SQUARE-STEPPING EXERCISE PROGRAMME AND ITS EFFECTS ON FUNCTIONAL FITNESS IN COMMUNITY-DWELLING ELDERLY PERSONS

SHIGEMATSU, R.1, OKURA, T.2, NAKAGAICHI, M.3, NAKATA, Y.2

1: FACULTY OF EDUCATION, MIE UNIVERSITY, 2: GRADUATE SCHOOL OF COMPREHENSIVE HUMAN SCIENCES, UNIVERSITY OF TSUKUBA, 3: RESEARCH AND DEVELOPMENT CENTER FOR HIGHER EDUCATION, NAGASAKI

**Introduction** We have previously developed a novel exercise programme called the Square-Stepping Exercise (SSE) (Shigematsu and Okura, 2006). Walking involves forward-stepping movements, while SSE involves step movements in multiple directions. We confirmed the effects of SSE on the functional fitness of elderly persons in a 3-month randomised controlled trial. However, it is not clear whether SSE is consistently acceptable and effective is not known. The purpose of the study was to assess the acceptance of SSE and its effect on the functional fitness of elderly persons. **Methods** Community-dwelling elderly persons aged 69–77 years were randomly distributed into an SSE group (n = 32) and a walking group (n = 31). They participated in a 3-month exercise intervention programme with SSE and walking, respectively. After the programme, many participants in each group established autonomous exercise groups and continued to perform SSE or walk regularly. Functional fitness was assessed via physical performance tests 1 and 4 years after the programme. Results Of the SSE participants, 22 (69%) and 20 (63%) had been performing SSE regularly at 1 and 4 years, respectively. Of the walking participants, 20 (65%) and 20 (65%) continued walking regularly at 1 and 4 years, respectively. The number of participants in the SSE group who continued SSE did not differ significantly from those in the walking group who continued walking. Stepping agility and chair stands in both groups improved significantly from the baseline (beginning of the 3-month programme) at the 1- and 4-year assessment, but handgrip strength decreased significantly ( $P < 0.05$ ). Tandem walking, simple reaction time, choice reaction time, and walking agility improved significantly only in the SSE group at the 1-year assessment ( $P < 0.05$ ). In this group, the improvements in walking agility and choice reaction time were sustainably maintained at the 4-year assessment. Significant improvement in functional reach at 1-yr in both groups was attenuated at 4-yr. **Discussion** SSE seems sustainably acceptable among elderly persons because the percentage of adherence to SSE was similar to that to walking. Improvement in functional fitness was significantly higher in the SSE group than in the walking group. This may be because SSE involves stepping in multiple directions. Therefore, we recommend SSE as an alternative exercise programme, which is acceptable among elderly persons and has a significant long-term effect on the functional fitness of lower extremities. ### REGULAR LEVEL AND DOWNHILL TREADMILL WALKING AT SELF-SELECTED SPEED IMPROVES WALKING ABILITY AND PREDICTED AEROBIC CAPACITY IN OLDER PEOPLE

CLEMENTS, R.E.1, WILLEMS, M.E.T.1, GAULT, M.L.2

1: UNIVERSITY OF CHICHESTER, UK, 2: UNIVERSITY CAMPUS SUFFOLK, UK

**Introduction** Older women are able to self-select treadmill walking speeds that meet the recommended physical activity intensity guidelines (Haycock et al., 2009). This study examined the effects of regular level and downhill treadmill walking (i.e. concentric and eccentric endurance exercise) on maximal walking speed, 1-mile walk and predicted maximum oxygen uptake. **Methods** Twenty-four community-dwelling people (12 men, 12 women,  $67 \pm 4$  yrs,  $75 \pm 14$  kg) volunteered for the study. Self-selected level walking speed was determined by participants as a speed which could be maintained for 30-mins. Subjects began walking at  $2.5 \text{ km} \cdot \text{hr}^{-1}$ , increments of  $0.2 \text{ km} \cdot \text{hr}^{-1}$  were employed every 30-secs. Self-selected speed was readjusted at weeks 4 and 8. Participants walked  $3 \times 30$ -min on a level (LW: 0%) or downhill (DW: -10%) gradient every week, full adherence was required for progression. Completion rates were 9 (LW) and 10 (DW) after 12 weeks. Maximal walking speed over 10-m and a 1-mile indoor walk predicting maximum oxygen uptake (Fenstermaker et al., 1992) were performed at baseline, 4, 8 and 12 weeks. Physiological responses during the 1-mile walk were recorded with a portable metabolic system (Cosmed K4b2; Gault et al., 2009). Results Treadmill walking speeds were similar at baseline (LW:  $1.18 \pm 0.11 \text{ m} \cdot \text{s}^{-1}$ ; DW:  $1.26 \pm 0.16 \text{ m} \cdot \text{s}^{-1}$ ) and increased ( $P < 0.0001$ ) equally in both groups ( $P > 0.2$ ) at all time points. Maximum 10-m walking speeds were also similar at baseline (LW:  $2.39 \pm 0.38 \text{ m} \cdot \text{s}^{-1}$ ; DW:  $2.40 \pm 0.33 \text{ m} \cdot \text{s}^{-1}$ ) with equal increases at 4, 8 and 12 weeks ( $P < 0.0001$ ). Mean one-mile walking speed was  $1.78 \text{ m} \cdot \text{s}^{-1}$  in both groups at baseline, this increased significantly in both groups after 8 ( $P < 0.0001$ ) and 12 weeks ( $P < 0.0001$ ). Predicted maximum oxygen uptake increased after 8-weeks of training in both groups (LW:  $23 \pm 15\%$ ; DW:  $23 \pm 30\%$ ,  $P < 0.0001$ ) with no further increases measured at 12 weeks ( $P > 0.2$ ). **Discussion** Older men and women who engaged in regular downhill and level treadmill walking increased maximal walking speed after only 4 weeks; whereas the pace they could maintain over 1-mile increased after 8 weeks. Eccentric endurance exercise performed with a reduced cardiovascular load (Clements et al., 2011) resulted in similar aerobic adaptations to level treadmill walking. Therefore, downhill treadmill walking at a self-selected speed may serve as a novel exercise intervention to induce functional adaptations in elderly people. ### IS IT TRUE THAT WALK WITH DOG INCREASES BOTH SEX ADOLESCENTS PHYSICAL ACTIVITY LEVEL?

FIGUEIRA JUNIOR, A., CESCHINI, F., ALVARES, L., ROCHA FERREIRA, M.B.

SÃO JUDAS TADEU UNIVERSITY

**Introduction** Physical activity is recognized as important behavior related to health for different age groups. Many adolescents do not reach enough amount of daily physical activity to prevent chronic diseases (Ceschini et al, 2009). Simple activities like walking and biking are recommended to increase physical activity level (PAL). Thus this paper aimed to determine the influence of active (ABe) and sedentary (SBe) behaviors in both sex adolescents PAL. **Methods** 136 adolescents boys and 126 girls living at São Paulo City-Brazil (15.3+1.1 years old boys and 15.6+1.3 years old girls) answered the International Physical Activity Questionnaire (IPAQ- short version 8). IPAQ determines the PAL accordingly total time related to body movement (locomotion, exercise program at leisure time, dog walking, bike riding). The classifi-

cation in active (AC) and insufficient active (INA) adolescents followed Ceschini and Figueira Junior (2011): AC-adolescent that accumulate more than 300 min/week of PA; INA-adolescent that accumulate less than 300 min/week of PA. Active behavior (ABe) was walk with the dog (min/week) and riding a bike (min/week). Sedentary behavior (SBe) chosen was TV watching (min/week) and computer use (min/week). Student Paired t Test compared AC and INA boys and girls for ABe and SBe. The level of significance was  $p < .01$ . Results Data evidenced that both sex adolescents accumulated in average 94.8 min/week in ABe and 475.1 min/week in SBe. AC boys spent 100.2 min/week in ABe while AC girls 143.3 min/week. INA boys spent 100.1 min/week in ABe and INA girls 41.2 min/week (ABe). Discussion These data evidenced the importance of walk with dog and bike riding as ABe for PAL. Both AC and INA boys presented similar contribution of dog walking and bike riding in PAL. However INA girls presented lower adherence in ABe activities than AC girls, and AC and INA boys. These data allow us to conclude that ABe contributed to total PAL in AC adolescents. SBe was higher in AC group, but did not decrease the PAL. Data presented that PAL was higher to those ones that walked with dog and ride a bike. We suggest to stimulate easy-daily activities as walking for increasing PAL (Gorely, et al, 2009). ## THE EFFECT OF DEPRESSION ON THE PARTICIPATION IN THE EXERCISE HABITS IN COMMUNITY-DWELLING JAPANESE OLDER PEOPLE

KOZAKAI, R., ANDO, F., KIM, H.Y., LEE, S., NISHITA, Y., TANGE, C., SHIMOKATA, H.

*NATIONAL CENTER FOR GERIATRICS AND GERONTOLOGY*

Introduction: Physical activity is one of the most important health behaviors especially in later life. Previous studies found that physical activity was associated with prevention and improvement of depression. Although the association may be bidirectional, few studies examined the effect of depression on participation in regular physical activity in older people. The purpose of this study was to evaluate the impact of depression on participation in exercise habits in community-dwelling Japanese older people. Methods: The subjects consisted of 523 men and 461 women who were the participants aged 60 years and over in the 4th study of the National Institute for Longevity Sciences - Longitudinal Study of Aging (NLS-LSA). Exercise habits were assessed by questionnaire and interview. Physical activities or sports for 20 minutes or more, at least once a week and over 1 year were defined as an exercise habit. Depression was assessed by the Center for Epidemiologic Studies Depression (CES-D) scale. The score of 16 or over was defined as depression. Sociodemographics, health conditions and lifestyle factors were checked by questionnaire. Multiple logistic regression models were used to estimate the effect of depression on participation in exercise habits. Both the unadjusted model and the adjusted model for all potential confounders were performed in men and women separately. Significant probability levels were considered to be less than 0.05. Results: The participation rate in exercise habits was 65.4% in men and 57.1% in women. The prevalence of depression in the subjects with and without exercise habits was 10.7 % and 19.9 % in men and 16.0 % and 20.9 % in women, respectively. Men with exercise habits had a significantly lower prevalence rate of depression than those without exercise habit, whereas there was no significant difference in depression by exercise habits in women. In the unadjusted logistic regression model, exercise habit was significantly influenced by depression in men (OR 0.48, 95%CI 0.29-0.80). After adjusting for all potential confounders, the risk of depression on exercise habit was not significant in men. In women, there were no significant associations between depression and exercise habit in both models. Conclusion: Depression was cross-sectionally associated with lower participation in exercise habits in men aged 60 years and over. However, the association was modified by the confounders such as lifestyle factors and health conditions. In women, depression may not be associated with participation in exercise habit.

## ARE CURRENT CARBOHYDRATE RECOMMENDATIONS FOR ENDURANCE EXERCISE APPROPRIATE AND ATTAINABLE FOR MOUNTAIN MARATHONERS?

MAHON, E.A., DAVIES, I.G., STOTT, T.A., HACKETT, A.F.

*LIVERPOOL JOHN MOORES UNIVERSITY*

ARE CURRENT CARBOHYDRATE RECOMMENDATIONS FOR ENDURANCE EXERCISE APPROPRIATE AND ATTAINABLE FOR MOUNTAIN MARATHONERS? EA Mahon, IG Davies, TA Stott & AF Hackett, Liverpool John Moores University Introduction There is plentiful evidence that increasing available carbohydrate (CHO) enhances performance during exercise, but limited literature exists on the requirements of ultra-endurance athletes. Intakes of 30-60 g CHO per hour are currently recommended (American College of Sports Medicine, 2009), but data suggests mountain marathoners typically consume less than this (Kruessman et al., 2005). The purpose of this study was to investigate if the provision of written dietary guidelines is effective in helping mountain marathoners to meet these recommendations and whether it is associated with an improvement in performance. Methods An intervention study was performed using male participants entered in the Longmynd Hike (50 mile race). The intervention group (n = 8, mean age: 42 (SD: 13) y, body mass index (BMI): 24.0 (SD: 3.4) kg/m<sup>2</sup>) received written dietary advice for CHO consumption and the control group (n = 8, mean age: 44 (SD: 18) y, BMI: 24.1 (SD: 1.6) kg/m<sup>2</sup>) received no advice. Participants were assigned to each group by stratified random sampling. Participants completed a weighed food inventory of all items consumed during the event and provided a rating of perceived exertion (RPE) using the Borg 6-20 scale (Borg, 1970). All data are expressed as means (SD), statistical significance  $p < 0.05$ . Results Total CHO consumption was significantly different between groups [intervention: 670 (120) g, control: 491 (176) g,  $t = 2.39$ ,  $p = 0.034$ ]. All participants in the intervention group consumed within the recommended range [mean: 40 (10) g/h, range: 30-57 g/h], in comparison 62.5% of the control group consumed < 30g CHO/h [mean: 31 (14) g/h, range: 16-51 g/h]. CHO (g/h) showed a strong, positive correlation with performance ( $r = 0.622$ ,  $p = 0.017$ ,  $n = 16$ ). There was no significant difference in overall performance between the intervention and control groups [mean completion time: 17.0 (3.4) h and 16.9 (2.8) h, respectively], however RPE was significantly higher in the control group [intervention: 15 (2.0), control: 18 (1.2),  $t = -2.97$ ,  $p = 0.012$ ]. Discussion These findings suggest that written advice can be effective in aiding athletes to meet dietary guidelines. As CHO appears to

have a strong association with performance in such events, and the quantities consumed by the intervention group were still at the lower end of the recommendations, it may be beneficial to promote higher intakes of 1 g/kg/h closer to the maximum CHO oxidation rate (Hawley et al., 1992). ### **ADDITION OF CAFFEINE TO POST-EXERCISE CARBOHYDRATE FEEDING IMPROVES SUBSEQUENT HIGH-INTENSITY INTERVAL RUNNING CAPACITY COMPARED WITH CARBOHYDRATE ALONE**

TAYLOR, C., HIGHAM, D., CLOSE, G., MORTON, J.

LIVERPOOL JOHN MOORES UNIVERSITY

The aim of this study was to test the hypothesis that the addition of caffeine to post-exercise carbohydrate feedings improves subsequent high-intensity interval running capacity compared with carbohydrate alone. In a repeated measures design, six men performed a glycogen-depleting exercise protocol until volitional exhaustion in the morning. Immediately after and at 1, 2 and 3 h post-exercise, participants consumed either: 1) 1.2 g.kg<sup>-1</sup> body mass (CHO) of a 15% carbohydrate solution, 2) a similar CHO feeding protocol but with addition of 8 mg.kg<sup>-1</sup> body mass of caffeine (CHO+CAFF) or, 3) an equivalent volume of flavoured water only (WAT). After the 4 h recovery period, participants performed the Loughborough Intermittent Shuttle Test (LIST) to volitional exhaustion as a measure of high-intensity interval running capacity. Average blood glucose values during the 4 recovery period were higher in the CHO conditions ( $P < 0.005$ ) compared with the WAT trial ( $4.6 \pm 0.3$  mmol.L<sup>-1</sup>), although there was no difference ( $P = 0.46$ ) between CHO ( $6.2 \pm 0.8$  mmol.L<sup>-1</sup>) and CHO+CAFF ( $6.7 \pm 1.0$  mmol.L<sup>-1</sup>). Exercise capacity during the LIST was significantly longer in the CHO+CAFF trial ( $48 \pm 15$  min) compared with the CHO ( $32 \pm 15$  min,  $P = 0.04$ ) and WAT conditions ( $19 \pm 6$  min,  $P = 0.001$ ). All six participants improved performance in CHO+CAFF compared with CHO (95% CI for mean difference = 1-32 min). We conclude that addition of caffeine to post-exercise CHO feeding improves subsequent high-intensity interval running capacity, which may be related to higher rates of post-exercise muscle glycogen re-synthesis previously observed during similar feeding conditions (Pedersen et al. 2008).

### **PERFORMANCE AND METABOLIC EFFECTS OF HIGH AND LOW GLYCAEMIC INDEX MEALS PRIOR TO SOCCER SPECIFIC EXERCISE**

HULTON, A., MACLAREN, D.P.M., GREGSON, W., DORAN, D.

LIVERPOOL JOHN MOORES UNIVERSITY

**Introduction** Pre-exercise meals or single foods containing low glycaemic index (LGI) carbohydrates (CHO) have been shown to enhance performance prior to prolonged steady state exercise compared to high glycaemic index (HGI) CHO. This study investigated the impact of HGI and LGI pre-exercise meals on simulated-soccer activity. **Methods** Nine male recreational football players performed a football specific protocol followed by a 1 km time trial 3 ½ h after ingesting one of two isoenergetic test meals (HGI: 870.3 kcal, LGI: 889.5 kcal), which were either HGI (GI: 80) or LGI (GI: 44). Plasma glucose, non-esterified fatty acids (NEFA), glycerol,  $\beta$ -hydroxybutyrate, lactate and insulin were assessed before, during, and after the exercise bout, whilst rates of CHO and fat oxidation were determined at four time points during the protocol along with heart rate (HR), rating of perceived exertion (RPE) and ratings of hunger and fullness. **Results** No significant differences were found for the 1km time trial (LGI:  $210.2 \pm 19.1$  s; HGI:  $215.8 \pm 22.6$  s), nor for any of the other variables measured ( $P < 0.05$ ) apart from a significant condition effect with NEFA (LGI:  $1.69$  mmol.L<sup>-1</sup>; HGI:  $1.33$  mmol.L<sup>-1</sup>) and significant interaction effects observed for glucose,  $\beta$ -hydroxybutyrate and lactate ( $P > 0.05$ ). **Discussion** These findings suggest that the type of CHO ingested in a pre-match meal has no significant impact on metabolic responses during 90 minutes of football simulated activity or on a subsequent performance test.

### **HIGH AND LOW CARBOHYDRATE DIETS AND DISTANCES COVERED IN SOCCER**

SOUGLIS, G.A.1, CHRYSSANTHOPOULOS, C.1, TRAVLOS, K.A.2, GISSIS, I.3, PAPADOPOULOS, C.3, SOTIROPOULOS, A.1

UNIVERSITY OF ATHENS

1: Faculty of Physical Education and Sports Science, University of Athens (Athens, Greece) 2: Department of Sports Organization and Management, University of Peloponnese, (Sparta - Laconias, Greece) 3: Department of Physical Education and Sport Science of Serres, Aristotle University of Thessaloniki (Thessaloniki, Greece) **Introduction** The intake of carbohydrate (CHO) in soccer may reduce the negative effects of fatigue (FIFA/F-MARC 2006). This study compared the distance covered during soccer following a high or a low CHO diet. **Methods** Twenty two professional male soccer players formed two teams of similar age, body characteristics, and training experience [Team A:  $24 \pm 0.7$  yrs;  $180 \pm 2$  cm;  $75.7 \pm 1.4$  Kg;  $10.6 \pm 0.3$  %;  $12.6 \pm 0.7$  yrs Vs. Team B:  $24.5 \pm 0.8$  yrs;  $180 \pm 2$  cm;  $76 \pm 1.4$  Kg;  $10.7 \pm 0.3$  %;  $13.5 \pm 0.9$  yrs, for age, height, body mass (BM), % body fat, and training experience respectively; mean  $\pm$  SE]. The teams played against each other twice with a week interval, following either a high (8 g CHO/ Kg BM) (HC) or a low (3 g CHO/ Kg BM) CHO diet (LC) for 3 days before each game. The goalkeepers were excluded from dietary intervention and data collection procedures. In the 1st match team A followed the HC diet and team B the LC diet, whereas in the 2nd match the treatment was reversed. Environmental conditions were similar between the two games (1st game:  $25^\circ\text{C}$ , 23% vs. 2nd game:  $26.2^\circ\text{C}$ , 29%, for temperature and humidity respectively), while fluid intake was provided ad libitum. Distances covered, running speeds, and heart rates during the games were recorded using GPS technology (GARMIN 305). **Results** When players followed the HC treatment won the matches [Team A vs. Team B: 3-1 (half time: 1-0) for the 1st game and Team A vs. Team B: 1-2 (half time: 0-0) for the 2nd game]. Every player covered a greater total distance in HC compared to the distance covered in LC (HC:  $9380 \pm 98$  m vs. LC:  $8077 \pm 109$  m;  $p < 0.01$ ). Also, when the total distance was analysed for different speeds of movement, it was observed that all distances covered from easy jogging ( $2$  m.sec<sup>-1</sup>) to sprinting ( $> 6.72$  m.sec<sup>-1</sup>) were higher in HC compared to LC ( $p < 0.01$ ). Furthermore, mean heart rate was higher in HC ( $169 \pm 1$  b.min<sup>-1</sup>) compared to LC ( $164 \pm 1$  b.min<sup>-1</sup>) condition ( $p < 0.01$ ). **Discussion** The data show that the HC diet helped players to cover a greater distance compared to LC, something that may have contributed to winning. **References** FIFA/F-MARC (2006). *J Sports Sci*, 24, 663-664.

## EFFECTS OF CARBOHYDRATE-ELECTROLYTE PLUS CAFFEINE INGESTION ON PERFORMANCE AFTER A ROLLER HOCKEY GAME

TEIXEIRA, V.H.1,2, LIMA, S.C.1, OLIVEIRA, E.M.3

1: FACULTY OF NUTRITION AND FOOD SCIENCES OF UNIVERSITY OF PORTO, PORTUGAL, 2: RESEARCH CENTRE FOR PHYSICAL ACTIVITY AND LEISURE, UNIVERSITY OF PORTO, PORTUGAL, 3: FACULTY OF SPORT SCIENCES OF UNIVERS

**Introduction** A roller hockey game is a fast-paced highly skill game, characterised by short duration high intensity efforts, with variable periods of recovery, played indoors in halves of 25min. It challenges athletes' nutritional status, which if not properly assured increase the risk of impaired performance. This study compared the effect of ingesting a carbohydrate-electrolyte solution alone (CE) or with caffeine added (CEC) with water (W) on hydration status, and physical, technical and cognitive performances after a roller hockey game. **Methods** In a randomized, double-blind, crossover, 12 male well-trained roller hockey players ( $23.6 \pm 4.9$  yr) performed, in 3 different occasions separated by a week, a 60 min simulated roller hockey game ( $\sim 56\% \text{VO}_{2\text{max}}$ ), followed by a set of technical (dribble, pass, reception, shooting, control and ball possession) and physical (strength, speed, acceleration, agility and reaction) drills ( $\sim 32\% \text{VO}_{2\text{max}}$ , 60 min) that ended with a YoYo Intermittent Endurance Test Level 2 ( $\sim 76\% \text{VO}_{2\text{max}}$ , 8 min). Athletes ingested W (0.38mg/100ml Na), CE (7% CHO, 68mg/100ml Na) or CEC (25mg caffeine/100ml) before (5 ml/kg), every 15 min during ( $4 \times 2$  ml/kg), and every 20 min after ( $3 \times 2$  ml/kg) the roller hockey game. Body weight lost, sweat rate, urine colour, rating of perceived exertion (RPE) and mood states (BRUMS) were determined. Results Athletes reported a higher RPE with W ( $13.75 \pm 1.06$ ) compared with CE ( $12.75 \pm 1.85$ ) and CEC ( $11.83 \pm 1.4$ ) immediately after the game ( $p=0.021$ ) that lost statistical significance after the drills and YoYo tests. The squat jump ( $38.9 \pm 3.8$  cm) and agility and reaction ( $35.5 \pm 1.4$  sec) were significantly improved in the CEC trial than with W ( $34.8 \pm 3.8$  cm and  $38.0 \pm 1.5$  sec) and CE ( $38.0 \pm 3.9$  cm  $36.6 \pm 2.2$  sec). Athletes reported lower levels of cognitive fatigue after the exercise protocol ( $p=0.03$ ) with CEC ( $-0.67$ ) than with CE ( $+0.08$ ) and W ( $+0.83$ ). The distance covered on the YoYo test increased ( $26.2\%$ ) non-significantly ( $p=0.058$ ) with CEC in comparison with W. It was observed an almost statistical significant ( $p=0.058$ ) negative correlation ( $r=-0.319$ ) between sweating rate and performance in the YoYo test. There were no significant differences in fluid intake, body weight loss, sweat rate, urine colour, skill parameters and the other physical variables between the 3 drinks. **Conclusions** The intake of carbohydrate-electrolyte solutions, with or without caffeine, appears to decline the perception of fatigue after exercise. Caffeine seems to further improve explosive power and reaction time and agility without adversely affecting hydration status.

## THE EFFECTS OF INGESTING A SOLID VS. A LIQUID CARBOHYDRATE SUPPLEMENT ON ERGOMETER ROWING PERFORMANCE.

KIRK, T., SIMPSON, C.

OXFORD BROOKES UNIVERSITY

**Introduction.** Research indicates that carbohydrate (CHO) ingestion can improve cycling and running performance in events lasting longer than approximately 45-min (Jeukendrup et al., 1997; Rollo & Williams, 2009). Furthermore, in cycling exercise, the form of the ingested CHO does not affect its oxidation rate (Pfeiffer et al., 2010). However, research concerning the effects of CHO, either in a liquid or a solid form in rowing is limited and even fewer studies have investigated the impact on performance. This study evaluated the effects of solid or liquid CHO ingestion on ergometer rowing TT performance. **Methods.** On three occasions, five oarsmen (mean  $\pm$  SD age  $23 \pm 3$  y, height  $184.0 \pm 5.1$  cm, weight  $83.7 \pm 6.7$  kg,  $\text{VO}_{2\text{max}}$   $5.1 \pm 0.5$  L.min<sup>-1</sup>) performed 45-min of rowing at 60% of  $\text{VO}_{2\text{max}}$  on a Concept-2 ergometer, followed by a 5-km TT. Ten minutes before and immediately after the 45-min preload, participants ingested either: 900ml (600ml + 300ml) of a 6% CHO solution (DRINK), 900ml of a flavoured placebo beverage (PLA) or an isoenergetic solid CHO supplement with 100ml of PLA (SOLID) in a randomised order. **Statistics.** Heart rate (HR) and rating of perceived exertion (RPE) were analysed using a two way (trial  $\times$  time) repeated measures ANOVA. Time trial data (shown as mean  $\pm$  90% confidence limits) were analysed using the methods of Batterham & Hopkins (2006). **Results.** Ingestion of DRINK improved TT time by  $2.5 \pm 1.5\%$  (highly likely to improve performance) and  $1.9 \pm 2.6\%$  (likely to improve performance) compared to PLA and SOLID, respectively. There were no differences in HR or RPE between trials, although there was a trend for a higher mean HR during the TT in DRINK ( $175 \pm 8$ ,  $176 \pm 7$  and  $180 \pm 5$  bpm, for PLA, SOLID and DRINK, respectively,  $P=0.052$ ). **Discussion.** Ingestion of DRINK improved 5-km rowing TT time compared to both PLA and SOLID. It has been proposed that the presence of CHO in the mouth stimulates oral CHO receptors, which may have central effects (Chambers et al., 2009). Improvements in TT performance following CHO ingestion may be due to central effects of CHO increasing motor drive, leading to a higher power output, and thus HR. This may explain the trivial effect of SOLID ingestion, as oral exposure to CHO may have been limited in comparison to ingestion of 900ml of DRINK. Alternatively, the lower fluid content may have impaired performance due to cardiovascular or thermoregulatory limitations. **References.** Batterham AM & Hopkins WG (2006). ## CARBOHYDRATE INGESTION DURING A 5KM SWIM: EFFECTS ON METABOLISM AND PERFORMANCE

PARASKEVOPOULOU, E.1, TOUBEKIS, A.1, SARRA, K.2, NAFPAKITOU, D.1, KOSTOULAS, I.3, VEZOS, N.4, SOULTANAKIS, H.1

1:FACULTY OF P.E.,(UNIVERSITY ATHENS), 2:MEDICAL SCHOOL (ATHENS), 3:GREEK MILITARY ACADEMY 4: HELLENIC NAVAL ACADEMY

**Introduction** Prolonged swimming performance may decrease because of reduced carbohydrate stores, while muscle injury may occur depending on the intensity of exertion (Smith et al., 2002). The aim of this study was to determine whether carbohydrate consumption during a 5km swim would affect performance, glucose and lactate levels and the concentration of cytokine IL-6 which increases with fatigue and hypoglycemia (Krook A., 2008). **Methods** Ten open water swimmers (age:  $43 \pm 7.6$  yrs,  $\text{VO}_{2\text{peak}}$ :  $49 \pm 11$  ml/kg/min) performed a 5km swimming trial under two experimental conditions in a double blind cross over repeated measures design. At 1.5km in a brief 20s break they consumed either a maltodextrin supplement containing 0.5 g of glucose/kg BW in an aqueous concentration of 35% carbohydrate (C) or a placebo of equal volume (P). Venous blood samples were obtained before and after both trials to determine glucose, lactate and IL-6 concentrations. **Results** Performance was similar between C and P conditions ( $5306 \pm 494$  vs.  $5404 \pm 598$ s,  $p>0.05$ ). When comparing the first to the fifth 1km split, performance was decreased by  $2.9 \pm 4.6\%$  in the C and by  $9.5 \pm 10\%$  in the P trial ( $p>0.05$ ). Blood lactate and blood glucose concentrations were increased after each trial compared to resting values ( $p<0.05$ ) and this was more evident in the C condition. Interleukin-6 (IL-6) after the 5km trials was unchanged compared to resting values and similar between conditions. **Discussion** Carbohydrate supplementation during a 5km swim didn't significantly improve performance, despite showing trends of

maintaining velocity on the last 1km. High blood glucose levels after supplementation -a sign of increased glucose availability- is perhaps the reason for maintaining faster times in the latter part of the C trial as previously shown in cycling (Coyle et al. 1986). The low levels of lactate post exercise and the lack of changes in the IL-6 levels indirectly reflect the low intensity of swimming in both trials (<70% of maxHR), that wasn't adequate to challenge carbohydrate stores. ### **INFLUENCE OF CARBOHYDRATE SUPPLEMENTATION ON OVERTRAINING MARKERS IN ELITE RUNNERS DURING INTENSIVE TRAINING**

SOUSA, M.V.1, MADSEN, K.2, FUKUI, R.1, SANTOS, A.1, SILVA, M.E.R.1

1: LIM-18 FMUSP (SÃO PAULO, BRAZIL); 2: DEPARTMENT OF SPORTS SCIENCE AU (AARHUS, DENMARK)

**Introduction:** Combining a comprehensive training program with inadequate recovery periods and diet can result in overtraining syndrome, with consequent damage to athletic performance (Angeli et al. 2004). Therefore, the aim of this study was to evaluate the influence of carbohydrate supplementation on markers of overtraining for long distance runners undergoing an intensive training program. **Methods:** Twenty-four male elite runners ( $28.0 \pm 1.2$  years) who took part in overload training for 8 days followed by a high intensity intermittent running protocol (10x800m) on the 9th day, were randomly assigned to 2 groups (CHO-group and CON-group) using a double-blind design. The two groups were allotted isocaloric diets whereas one group ingested maltodextrin as a carbohydrate solution (CHO-group) during every training session and the other group was supplied with a placebo solution (CON-group). **Results:** After 8 days of intensive training LDH baseline levels remained constant in the CHO group and increased in the CON group. On the 9th day LDH concentrations were lower in the CHO group than in the CON group post 10x800m. CHO ingestion attenuated the increase of free plasma DNA post 10x800m ( $48240.3 \pm 5431.8$  Allels/ml) when compared to the CON group ( $73751.8 \pm 11546.6$  Allels/ml,  $p < 0.01$ ). Leukocyte counts were attenuated in the CHO group following 10x800m when compared with the CON group and at the 80 min of the recovery period. Cortisol levels were lower in the CHO group post 10x800m than CON group. **Discussion:** CHO ingestion reduced exercise-induced stress hormone evidenced by a lower cortisol response after 10x800m and at 80 min of the recovery period (de Sousa et al. 2010). This might explain the findings of the present study, regarding attenuation in the circulating concentration of free-plasma DNA, LDH and leukocytes after 10x800m in the CHO group. **Conclusion:** Our findings showed that carbohydrate beverage resulted in less DNA damage and attenuation of conventional indices of overtraining so providing a better recovery during intensive training. ### **EVALUATION OF THE EFFECTS OF CARBOHYDRATE SUPPLEMENTS VARYING IN MOLECULAR WEIGHT ON REPEATED SPRINT PERFORMANCE AFTER SHORT TERM RECOVERY FROM INTERMITTENT EXERCISE**

HIGGINS, M.F., MACLAREN, D.P.M

LIVERPOOL JOHN MOORES UNIVERSITY

**EVALUATION OF THE EFFECTS OF CARBOHYDRATE SUPPLEMENTS VARYING IN MOLECULAR WEIGHT ON REPEATED SPRINT PERFORMANCE AFTER SHORT TERM RECOVERY FROM INTERMITTENT EXERCISE** Higgins, M.F (1,2), MacLaren, D.P.M (1) 1: Liverpool John Moores University (UK) 2: University of Coventry (UK) **Introduction** In professional sports, such as rugby union and soccer, players frequently train more than once a day, with training sessions usually two to three hours apart. Therefore, recovery between sessions is crucial if training in the second bout is to be maximised. This study evaluated the effects of two carbohydrate supplements, of different molecular weight (High; HMW and Low; LMW), on repeated sprint performance after a short (3-hour) recovery period from an initial strenuous bout of high-intensity intermittent exercise. **Methods** Six healthy, active males performed 60 minutes of high-intensity shuttle running (LIST; Nicholas et al. 2000) followed by three hours seated recovery. Participants then completed a further 30 minutes high-intensity shuttle running and a bout of six single sprints around a multi-directional course. During recovery, using a double blind and counterbalanced administration, participants consumed two 1 L (10%) solutions of the LMW or HMW solutions and a small isoenergetic meal. Performance was measured as the cumulative sprint time for: the twenty sprints during the post recovery shuttle running and six multidirectional sprints. **Results** No significant difference was apparent for the post recovery cumulative sprint time ( $51.7 \pm 2.3$  s;  $52.2 \pm 2.4$  s;  $P > 0.05$  for LMW and HMW respectively). However, cumulative sprint time for repeated multi-directional sprinting was 3% faster after the LMW solution ( $21.1 \pm 1.1$  s vs.  $21.8 \pm 0.7$  s,  $P < 0.05$ ). **Discussion** Ninety minutes of high intensity shuttle running results in significant depletion of muscle glycogen although higher in type II than type I fibres (Nicholas et al. 1999). With lower glycogen re-synthesis in type II fibres during recovery, reliability on type II fibres during subsequent exercise and no evidence of hypoglycaemia, it is likely that differences in muscle fibre type replenishment and thus substrate availability played some role in the contrasting results to similar previous research (Casey et al. 1995; Stephens et al. 2008). Although, the exact mechanism(s) remains to be elucidated these results may have practical implications for athletes engaging in repeated daily bouts of high intensity intermittent exercise which include multi-directional sprinting. ### **THE EFFECT OF CARBOHYDRATE BAR INGESTION ON PHYSIOLOGICAL AND METABOLIC RESPONSES TO PROGRESSIVE EXERCISE**

KONSTANTAKI, M., PETERS, G.

BUCKINGHAMSHIRE NEW UNIVERSITY

Carbohydrate feedings in the hour before exercise have been shown to improve exercise performance (Hargreaves et al., 2004). However most studies have used carbohydrate drinks of different concentration, prolonged exercise (over 60 min) and highly trained subjects. The purpose of this study was to assess the effects of a new, all-natural ingredients carbohydrate bar (The Buzz®) on physiological and metabolic responses to exercise in trained athletes and physically active individuals. Eight male and two female subjects aged 18-47 years participated in the study. The sample included four male professional rugby league players (mean  $\pm$  SD; age:  $18.3 \pm 1.3$  years, stature:  $190.2 \pm 5.6$  cm, body mass:  $101.1 \pm 8.7$  kg), four triathletes (three males; mean  $\pm$  SD; age:  $41.6 \pm 8.4$  years, stature:  $173.8 \pm 4.9$  cm, body mass:  $69.5 \pm 2.6$  kg and one female: 41 years, 168.0 cm, 57.5 kg), and two recreational exercisers (one female: 46 yrs, 177.0 cm, 78.3 kg and one male: 44 yrs, 188.0 cm, 94.7 kg). Subjects performed a submaximal running test that was followed by a graded test to

exhaustion under two conditions; without, and one hour after consuming, a Buzz bar in a randomised cross-over design. The submaximal test comprised 4 x 4 minute stages at increasing speeds (11, 12, 13, 14 km.hr<sup>-1</sup> and 12, 13, 14, 15 km.hr<sup>-1</sup> for female and male subjects, respectively). The graded test was performed at a constant speed (13 km.hr<sup>-1</sup> for females and 14 km.hr<sup>-1</sup> for males) with gradient increasing by 1% every minute until the subjects reached exhaustion. Oxygen uptake (VO<sub>2</sub>), blood glucose (Glu), blood lactate (La), heart rate (HR) and rating of perceived exertion (RPE) were determined at the end of each stage and at exhaustion. Time to exhaustion (TET) was recorded at the end of the graded test. Blood lactate (Lapeak) and blood glucose (Glupeak) were measured 5 min post-exercise. After consuming a Buzz bar, submaximal oxygen uptake at 13 km.hr<sup>-1</sup> (VO<sub>2</sub>-13; 37.86 ± 4.6 v 32.14 ± 6.09 ml.kg<sup>-1</sup>.min<sup>-1</sup>, P=0.004) and RPE at exhaustion were significantly lower (18 ± 1.49 v 16.8 ± 1.66, P=0.001) and TET was 10% longer (393.3 ± 125 s v 433.4 ± 110.9 s, P=0.01). Also, HLapeak (10.01 ± 3.44 mM v 12.07 ± 3.61, P=0.005) and Glupeak (4.87 ± 0.70 mM v 5.64 ± 0.66 mM, P=0.01) were significantly higher with the Buzz bar. There were no differences in HRpeak (175.4 ± 10.56 bpm v 176.4 ± 9.93 b.min<sup>-1</sup>, P=0.28) or VO<sub>2</sub>max (48.2 ± 8.8 v 48.7 ± 9.85 ml.kg<sup>-1</sup>.min<sup>-1</sup>, P=0.3). These results agree with those of previous studies that have used other carbohydrate meals one hour before exercise (Thomas et al., 1991; Stevenson et al., 2005). The 10% longer TET in this study compares favourably with that stated by Kirwan et al (1998). Furthermore, these findings show that the Buzz bar is effective in maintaining carbohydrate supply during progressive intensity exercise while it has the benefit of being a healthy, additive free alternative to other commercial bars. Even though its relative effectiveness compared to such supplements is yet to be investigated.

## THE EFFECT OF CARBOHYDRATE AND EXERCISE ON POSTPRANDIAL LIPID METABOLISM RELATED GENE EXPRESSION

WU, C.1, TSENG, M.2, YANG, T.2, CHANG, C.2

1: NATIONAL CHUNG HSING UNIVERSITY; 2: NATIONAL TAIWAN COLLEGE OF PHYSICAL EDUCATION

**Introduction** Postprandial lipemia may attenuate by exercise, subsequently, to reduce the risk of cardiovascular diseases. The underlying mechanism of lipid metabolism in the liver is not fully elucidated. Peripheral blood mononuclear cells (PBMCs) gene expression has been suggested to represent lipid metabolism in the liver. Therefore, the purpose of this study was to investigate the effect of carbohydrate and exercise on lipid metabolism related gene expression after high fat meal. **Methods** Eight healthy, active male subjects completed 4 experimental trials in a randomized order and cross-over design. After overnight fast, subjects either ingested 75 g fructose (F) or 75 g glucose (G) and rest or exercise at 60% VO<sub>2</sub>max for 1 hour (F+EX, G+EX) before an oral fat tolerance test. Blood samples were collected during 6 hour postprandial period. Peripheral blood mononuclear cells (PBMCs) were harvested to obtain RNA to determine ApoA-I, Apo B, LDL-receptor (LDLR), VLDL-receptor (VLDLR) and HMGCoA reductase (HMGCR) mRNA expression using real-time PCR technique. **Results** The results showed that F and F+EX induced higher plasma ApoA-I and lower plasma total cholesterol and LDL-C than G and G+EX. There were no significant differences in ApoA-I, Apo B, LDLR, HMGCR, VLDLR gene expression between trials. However, there was a trend that ingesting F trial indicated a lower VLDLR gene expression. The current data suggested that ingestion of different carbohydrates and exercise before a high fat meal did not influence postprandial lipid metabolism related gene expression. **References** Pocathikorn, A., Taylor, R., James, I., & Mamotte, C. ## EFFECT OF WHEY PROTEIN ISOLATE ADDITION TO A CARBOHYDRATE-ELECTROLYTE REHYDRATION SOLUTION INGESTED AFTER EXERCISE IN THE HEAT

JAMES, L.J., GINGELL, B., EVANS, G.H.

NOTTINGHAM TRENT UNIVERSITY

It is commonly reported that individuals finish an exercise session in a hypohydrated state. This means effective rehydration after exercise is an important athletic consideration, especially in situations where two bouts of exercise are undertaken in close proximity. Seifert et al (2006) reported that retention of a 60 g/l carbohydrate, 15 g/l protein drink was greater than of a 60 g/l carbohydrate drink, but failure to match drinks in terms of energy density makes it difficult to determine whether the protein or the increased energy density accounted for the difference in drink retention. The purpose of the present study was to determine the effects of energy matched carbohydrate and carbohydrate-whey protein isolate solutions on rehydration after exercise-induced dehydration. Twelve apparently healthy males (Mean (SD)) 21 (1) y, height 1.82±0.08 m, body mass 82.71 (10.31) kg) lost 1.9 (0.1) % of their initial body mass via intermittent exercise in a hot environment (35 (0.1) °C, 50.9 (2.1) % relative humidity). Subjects then rehydrated with 150% of their body mass loss over 1 h, with either a 65 g/l carbohydrate (35 g/l glucose, 30 g/l maltodextrin) solution (C) or a 50 g/l carbohydrate (35 g/l glucose, 15 g/l maltodextrin), 15 g/l whey protein isolate solution (CP), matched for energy density, as well as sodium (~20 mmol/l) and potassium (~5 mmol/l) concentration. Urine samples were collected before and after exercise and for 4 hours after rehydration. Subjects' pre-trial body mass (P = 0.080) and urine osmolality (P = 0.355) were not different between trials, suggesting they started each trial in a similar euhydrated state. Total cumulative urine output after rehydration was not different between trials (1173 (481) ml (C) and 1180 (330) ml (CP)) (P = 0.964), whilst drink retention during the study was also not different between trials (50 (18) % (C) and 49 (13) % (CP)) (P = 0.876). At the end of the study, net fluid balance was significantly negative compared to baseline for C (-432 (436) ml (P = 0.034)) and CP (-432 (302) ml (P = 0.003)). Whilst urine osmolality changed over time (P < 0.001), there was no difference between trials (P = 0.803). These results suggest that when matched for energy density and electrolyte concentration, a carbohydrate-whey protein isolate solution neither enhances nor inhibits rehydration in comparison to a carbohydrate solution. These findings indicate that in situations where the ingestion of protein after exercise might infer some benefit for post-exercise recovery, whey protein could be added to rehydration solutions without interfering with the rehydration process. Seifert J, Harmon J and DeClercq P (2006) Protein added to a sports drink improves fluid retention. *International Journal of Sports Nutrition and Exercise Metabolism* 16, 420-429. Seifert J, Harmon J and DeClercq P (2006) Protein added to a sports drink improves fluid retention. *International Journal of Sports Nutrition and Exercise Metabolism* 16, 420-429.

## COMBINED EFFECTS OF AEROBIC EXERCISE AND HIGH CARBOHYDRATE MEAL ON PLASMA ACYLATED GHRELIN AND LEVELS OF HUNGER

OLIVEIRA, A.R.1, BECKER, G.F.1, MACEDO, R.1, CUNHA, G.S.1, MARTINS, J.1, LAITANO, O.2

1: UFRGS (PORTO ALEGRE, BRAZIL), 2: UNIVASF (PETROLINA, BRAZIL)

**Introduction:** Ghrelin is an orexigenic hormone that is involved in appetite control and energy homeostasis (Cummings, 2006). Acylation of ghrelin is essential for appetite regulation (van der Lely et al., 2004). Food intake and physical exercise affect energy homeostasis. Although many studies have separately examined the effect of short-term exercise and meal consumption on appetite (Burns et al.,

2006; Tannous dit El Khoury et al., 2006), the potential interactive effect of both has yet to be investigated. The present study examined the effect of an aerobic exercise bout associated with a high-carbohydrate (CHO) meal on plasma acylated ghrelin levels and hunger sensation. Methods: Eight healthy males signed an informed consent for participation in the study and performed two experimental trials, exercise (ET) and control (CT). In ET, participants consumed a high-CHO meal and after resting for 2 h, performed a 60-minutes cycling exercise at 10% below the second ventilatory threshold (~70% of maximal oxygen uptake). After exercise, they rested for an additional hour. In the CT, after consuming the high-CHO meal, participants remained at rest throughout the whole period. Blood samples were taken over the trials to determine the levels of acylated ghrelin, glucose, insulin, total cholesterol (TC) and triglycerides (TG). The hunger sensation was assessed by using a visual scale. This study was approved by the University Ethics Committee. Results: There was suppression of hunger after eating the meal in ET and CT ( $p=0.028$  and  $p=0.011$ ). Hunger increase in CT during the exercise session ( $p=0.017$ ) and remained suppressed in the ET. Acylated ghrelin levels were suppressed in ET when compared to CT at the end of exercise bout ( $24.4 \pm 8.1$  vs.  $55.8 \pm 33.3$  pg/dl, respectively,  $p=0.017$ ). Inverse correlations between acylated ghrelin levels and insulin, TC and TG levels at different time points were observed. Conclusion: This study suggests that one bout of aerobic exercise maintain the meal-induced suppression of hunger and the reduced levels of acylated ghrelin right after the exercise may be involved in the mechanism underlying the appetite regulation. Additional factors such as insulin, TC and TG concentrations may be also involved in this phenomenon. Mensure Aydin\*, Nermin Sari\*, Bergun Meric Bingul\*, Cigdem Bulgan\*\* \*Kocaeli University, School of Physical Education and Sport \*\* Haliç University, School of Physical Education and Sport The aim of this study was to investigate the effects of recreation activities on life quality of old age people who lives in local nursing house in Kocaeli, Turkey. 17 old people mean age  $67 \pm 3,4$ , was participated to the study who lives in Kocaeli Local Nursery House. Recreational activities were organized for 3 days per week and 20 weeks in total. All participants were applied recreation activities which were included finger exercises with stress ball, ventilation exercises, walking exercises on the line, simple folk dance activities, stretching exercises with elastic bandage and stretching exercises on chair, weight exercises with plastic water bottles, different figure activities with play dough etc. Whoool Bref (TR) Life Quality Scale was applied participants before and after the activities. All statistical analyses were done by SPSS 16.0 programme. Wilcoxon statistical test were applied to compare of the pretest and posttest. As a result of the study there was significant difference in psychological parameters ( $p < 0,05$ ). In conclusion, it can be say that recreational activities effect positively of people mind health and increase the life quality. Recreational activities might be quite important especially for old age people to support their psychological health.

#### INTERNATIONAL REPORT OF MASTERS ABILITY SURVEY < IRMAS >: THE EXPERIENCE OF THE WORLD MASTERS ORIENTEERING CHAMPIONSHIPS 2010 IN NEUCHATEL < SWITZERLAND >

SCHRAGO, G.

DALER HOSPITAL

Purpose: This medical study was performed during the World Masters Orienteering Championships in 2010 in Neuchatel ( Switzerland ). The objective was to make a good evaluation of the health of the international athletes according to the age, and therefore to test the efficiency of the new quick cardiovascular screening methods in current practice. Methods: The official medical informations were on the organization homepage: [www.wmoc2010.org](http://www.wmoc2010.org), and on this of the survey: [www.irmas.ch](http://www.irmas.ch) in 5 languages ( english, german, italian, french and russian ). In the clinical part, this parameters were controlled at the event center: heart rate, blood pressure, oxygen percentage in blood, intima media thickness ( IMT ). This material was used: for the heart rate and the blood pressure, an automatic system of the firm OMRON; to measure the oxygen, an ONYX pulsoxymeter; for the IMT, a portable ESAOTE My Lab 25 with a multi-frequency linear transducer ( 10-15 Mhz ). In the following monthes, 3 mailing ( with a link to a questionnaire of 40 epidemiological questions on the IRMAS homepage ) were sendes to the 2200 mails addresses in the database of the event organization. Results: In the clinical part, 201 participants, 35 to 83 years old ( mean age: 57 ), can be included: 83 women and 118 men. Mean heart rate at rest: 65 ( + 12 ) pro minute. Mean systolic blood pressure ( sitting ): 147 mmHg ( + 22 ). Mean diastolic blood pressure ( sitting ): 92 mmHg ( + 14 ). Mean oxygen percentage: 97% ( + 1,5 ). Mean IMT: 625 um ( + 146 ). 30 participants ( 15% ) had atheromatosis in the supraaortic vessels: 26 ( 13% ) < 25% stenosis, and 4 ( 2% ) with 25 to 50% stenosis. In the epidemiological part, we've received 578 valid questionnaires = a participation rate of 26,3% ( 28,5% women and 71,5% men ). Only 70 participants ( 12,1% ) have no history of trauma, and 196 ( 34% ) no illness history. 49 runners ( 8,5% ) have a past history of cardiovascular disease, and 22 ( 3,8% ) a cancer. Less than 1% were active smokers. The training level was good: one or more times sport a week for 94,8% of the participants. Conclusions: the regression analyse of the clinical data are according to the past studies for the systolic and diastolic blood pressure values 1. With the new portable sonography and softwares like for the IMT measure 2, it's possible to make a good cardiovascular screening in a few minutes ( mean time 10 minutes... ), out of the hospital, with low costs. The participants were good trained, and more fit as a standard reference population. 1) Data from prospective studies collaboration, Lancet 2002; 360: 1903. 2) Carotid Plaque Area and Intima-Media Thickness in Prediction of First-Ever Ischemic Stroke: A 10-Year Follow-up of 6584 Men and Women: The Tromso Study. ## THE RELATIONSHIP BETWEEN PHYSICAL FITNESS TEST AND QUESTIONNAIRE RELATED PHYSICAL EDUCATION IN UNIVERSITY STUDENTS

KAZUHIKO, T., TSUTOMU, S., HIROSHI, H., HIDEKATSU, T.

HOKUSEI GAKUEN UNIVERSITY

**Introduction** For human beings, a healthy and active life is the most important. The goal of the physical education is to provide appropriate exercise and knowledge for students. However, in our university, the physical fitness level is decreasing after 1985, year by year. The purpose of this study is to clarify the relationship between physical fitness level and factors related physical activity or health in our university students. **Method** The physical fitness test (8 items) and self-description questionnaire (1. Likes and dislikes of physical education class, 2. Health status, 3. Fitness level, 4. Body type, 5. Fitness history (Extracurricular physical activity) in Junior HS and High school) were conducted annually in the period of 2003 to 2009. The physical fitness test was developed by the Ministry of Education Japan. The subjects (n=3438) were 18-years-old students enrolled at Hokusei Gakuen University. **Results and Discussion** Approximately two-thirds of the students liked physical education class (Male 67%, Female 58%). A significant association was found between Likes/Dislike of physical education class and total score of physical fitness test, in each gender. There was a difference of total score between Likes and Dislikes (Male 4.3 point, Female 3.6 point,  $p<0.01$ ). It is important that students who dislike physical education have an interest in physical activity. In addition, fitness history related to total score significantly. The extracurricular physical activity in Junior HS and High school improved total point of physical fitness test (Male 3.0 point, Female 2.8 point,  $p<0.01$ ). Longer in extracurricular physical activity, total score of physical fitness was higher. In university education, it is important to increase physical activity for students who lack experience of physical activity.

## FACTORS ASSOCIATED WITH PHYSICAL ACTIVITY IN GERMAN ELDERLY MEN AND WOMEN: A CROSS-SECTIONAL STUDY

MOSCHNY, A.1, PLATEN, P.1, KLAABEN-MIELKE, R.2, TRAMPISCH, U.1, HINRICHS, T.1

1: UNIVERSITY OF BOCHUM, 2: UNIVERSITY OF BOCHUM

**Background** Data on physical activity in German elderly people are scarce. The aim was to analyse physical activity patterns and factors associated with physical activity in different domains, i.e. sporting activities (SA) and domestic activities (DA), in German elderly men and women. **Methods** Within the 7-year follow-up telephone interviews of the getABI cohort (community-dwelling primary health care patients in Germany), participants were surveyed on their everyday physical activity patterns using the PRISCUS-PAQ. Time per week (hh:mm) spent in SA and DA (heavy housework, gardening) was analysed for men and women. Logistic regression analyses were done to assess the odds of participating in SA and DA for at least 2.5 hours/week (hrs/wk) in association with socio-demographic variables, cardiovascular risk factors, walking ability, falls, pain, chronic conditions, number of medications, and season. **Results** A total of 1609 primary health care patients (51.6% women) with a median age of 77 (range 72-93) years were included into the analyses. Men engaged more in SA than women (median: 01:45 vs. 01:10), whereas women did more DA per week than men (median: 04:00 vs. 03:00). The need of a walking aid consistently lowered the odds of being active in both activity domains and sexes. SA: Male migrants were more frequently active for at least 2.5 hrs/wk. Women reporting pain had reduced odds, those living alone increased odds of performing SA. DA: Being interviewed in spring/summer increased the chance to do at least 2.5 hrs/wk, higher education lowered the chance to reach the amount of 2.5 hrs/wk in this domain, both in men and women. In both sexes, selective associations were found between several chronic diseases and sporting or domestic activities. **Discussion** This exploratory study revealed gender-related differences in physical activity patterns. Several factors emerged to be associated with physical activity in either or both activity domains, in men and/or women. Further investigation of physical activity patterns as well as the multifaceted reasons for participation in diverse physical activities is needed to deduce sound target group-specific physical activity intervention and promotion strategies. The study was conducted within the research cooperation PRISCUS and funded by the German Federal Ministry of Education and Research (01ET0720).

## DANCE AEROBIC VERSUS PILATES INTERVENTIONS: CHANGES IN BODY COMPOSITION AND SPINE MOBILITY IN HEALTHY ADULT WOMEN

GARCÍA-PASTOR, T., LAGUNA-NIETO, M., AZNAR-LAÍN, S.

CAMILO JOSE CELA UNIVERSITY

**Introduction:** Pilates is an exercise approach developed in the early 1900s that is based on Eastern and Western theories (Keays y cols., 2008). While anecdotal evidence suggest that as the PM increases muscle flexibility and becomes your body firmer and sleeker (Gallagher and Kryzanowska, 1999), limited experimental research exists. The aim of the study was to evaluate changes in body composition and spine mobility after 20 weeks of PM or aerobic dance intervention (2 hours/week) between three groups: PM practitioners (PMg), aerobic dance practitioners (Ag) and non exercisers (NEg). **Methods:** Total sample comprised 52 healthy adult women; ages between 29 and 59 years old ( $42.23\pm7.17$  years). The sample was divided into three groups: PMg(n=16), age ( $43.75\pm5.51$ ); Ag (n=18), age ( $42.71\pm6.9$ ) and NEg (n=22); age ( $40.94\pm8.7$ ). Body composition measures were body weight, height and body fat measured from 6 skin-fold thicknesses. To asses lumbar flexion and extension we used the Modified Schober Test. PMg and Ag participated in a 20 weeks program consisting of PM and Aerobic Dance group classes (2 hours/week) respectively, while NEg did not engaged in any regular physical activity. Analyses were conducted using SPSS (version15.0). One-way analysis of variance was used to examine differences in body composition and spine mobility across groups followed by post-hoc contrasts. The level of statistical significance was set at  $p<0.05$ . **Results:** After exercise programs there were significant differences among the three groups in body weight ( $F(2,49)=4.1$   $p<0.05$ ), the sum of skinfold thicknesses ( $F(2,48)=4.59$   $p<0.05$ ), body fat % ( $F(2,48)=6.37$   $p<0.05$ ), lumbar extension mobility ( $F(2,48)=8.92$   $p<0.05$ ) and spinal flexion mobility ( $F(2,49)=3.99$   $p<0.05$ ). Post-hoc analyses indicated that Ag scored higher vs NEg in the sum of skinfold thicknesses in 6 sites ( $p=.01$ ) and percentage of body fat ( $p=0.004$ ). PMg scored higher vs NEg in body weight ( $p=0.04$ ), lumbar extension mobility ( $p=0.001$ ) and spinal flexion mobility ( $p=0.026$ ). **Conclusions:** A 20 weeks PM program (2 days/week) improves body weight and, spinal flexion and extension mobility, versus an aerobic dance program in a sample of healthy adults from Boadilla del Monte, Madrid, Spain. **Bibliography:** Keays, K. ## EFFECTS OF A MULTIDISCIPLINARY INTERVENTION ON THE MOTOR PHYSICAL FITNESS OF HEALTH CARE PROFESSIONALS.

ZINZEN, E.1, KOS, D.2, DE CLERCK, M.2, HEYRMAN, A.2, NIJS, J.1

\*Vrije Universiteit Brussel; Pleinlaan 2; 1050 Brussel; \*\*Artesis University College Antwerp, Van Aertseleerstraat 31, 2170 Antwerpen

Evert.Zinzen@vub.ac.be Introduction. Low physical fitness is assumed to be one of the major factors contributing to an increased incidence of cardiovascular disease, diabetes mellitus, obesitas, musculoskeletal problems, .... Burton et al. (2004) indicate in their European Guidelines for Prevention of Low Back Pain (LBP) that increasing physical fitness level is the most effective action in primary prevention for LBP. The nursing population is very sensitive for LBP. Purpose. The first aim of this study was to investigate the immediate effects of a multidisciplinary intervention in a hospital setting on the physical fitness of health care personnel. The second aim was to investigate if these effects remain six months after the intervention. Methodology. Sixty health care professionals (50 F and 10 M) volunteered to participate to this study. The Eurofit test battery (EUT) was taken before the intervention, just after and after a period of 6 months. The EUT consists out of 8 tests: Flamingo Balance (FLB), Plate tapping (PLT), Sit and Reach (SAR), Standing Broad Jump (SBJ), Sit Up (SUP), Bent Arm Hang (BAH), Handgrip (HGR) and a Shuttle Run (SHR). BMI and waist circumference were added. The 5 month intervention consisted out of convincing the hospital management, improving general health aspects, an ergonomic approach and working on the psycho-social level according to Zinzen et al. (2000). One-way ANOVA with the Scheffé post hoc test was used ( $p < .05$ ). Results. Most participants experienced the EUT test as a rather heavy physical performance resulting in a reduced participating level for the post tests: 29 (24F and 5M) right after and 21 (16F and 5M) after six months. All datasets were overall normally distributed. For the total group only the FLB ( $25.5 \pm 27.3 > 12.9 \pm 4.8 > 11.4 \pm 4.8$ ) and PLT ( $12.07 \pm 1.9 > 10.7 \pm 1.5 > 10.8 \pm 1.7$ ) improved significantly after the intervention and stayed on the same level after six months. In the male group no significant differences could be noted between test sessions whilst in the female group FLB ( $25.9 \pm 27.6 > 13.3 \pm 4.8 > 10.9 \pm 4.7$ ), PLT ( $12.2 \pm 2.0 > 10.9 \pm 1.5 > 10.9$ ) and HGR ( $340.8 \pm 65.7 > 395.4 \pm 61.9 > 390.8 \pm 74.4$ ) significantly improved after the intervention and stayed better. The SBJ in the females improved ( $127.7 \pm 27.2 > 143.5 \pm 25.5 > 142.9 \pm 20.0$ ) although only significant immediately after the intervention. Conclusions. Improvements on equilibrium speed of limb movement, static arm strength and explosive leg power could be noted in the female nurses. The small male sample size could be the reason for not finding any improvements.

## EFFECT OF A LIFESTYLE INTERVENTION ON ADIPOSITY AND FITNESS IN HIGH-RISK SUBGROUPS OF PRESCHOOLERS: A CLUSTER-RANDOMIZED TRIAL

BÜRGI, F., NIEDERER, I., EBENEGER, V., SCHINDLER, C., BODENMANN, P., MARQUES-VIDAL, P., KRIEMLER, S., PUDER, P.

UNIVERSITY OF BASEL, UNIVERSITY OF LAUSANNE

Background: Children with migration background and from families of low educational level (EL) are considered high risk groups for the development of obesity and low fitness and interventions in these populations seem to be less effective. We therefore investigated, whether a preschool-based lifestyle intervention was equally effective in migrant compared to nonmigrant children and in children from low EL families compared to those from families of middle/high EL. Methods: Forty preschool classes were randomly selected and randomized 1:1 into an intervention and a control arm after stratification for language region (French vs. German part of Switzerland). The intervention included a physical activity (PA) program, lessons on eating habits, media use and sleep, and adaptation of the built environment using approaches to target a multiethnic population. Primary outcomes were BMI and aerobic fitness; secondary outcomes were percent body fat, waist circumference and motor agility. Interactions with migrant status and parental EL were tested and stratified analyses performed. Results: In the total population the intervention had no effect on BMI, but was beneficial for total and central body fat and for both physical fitness measures (aerobic fitness and agility). There was a small tendency for a decreased intervention effect on aerobic fitness in children with migrant background and in children with low parental EL ( $p$  for interaction = 0.06 and 0.09). However, the intervention effects on all adiposity measures and on motor agility were not modified by migration background or EL ( $p$  for interaction 0.2 and 0.9), though intervention effect sizes were smaller in children of low EL families. Conclusion: Despite smaller effect sizes for the low EL children, this culturally targeted intervention was equally effective in preschoolers of migrant background and low EL children compared to their counterparts. It therefore might represent a promising option to reduce adiposity and increase fitness for these children.

## AWARENESS OF PHYSICAL ACTIVITY RECOMMENDATIONS FOR HEALTH IMPROVEMENT AMONG PORTUGUESE ADULTS

VIEIRA, S.1, ESTEVES, D.1,2, BRÁS, R.1,2, PINHEIRO, P.1,3, RODRIGUES, R.1,3, O'HARA, K.1,2

1UBI (COVILHÃ, PORTUGAL), 2CIDESD (PORTUGAL), 3NECE (COVILHÃ, PORTUGAL)

Introduction Regular moderate physical activity (PA) has an important influence on health and well-being, but is not clear if adult population knows the adequate PA characteristics for health improvement (Bennett et al., 2009). ACSM recommends a minimum of 30 min of moderate-intensity PA on 5 days/week to promote and maintain health (Haskell et al., 2007). The aim of this study is to examine whether knowledge of ACSM recommendations is accurate among Portuguese adult population and if it varies with PA information source. Methods The study included a randomly recruited sample of 879 subjects (53% M; 47% F),  $42.3 \pm 19.4$  y. A survey was designed to (1) evaluate knowledge on PA characteristics for health benefits; (2) evaluate knowledge on adequate exercise heart rate; (3) relate PA knowledge and PA level (assessed by IPAQ) and (4) relate PA knowledge and PA information source. Results Evaluation on adequate PA characteristics found 74.5% of wrong answers. Evaluation of knowledge on adequate exercise heart rate found 82.1% wrong answers. For information sources friends/family; teachers, Internet and sport professionals there were statistically significant differences between the groups with adequate and low PA, meaning that those information sources positively influence an active lifestyle. Teachers, Internet and sport professionals are the only information sources that report a positive effect on % of right answers, regarding adequate PA characteristics. Discussion Despite efforts to promote PA and widespread knowledge on ACSM recommendations, few (about a quarter) Portuguese adults can accurately identify adequate PA characteristics for health improvement. Similar results were found by Bennet et al. (2009) among USA adults. These findings highlight the limited ability to enhance knowledge from traditional PA informative campaigns (Hornik, 2002, Pinheiro et al., 2011) and the need for more effective campaigns to widespread accurate information, using new technologies coordinated with traditional media. ##### THE RELATIONSHIP BETWEEN THE PSYCHOLOGICAL EMPOWERMENT FACTORS AND ORGANIZATIONAL ENTREPRENEURSHIP IN PHYSICAL EDUCATION TEACHERS

HEMMATI, J.

AZAD UNIVERSITY

Hemmati, J.1 Eslami, S.2 1: IAU (Islamic Azad University, Khoramabad Branch, Iran), 2: PNU (Delfan/Iran) Introduction Physical education teachers in university with abilities such as innovation, creativity and empowerment can help human resource and guide them during the education in universities. They could educate aware human resource and prepare them to accommodate with all of the changes that exist in around them. Therefore the aim of this study was to investigate the relationship between the psychological empowerment factors such as meaningfulness, Competency, self determining, impact, Trust and entrepreneurship in teachers of physical education in university. Methods Method in our research was descriptive- correlational. Fifty three of physical education teachers were selected from participant in scientific development volleyball congress. Spritzer and Samad Aghaee Questionnaires, were used to gather data related to empowerment factors and organizational entrepreneurship respectively. We used statistical test of Pierson to investigate the relationship between psychological empowerment factor and organizational entrepreneurship. Results Test of emphasis showed that four of psychological empowerment factors including: Meaningfulness, Competency, Self determining and impact did not directly deal with organizational entrepreneurship. But there was a significant relation between trust factor and organizational entrepreneurship. Discussion Findings in our research showed that in universities is not paid attention to some of teachers psychological empowerment factors such as; meaningfulness and mental standards, Competency and attention to skills and abilities of teachers, Self determining and independence and liberty of teachers activates, Impact and teacher effectiveness too (Laxchinger & et al., 2005). but the result of trust factor shown that assurance to teachers in university lead to empowerment of organizational entrepreneurship in sport faculties (Skinner et al., 2003). Some of the factors that lead to different this study with others includes; sample and statistical universe, education, social situation and anticipations of organizational environment (Ozaralli., 2003 & Siegall et al., 2000). ##### STUDY ON NEUROPHYSIOLOGICAL AND PHYSO-PEDAGOGICAL ASPECTS OF REGULATION DOCUMENTS IN ITALIAN PRIMARY SCHOOL

RAIOLA, G.

UNIVERSITY OF SALERNO

Introduction In recent years Italian primary school, as called in the past time elementary school and the pupils go between 5 years old to 10, has been updated the ministerial documents relating to the educational contents and activities. At the same time, recent discoveries about the neurophysiology of the brain changed the scientific bases on which are based psychological and pedagogic paradigms on educational theories. These theories are the basis on motor learning according to motor control system such as closed loop system (Adams 1975), open loop system (Schmidt 1985) and motor imagery (Rizzolatti 2006, Iacoboni 2008). The aim is to identify, into the regulation documents regarding the educational activity, aspects of psychology and pedagogy in the field of body and movement Method Research is integrated by two approaches: Theoretical and argumentative one on scientific paradigms regarding the motor control system theory and the related motor learning in the early years of life and, the second one, historical and documentary approach on regulation documents relating to the contents and the teaching activities Result It does not carry out any aspects of education and didactics that can be connected to psychological and pedagogic aspects according to the new scientific and neurological theories. All regulation documents do not provide any reference to recent discoveries related to the theory of movement correlating the motor learning Conclusion It may be useful to update the regulation documents. It needs to deep properly the study and then to deliver the results to the governmental experts for the necessary updates to fill up the vacuum of the contents, didactics and teaching method for the particular field of motor control and learning. Furthermore, the movement field must help the educational science in an holistic vision of development References Latash M., (2008) Neurophysiological Basis of Movement, Human Kinetics, Champaign IL USA Schmidt, R., A., Wrisberg, G., A., (2008) Motor Learning and Performance, Human Kinetics, Champaign IL, USA Iacoboni M., (2008) Mirroring People. ## A RESEARCH ON THE PROBLEM-SOLVING AND AUTOMATIC –THOUGHTS SKILLS OF THE STUDENTS STUDYING AT PHYSICAL EDUCATION AND SPORTS ACADEMY

TEKIN, M.

KARAMANOĞLU MEHMETBEY UNIVERSITY

A RESEARCH ON THE PROBLEM-SOLVING AND AUTOMATIC –THOUGHTS SKILLS OF THE STUDENTS STUDYING AT PHYSICAL EDUCATION AND SPORTS ACADEMY Tekin, M. 1, Şahan, H. 2, Yıldız, M.3, Güllü, M.4 Devecioğlu, S.5 1 Karamanoğlu Mehmetbey University College of Physical Education and Sports, Karaman, Turkey 2 Karamanoğlu Mehmetbey University College of Physical Education and Sports, Karaman, Turkey 3 Karamanoğlu Mehmetbey University College of Physical Education and Sports, Karaman, Turkey 4 İnönü University College of Physical Education and Sports, Malatya, Turkey 5 Firat University College of Physical Education and Sports, Elazığ, Turkey Introduction It is important that negative automatic thoughts and problem solving skills of the students studying at physical education and sports academy be examined out of their tasks such as being a good model in future, educating a qualified student and developing creativity. For this reason in this research; problem solving and automatic thoughts skills of the students studying at physical education and sports academy are aimed to be investigated. Method Research stuff is consisted of 196 male and 146 female (age=19,3713 + 1,6968) and totally 342 students studying at Selçuk University, İnönü University, Gazi University and Karamanoğlu Mehmetbey University Physical Education and Sports Academy. To reach the aim of this research; Problem-solving Inventory (PSI) developed by P.P. Heppner and C.H. Petersen (1982) and adjusted to Turkish by Savaşır and Şahin (1997) and Automatic Thoughts Questionnaire developed by Hollon and Kendall (1980) and adjusted to Turkish by Şahin and Şahin (1992) are used. Results As the result of this study; Moreover; it is discovered that there is an effective explanatory among thinking approach, avoidance approach, evaluator approach, self-confident approach and planned approach from sub-dimensions of the automatic thoughts skills and problem-solving skills ( $p < 0.05$ ). Discussion All these results show that students studying at physical education and sports academy, who are representing only a part of university students, have some problems in terms of problem solving skills and automatic thoughts and it is thought that some part of these problems arise from university students' conditions in which they live. (Ingram and Wisnicki, 1988) The findings in this study were parallel with the current study. References Heppner P.P., Petersen, C.H. (1982). ## SURVEY OF THE OPINIONS OF LIFE ORIENTATION SUBJECT ADVISORS ON THE RE-IMPLEMENTATION OF PHYSICAL EDUCATION IN SOUTH AFRICAN SCHOOLS

SPAMER, E., VAN DER MERWE, N.

NORTH-WEST UNIVERSITY (POTCHEFSTROOM CAMPUS)

Introduction Prior to 1994 Physical Education was a compulsory, non-examinable school subject in all South African schools. After the first democratic, non-racial election in South Africa in 1994, Physical Education was phased out as a lone standing, separate school subject according to the new South African schools act of 1996 (DoE, 2000). Physical Education was included as one of the five outcomes of the Learning Area Life Orientation and implemented gradually from Grade R to Grade 11 to be completed in 2008 when the outcome was presented in Grade 12 for the first time (Pote, 2008). Methods The aim of this research was the evaluation of the re-implementation of Physical Education in South African schools. The quantitative research design supported by a limited qualitative data set included six phases. In 2008 during Phase 3 of this study, 277 Life Orientation subject advisors from all nine provinces in South Africa completed a questionnaire directly after completion of a Physical Education training workshop. After two years, in 2010, these subject advisors completed a follow-up questionnaire on the re-implementation of Physical Education in schools. Results Irrespective of the fact that almost 50% of these subject advisors have no qualification in Physical Education, they are very positive about the presentation of the subject. Additional challenges experienced by the subject advisors are meagre or unqualified Life Orientation teachers in Physical Education (78%), no or inadequate facilities, apparatus (60%) and support (39%) for the presentation of the subject as well as very large numbers of learners in classes (70%). Discussion The reinstatement of Physical Education within Life Orientation in the South African school curriculum brings several challenges for Life Orientation subject advisors, especially in the light of insufficient qualifications and experience to advise teachers who teach Physical Education. This as well as the challenges with facilities, apparatus and support for the subject result in the non-presentation of Physical Education in several South African schools. Such an unwanted situation can hold serious consequences for the health situation, economic development as well as national and international sporting achievements for a potential upcoming, developing country as South Africa (Van der Merwe, 2010). References POTE, N. 2008. Physical Education as outcome of Life Orientation. Pretoria. (Personal conversation with researcher, 21 Sep. 2008.) SOUTH AFRICA. Department of Education. 2000. Evaluation of the re-implementation of Physical Education in South African Schools Potchefstroom: North-West University, Potchefstroom Campus. (Thesis – Ph.D.)

## TRAINING OF THE PERSONAL TRAINERS THAT WORK IN REGION OF VALENCIA

CAMPOS, A.1, PABLOS, C.2, PABLOS, A.3, GONZÁLEZ, M.D.4

1: TECHNICAL UNIVERSITY OF MADRID (MADRID, SPAIN), 2: UNIVERSITY OF VALENCIA (VALENCIA, SPAIN), 3: UNIVERSITY CATHOLIC OF VALENCIA (VALENCIA, SPAIN), 4: UNIVERSITY OF ALCALÁ (ALCALÁ DE HENARES, SPAIN)

Introduction The personal trainer is a qualified professional that teach and train customers with safety and suitable exercises. The objective is to increase the physical condition and the health of his customers (Roberts, 1996). Forteza, Comellas y López (2004) add that the personal trainer is a professional dedicated to the individualized training for people that need to improve their physical condition in a general or specific way to achieve objectives from the health to the high performance. It is necessary that this personal trainer has an initial and continuous education adequate to carry out the training with efficiency and adequately. Methods We have used a quantitative methodology of descriptive cut. The procedures applied were the proper procedures of the survey. We have done individual interviews to 600 persons who work as personal trainers in Region of Valencia (Spain). Results When we analyze the initial education of the personal trainers polled we observe that 57'3% of them do not have any qualification in physical activity. 14'8% have a physical activity degree, 13'1% are trainers, 6'6% are physical education teachers of primary school, 6'6% have technical sport qualification (TAFAD) and 1'6% have

technical sport qualification in outdoor activities. Related with their continuous education, 65'6% of these personal trainers have done courses or postgraduate courses and 24'6% have attended to conferences. Discussion Most of personal trainers polled do not have any qualification in physical activity. Furthermore, to this percentage we have to add the people with sport qualifications without enough knowledges to develop this tasks. This reality shows the small percentage of personal trainers qualified with an initial education suitable to carry out this activity. These trainers cannot guarantee the quality and efficient development of the personal trainings (Camy, Chantelat y Le Roux, 1999; Campos, 2010). Related to the continuous education of the personal trainers, most of them have done courses or postgraduate courses (Campos, 2010). References Campos, A. (2010). ## **GENDER DIFFERENCES IN FUNDAMENTAL MOVEMENT SKILL DEVELOPMENT IN SIX-YEAR-OLD FLEMISH PRE-SCHOOL CHILDREN**

VANDAELE, B.

*FREE UNIVERSITY BRUSSELS (VUB)*

Gender differences in fundamental movement skill development in six-year-old Flemish pre-school children Vandaele, B (1,2), Cools, W (2), De Decker, S (1), De Martelaer Kristine (2) 1: Erasmus hogeschool Brussel, Departement of Teacher Training 2: Vrije Universiteit Brussel, Departement of Physical Education and Sports Training Introduction There is still no agreement on gender differences in movement skill performance of pre-school children. Some studies report no gender differences in FMS (locomotor tasks) at the age of six (Butterfeld, 2002), others only observe significant gender differences when explosive strength is the underlying ability of the task (Zurck, 2005). Methods Two hundred thirty six 6-year-old Flemish pre-school children (N=236) were individually assessed with the Motoriktest für Vier- bis Sechsjährige Kinder (MOT 4-6). Children's performances on 17 tasks were rated on a 3-point scale (0,1,2) and generated a Total Score (TS) of 34. Descriptive analyses were used to report frequencies and percentiles of scores. Results Mean TS was 20.78 (SD= 5.7), without significant gender differences. When comparing FMS profiles of boys and girls, different trends occurred. Boys outperformed girls in the object control skills throwing at a target (boys 68.1% and girls 35.7% score 1 or 2, U= 4218,5 p< 0.01, r= 3,63) and catching a ring (boys 78.3% and girls 57.1% score 1 or 2, U= 5014,0 p< 0.01, r= 3,33). In the locomotion skills 'jumping jacks' (girls 84.7% and boys 65.9% score 1 or 2, U= 4734,5 p<0.01, r= 3,43) and 'turning jump' (girls 87,8% and boys 83,3%, U= 5763,0 p<0.05, r= 3,11) girls outperformed boys. More subtle differences appeared for the 'jumping in a hoop and balancing on one leg' and 'side jump' for which girls performed better, and the 'transporting balls' and 'roll around the axis' in which boys had a higher proficiency. Discussion Significant gender differences in our study were in accordance with several other studies. Our results seemed to match the findings of other authors who demonstrate girls to be typically performing more successfully in balancing (Sigmundsen, 2003) and jumping tasks (except the height jump) and boys outshining in running and catching tasks (Hardy, 2009). ## **FUNDAMENTAL MOTOR SKILLS IN 11-12 YEARS-OLD BOYS AND GIRLS: A CROSS-SECTIONAL STUDY**

CASOLO, F., FRATTINI, G., MONDONI, M., VAGO, P.

*CATHOLIC UNIVERSITY, MILAN*

INTRODUCTION Fundamental Motor Skills (FMS) are common motor activities with specific observable patterns. Most skills in sports and movement activities are advanced versions of FMS. During the secondary schooling period, students should be taught physical education to further develop their basic motor skills such as throwing, catching and running, into more complex and specific sport and leisure activities. It is also evident from research findings that many children and adults do not regularly take part in physical activities that contribute to a healthy lifestyle. There are many reasons for this lack of physical activity, the most evident being the lack of exposure at an early age to physical skill development activities. From a motor development perspective, FMS are important as they play a primary role in young children's skills learning and motor development (Haywood & Getchell, 2009). METHODS In the year 1985 a test battery was submitted to 1160 (589 boys 561 girls) Italian students aged 11 and 12 (GR1). The same test battery was proposed to 1465 (772 boys 693 girls) same aged students in 1996 (GR2) and 1276 (644 boys 632 girls) students in 2010 (GR3). The data were collected through the scholastic system by submitting tests during physical education (PE) lessons after a 20 minutes warm-up. Test battery: Speed Running (m. 80), Endurance Running (m.1000), Long Jumping, High Jumping, Precision Throwing (Basket) and Power Throwing (one hand ball throwing of a 0,3 Kg. for girls and 0,4 Kg for boys), Rope Skipping and Pole-Climbing. RESULTS In the two periods 1985-1996 (P1) and 1996-2010 (P2) differences in the body mass, in height and BMI were found. Today boys and girls are notably taller and heavier. The increase of these two dimensions in children's morphology is predominant for the increase in body mass, as shown by the marked increase in BMI. All data were compared with the NCHS Growth Charts (NCHS 2000). In all tests a loss of ability in each group was found. Gaps were more evident in endurance and power abilities than in precision tasks. Regarding the sex category, these differences are more evident in the girls. Differences among the participants according to their age and birth date were analyzed with the Pearson's Chi-square test and statistical significance were confirmed by the O.R. (Odds Ratio) values. DISCUSSION FMS competence has been shown to influence children in many ways. Students who have achieved FMS competence have been found to successfully participate in a range of sports and movement activities and maintain involvement during childhood and adolescence. Regular involvement in sport and movement activities lead to gains in health-related physical fitness. FMS competence plays a fundamental role in preparing students for a healthy lifestyle.

## THE ASSESSMENT OF THE MOTOR SKILLS AS INDICATOR OF THE TEACHER'S TEACHING ABILITIES. PILOT STUDY OF A POSSIBLE COMPARISON BETWEEN THE ITALIAN AND THE INDIAN PRIMARY SCHOOL

DI TORE, S., GOMEZ PALOMA, F., SIBILIO, M.

UNIVERSITY OF SALERNO

The visual-motor integration represents a main condition in the learning processes and it is absolutely necessary to get the reading-writing ability. It supports as well the higher learning processes which are involved in the school experiences. Anyway, it isn't always considered important in the educational environments. Nowadays, the scientific literature seems to recognize the importance of the movement in the integration of different mental processes (Marsha W., Amundson S., 1994). With regard to this, Hannaford assumed that "every time we move in an organized manner, full brain activation and integration occurs, and the door to learning opens in a natural way" (Hannaford, C., 1995). The visual-motor answers can be considered as the first sensory integration of the growth and so they appear as one of the main goal that every educational system should pursue. The aim of this research is to carry out, investigate and monitor if the current school systems duly support the development of students' visual-motor abilities in the primary school. The method used scheduled the following phases: 1. Arrangement of an integrated plan between the school and the university to share the aims, the methods and the actions of the research. 2. Transfer of the needed knowledge to the teachers to give the VMI and VMI tests for the motor coordination. 3. Giving the VMI and VMI tests for the motor coordination to the students according to procedures described in the hand-book. 4. Assessment of the tests made. 5. Analysis and processing of the obtained data. The instrument used to carry out the research is the VMI test (K.E. Beery, 2000), scientifically effective, and its motor coordination sub-test. We got the data from 112 students of the Italian primary school and 51 students of the Indian primary school. The data show that the mean of the scores got from the Indian sample are significantly lower than the international mean. The data got from this sample have to be considered as an alarm bell which cannot be ignored. Due to the strong link of the VMI to the future school efficiency, the effects of the pathological situation described in this article risk to influence the future cultural level of the two Countries. ## THE TEEN RISK SCREEN: A MOVEMENT SKILL SCREENING CHECKLIST DESIGNED FOR TEACHERS

AFRICA, E.

STELLENBOSCH UNIVERSITY

The teen risk screen: A movement skill screening checklist designed for teachers Eileen K. Africa (Department of Sport Science, Stellenbosch University, Stellenbosch, RSA) Introduction Late childhood is not only marked by rapid physical changes, children also need to perform a repertoire of movement skills during their daily functioning (Sugden & Sugden, 1990). The importance of fundamental movement skills are often taken for granted, as it is seen as a normal part of human development (Cools et al., 2008). It is expected that these movement skills will be adequate to muddle through the school career with ease, however, some children struggle and are regarded as clumsy. This study therefore aims to provide an easy-administered screening checklist to determine children's fundamental movement skills in a school setting. Methods The study sample (N=133) consisted of 126 girls and seven classroom teachers from a selected school in the Stellenbosch region, Western Province, South Africa. The teachers were trained by the researcher's assistant to administer a 26-item movement skills screening checklist, while the children were performing physical activities. The checklist consisted of seven subscales, namely, posture and stability (axial movement); postural stability (dynamic movement); locomotor skills (single skills); locomotor skills (combinations); manipulative skills (sending away); manipulative skills (maintaining possession) and manipulative skills (gaining possession). The items underneath each subscale ranged from two to seven items. Results The results will be reported at the conference in July 2011. Discussion Fundamental movement skills are seen as building blocks for complex movement patterns. Children with better fundamental movement skills are more likely to engage in physical activity, since motor proficiency is inversely related with sedentary lifestyles (Wrotniak et al., 2006). It is thus important to understand fundamental movement skills to identify problems so that remedial intervention can be offered (Piek & Edwards, 1997; Brantner et al., 2009). There is a paucity of research studies in this area (Ward et al., 2010). Consequently, future quality research is vital using validated screening checklists in conjunction with validated movement skill assessment tools (Cliff et al., 2009). ## ARE ADDITIONAL 15 MINUTES A DAY SUFFICIENT TO PROMOTE FUNDAMENTAL MOTOR SKILLS IN PRE-SCHOOL CHILDREN IN A KINDERGARTEN-SETTING?

ZAHNER, L., ERNST, D., BAUMANN, A., SIEBENHAAR, N., DONATH, L., MUEHLBAUER, T.

INSTITUTE OF EXERCISE AND HEALTH SCIENCES, UNIVERSITY OF BASEL, SWITZERLAND; INSTITUTE OF SPORT SCIENCE, FRIEDRICH-SCHILLER-UNIVERSITY JENA, GERMANY

ARE ADDITIONAL 15 MINUTES A DAY SUFFICIENT TO PROMOTE FUNDAMENTAL MOTOR SKILLS IN PRE-SCHOOL CHILDREN IN A KINDERGARTEN-SETTING? Zahner, L.1, Ernst, D.1, Baumann, A.1, Siebenhaar, N.1, Donath, R.1, Muehlbauer, T.2 1 Institute of Exercise and Health Sciences, University of Basel, Switzerland 2 Institute of Sport Science, Friedrich-Schiller-University Jena, Germany Introduction Due to an increase in sedentary behaviour (e.g., increase in media consumption, decrease in physical activity), basic public health physical activity recommendation cannot be achieved by the general population mainly in western societies. However, physical inactivity contributes to high prevalent chronic diseases such as obesity, coronary heart disease, and diabetes. This is of even greater importance, since childhood inactivity frequently maintains into adulthood (McMillan and Erdmann, 2010). Therefore, promoting health-related physical activity habits in pre-school children should be highlighted in present public health considerations. Thus, we assessed the effectiveness of a short bout physical activity program in pre-school children. Methods Pre-school children (N=217) were randomly assigned into control (C) and intervention (I) groups. Matching criteria were set by age, gender, height, and mass. The intervention group underwent a 15 minute exercise program per day on agility, balance, and strength performance. The program lasted for 7 months. Interventions as well as pre

and post testing took place at pre-school. Tests consisted of three subsets: agility running test, repetitive jump test and dynamic balance test (Bös, 1987). Performance data were z-transformed and the z-scores were used within mixed linear models. Results The adjusted differences in post testing are substantial concerning agility running (I, 17.1±3.8 to 15.5±2.6 seconds vs. C, 18.7±4.5 to 17.2±2.6; -0.39 seconds from pre to post; -0.39 (-0.68 to -0.09 CI), p=0.013) and repetitive jump testing test (I, 36.3±12.0 to 46.3±12.0 repetitions vs. C, 31.0±10.4 to 37.9±9.6 repetitions from pre to post; 0.43 (0.15 to 0.72 CI), p=0.005). In contrast, dynamic balance tests did not reveal any changes between pre and post testing in both groups. Also waist circumference and fat-free mass did not decrease significantly. Discussion A regular and short term basic physical activity program in a pre-school setting considerably increases agility running and jumping performance. Postural control did not benefit in an appropriate manner. The latter might be caused by age-related baseline varieties of postural sway. We therefore conclude that a daily amount of 15 minutes is not sufficient for postural control improvements but leads to adequate improvements in fundamental motor skills. Further studies should therefore focus on longer periods of exercise programs and maintaining exercise in adulthood depending on pre-school activities. References McMillan CS, Erdmann LD. (2010). *Pediatr Exerc Sci*, 22(2), 231-244. Bös K. (1987). *Handbuch motorische Tests*. Hogrefe Verlag, Göttingen.

### PP-SH02 Exercise Psychology

#### EFFECT OF HIP-HOP DANCE TRAINING ON EMOTIONAL PROCESSING IN HEALTHY YOUNG ADULTS.

SENSUI, H., NAGAMATSU, T., SENOO, A., MIYAMOTO, R., NORIUCHI, M., SUGIMOTO, M., FUJIMOTO, T., KIKUCHI, Y.  
MEIJI YASUDA LIFE FOUNDATION OF HEALTH AND WELFARE

There is increasing evidence that exercise can improve symptoms of depression. Recent neuroimaging studies have suggested that abnormal neural responses to emotional stimuli appear in depressed patients, and the neural substrates underlying antidepressant treatment have studied. However, there are few studies about exercise. In the present study, we examined the effect of exercise training on neural response to happy and sad emotional stimuli using functional magnetic resonance imaging (fMRI) technique in healthy young adults. Methods: Twenty-two university students who did not regularly exercise and were not under clinical treatment were assigned to training (7 men and 4 women) and control (5 men and 6 women) groups. The training group performed short-term hip-hop dance training consisting of a 60-min class 3 times per week for 3 weeks. The control group maintained their daily activity. Functional MRI was acquired during the screening of pleasant, unpleasant, and neutral slides at the pre- and post-training periods. Neural response to happy (pleasant versus neutral) and sad (unpleasant versus neutral) emotional processing was calculated. Results: The results showed that the neural response to happy stimuli was enhanced by hip-hop dance training (group-by-time interactions were observed) in regions such as the extrastriate cortex, insula, temporal pole, and putamen. On the other hand, a few regions including posterior parietal region showed an increased brain response in the sad condition. Discussion: Enhanced extrastriate activity to happy emotional stimuli was considered as increased attention to happy emotional stimuli. In addition, activation of insula and putamen are associated not only with emotional feelings but also body states (including visceral sense). The present study suggested that exercise may improve anhedonia, which is core symptom of depression, by changing attention and body reaction to happy emotional stimuli.

#### PASSION FOR DANCE: A NEGATIVE DEPENDENCY THAT ENHANCES RISKY BEHAVIOUR?

AKEHURST, S.1, LESZCZYNSKA, O.2, OLIVER, E.2  
1 UNIVERSITY OF DERBY & 2 ABERYSTWYTH UNIVERSITY

Passion is a strong desire toward an activity that is self-defining, of utmost importance, and receives a vast investment of time and effort from an individual. Grounded within self-determination theory, harmonious and obsessive passion are proposed, with the former more positive, and the latter negative in nature (Vallerand et al., 2003). Obsessive passion has been associated with increased injury and injury-related risky behaviour in dancers (Rip et al., 2006), which supports the negative connotations proposed. The current research set out to test whether exercise dependence can explain the obsessive passion – risky behaviour relationship. Participants were 100 (50 fs; 50 ms) professional dancers ranging from 18 to 25 years of age (M = 20.88; SD = 2.69). With institutional ethical approval, participants completed informed consent, self-ratings of risky behaviours (doctor visits; following treatment, and warming up) and two psychological measures: Passion for Dance Scale (Rip et al., 2006) and Dance Dependence Scale (adapted from Hausenblas & Downs, 2002). Findings revealed a positive correlation between dance dependence and both harmonious ( $r = .42, p < .01$ ) and obsessive passion ( $r = .72, p < .01$ ). However, only obsessive passion and dance dependence correlated with two risky behaviours (low doctor visits and not following treatment). Dance dependence fully mediated the relationship between obsessive passion and doctor visits, and between obsessive passion and following treatment. Findings provide further support to the negative associations of obsessive passion in terms of risky behaviour in dance (Rip et al., 2006), but also offer initial evidence that exercise dependence may explain this relationship. Results are discussed in light of self-determination theory and the benefits and dysfunctions of passion for dance. The current findings suggest that professional dancers are at risk of employing maladaptive behaviours in terms of training and injury if they report high levels of obsessive passion, which may be detectable via the symptoms of exercise dependence. Future research is recommended in terms of the obsessive passion – exercise dependence relationship. Hausenblas, H. A., & Downs, D. S. (2001). How much is too much? #### THE PREVALENCE OF EATING DISORDERED PSYCHOPATHOLOGY AND BEHAVIOURS AMONGST BRITISH ATHLETES

SHANMUGAM, V., JOWETT, S., MEYER, C.  
LOUGHBOROUGH UNIVERSITY

THE PREVALENCE OF EATING DISORDERED PSYCHOPATHOLOGY AND BEHAVIOURS AMONGST BRITISH ATHLETES Shanmugam, V.1, Jowett, S. 1, Meyer, C. 2. 1: School of Sport, Exercise and Health Sciences (Loughborough, England), 2: Loughborough University Centre for Research into Eating Disorders (Loughborough, England) Introduction Athletes are considered to be at higher risk of developing eating

disorders than the general population; however the prevalence of eating disordered psychopathology and behaviours amongst British athletes is unknown. Therefore the central aim of the present study was to determine and compare the prevalence of self-reported eating disordered psychopathology and behaviours in elite, developmental and recreational British athletes against a sample of British non-athletes, as well as examine gender differences across and within performance levels. Methods A random sample of 945 British athletes and 186 British non-athletes completed the Eating Disorder Examination Questionnaire (EDEQ). Results Six percent of elite athletes, 5.9% of developmental athletes, 9.9% of recreational athletes and 12.4% of non-athletes were classified as potential cases with eating disorders. Significant gender differences were found between female athletes and female non-athletes across the four performance levels, as well as between males and females within each performance level. Discussion The current findings provide evidence to suggest that eating disorders are more common amongst the general population than athletes, with female non-athletes identified as at high risk. However, males and females who engage in sports for a recreational purpose may be at a higher risk of developing an eating disorder than competitive athletes.

### THE ACUTE EFFECTS OF PHYSICAL ACTIVITY ON CIGARETTE CRAVINGS: A META ANALYSIS WITH INDIVIDUAL PARTICIPANT DATA

HAASOVA, M.1, JANSE VAN RENSBURG, K.2, FAULKNER, G.3, USSHER, M.H.4, WARREN, F.5, TAYLOR, A.H.1

1:UEXETER(UK), 2:MOFFITT INST,(USA), 3:UTORONTO,(CAN), 4:SGUL,(UK), 5:PCMD,(UK)

Introduction Strength of urge to smoke is one of the strongest predictors of smoking cessation (Fidler et al, 2010) and exercise acutely reduces Strength of Desire (SoD; West et al, 1989) to smoke (Taylor et al, 2007). The study aims to provide an up to date review and collate Individual Participant Data (IPD; Riley et al, 2010) for SoD following exercise (versus rest), and to identify predictors of craving reduction. Methods Sixteen randomised parallel group or crossover design studies met the inclusion criteria. Original data from the authors for SoD and a range of demographic & behavioural measures were collated. A two-stage IPD meta-analysis was performed using data from 8 parallel arm trials and randomly selected data from 7 crossover trials, using a random effects model. Participants engaging in physical activity (PA) were compared against control participants, using the difference between post-intervention and baseline SoD. Followed by a linear regression of post-PA SoD with demographic & behavioural covariates, adjusting for study and baseline SoD. All analyses used Stata v.11. Results For the two-stage meta-analysis, the pooled estimate for treatment effect (non-standardised mean difference) was -1.908 (95% CI -2.721; -1.095), with a high degree of between-study heterogeneity. IPD with SoD & covariates were available for participants engaging in a PA intervention in 14 trials. Age, smoking years, cigarettes per day (CPD) and carbon monoxide were significant individually ( $p < 0.05$ ). Data for carbon monoxide and smoking years were only available from 8 & 9 studies respectively. Age was highly correlated with smoking years ( $r = 0.93$ ), so used as a proxy. A model including age and CPD was considered the most appropriate ( $n = 350$ ). The regression coefficients for age and CPD were -0.026 (95% CI -0.045; -0.007;  $p = 0.006$ ) and 0.038 (95% CI 0.011; 0.066;  $p = 0.006$ ), respectively. Gender, body mass index, PA status, Fagerström Test for Nicotine Dependence (Heatherton et al, 1991), duration of abstinence, were not associated with post-PA SoD. Discussion This is the first analysis investigating factors moderating acute effects of PA on cigarette cravings. Future analysis should consider how best to integrate data from both parallel group and crossover design studies. References Fidler JA, Shahab L, West R. (2010). *Addict*, 106, 631-8. ### COMPARATIVE ANALYSIS OF ANXIETY AND DEPRESSION LEVELS IN CHILDREN SUFFERING FROM DIFFERENT DEGREE SCOLIOTIC

KOVALENKO, T., SHKLYARENKO, A., JAHNIK, J., ULYANOV, D., POPKOV, A.

VOLGOGRAD STATE UNIVERSITY

COMPARATIVE ANALYSIS OF ANXIETY AND DEPRESSION LEVELS IN CHILDREN SUFFERING FROM DIFFERENT DEGREE SCOLIOTIC KOVALENKO T., SHKLYARENKO A., JAHNIK J., ULYANOV D., POPKOV A. Volgograd State University Slavenskiy-on-Kuban Pedagogical State Institute, Russia Introduction. The unbalance of nervous processes can lead to anxiety and depression. In work with children suffering from locomotor apparatus diseases, it is especially important to reveal in time the psychotic disorders and to prescribe the required rehabilitation procedures. Methods. The present study was carried out in the Children's Orthopaedic Sanatorium. Fifty six adolescences, aged 12-14, were examined. The following four groups of children with different scoliosis degrees were revealed: fault in posture; scoliosis of first degree; scoliosis of second degree; scoliosis of third degree. Each group of children was tested to detect their anxiety and depression levels. It should be noted that the coefficients algebraic sum exceeding +1,28 is indicative of good mental state. The sum minor to -1,28 shows the expressed psychologic stress, anxiety and depression. Results and their discussion. Analyzing the data obtained, we observe the absence of evident depression condition in examined children of all groups. Moreover, the positive mental state is detected in the first, second and third groups. Intermediate value of depression rate is found in children with the second degree of scoliosis (the fourth group). The average coefficient of anxiety and depression levels is 1,95 which goes to prove good respondents mental state. The present research shows that children aged 12 have decreased anxiety and depression levels. This result gives evidence of age-specific positive mood. Children aged thirteen have positive indicator of depression rate as it is also decreased. The anxiety rate is indefinite. Children aged fourteen are indefinite level of anxiety and depression. The data obtained indicates the rise in emotional stress with advancing age. Conclusion. By this means, with the increase of years, children suffering from scoliosis of different degrees have rising mental stress level that may adversely affect children's treatment course as well as their socialization.

### PP-SH03 Notational and Performance Analysis

#### CONTEXTUAL EFFECTS ON THE TEAMS' PERFORMANCE IN DEFENCE-ATTACK TRANSITION IN ELITE FOOTBALL

VOLOSOSVITCH, A.I., TOJO, O.I., CARITA, A.I.I., FERREIRA, A.P.I.

TECHNICAL UNIVERSITY OF LISBON FACULTY OF HUMAN KINETICS

**Introduction** The influence of contextual factors of competition on the different aspects of teams' performance in football received a large research interest recently (Bloomfield et al., 2005; Taylor et al., 2008). Transition from defence to attack represents a crucial phase of the offensive process. Consequently, the analysis of factors that influence transition game efficacy in different competitive contexts can help to make the match analysis more objective. This study aimed to assess the effect of match status and quality of opposition on the organization and subsequent success of the team in defence-attack transition sequences. **Methods** The sample consisted of 570 defence-attack transition sequences from the 24 matches, played by the 4 best classified teams of the 2010 FIFA World Cup. The observation system, developed for this study, included 16 categories and 67 performance indicators that were analyzed in function of two contextual variables – match status and quality of opposition. Multinomial Logistic Regression was used to determine which and how performance indicators were associated with different levels of teams' success in defence-attack transition sequences (0 – lost the ball possession, 1 – shooting the ball behind the opponent's goal, 2 – shooting the ball into the opponent's goal) in different match contexts. **Results** The results showed that there were five categories associated with teams' success in defence-attack transition game: the zone of attack finalization ( $p \leq 0,001$ ); attack-defence numeric relationship in finalization phase of attack ( $p \leq 0,001$ ); the first pass direction after the ball possession recovery ( $p \leq 0,010$ ); the attack-defence numeric relationship at the moment of the ball possession recovery ( $p \leq 0,010$ ) and the quality of opposition ( $p \leq 0,010$ ). The match status did not show any significant effect on the teams' performance in transition game. **Discussion** It was concluded that quality of opposition had significant effect on the teams' performance in defence-attack transition sequences. When the teams played against weaker opponents, they created more succeed transition sequences, which ended with kicks from penalty area in numeric superiority situations. The absence of match status effect on the teams' performance in transition game might be explained by the high equilibrium of observed matches. **References** 1) Bloomfield, J. #### VALIDATION OF SPACE PROTECTION DYNAMICS IN BASKETBALL DEFENSE

LAMAS, L., SANTANA, F., ROSTAISER, E., UGRINOWITSCH, C.

SCHOOL OF PHYSICAL EDUCATION AND SPORT - UNIVERSITY OF SAO PAULO

**Introduction** In a basketball match two teams interact dynamically in order to disrupt the defense and score or to prevent the opponent from achieving the goal. The set of a team's offensive dynamics to disrupt the defensive system has been recently described (Lamas et al., 2011). However, the correspondent set of dynamics the defensive team may perform to contain the offense and protect the space has been not elaborated yet. Our aim was to validate a set of space protection dynamics (SPDs) that contemplate all defensive possibilities of a team. **Methods** SPDs classes contemplate all possible defensive reactions to 1x1, 2x2 and 3x3 offensive actions in basketball. Validation followed Fonseca's et al. (2008) procedures: 1a. Proposition of a model of SPDs classes based on researchers experience (ten years in match analysis field) and analysis of ten matches from the male tournament of Beijing'08 Olympic Games; 1b. Conceptual improvement: SPDs criteria were analyzed by three international class pro-coaches, who evaluated its description for consistency; 1c. Intra and inter-observers reliability tests were performed by three blind expert judges (three observation rounds, one week apart each); 1d. Application of the SPDs: analysis of 2000 ball possessions from pro-matches for verifying the completeness of the instrument. **Results** Resultant classes of SPDs (steps 1a-b): 1x1 defense: Neutral; Restricted (inducing the offensive player to a side). 2x2 defense of without ball displacements: Close; Spaced. 2x2 pick'n'roll on ball defense: Together (pass the screen as the second player); Middle (third player); Behind (fourth player); Trap; Switch; Reject. 2x2 pick'n'roll screener defense: Show; Open; Push; Switch; Trap. 3x3: Screen Away receiver defense: Together (second); Middle (third); Behind (fourth); Switch; Reject. Screen Away screener defense: Show; Open; Push; Switch; Bump. Kappa test (step 1c) presented scores higher than 0.80 of agreements between and within judges. Defensive behaviors of all ball possessions analyzed (step 1d) were classified in a SPD category, indicating adequate completeness of the instrument. **Discussion** The validation of the SPDs classes was successfully performed. For all 1x1, 2x2 and 3x3 offensive actions there was provided a respective defensive class of action to protect space. The theoretical analysis of specialists contributed to the improvement of the instrument and any empirical inconsistency was detected. The SPDs and the offensive dynamic classes provide a more complete possibility for evaluating the opposition process in basketball. **References** Fonseca, R, Salles, J, Parente, M. #### STATISTICAL ANALYSES OF FEMALE BASKETBALL TEAM PERFORMANCE: TURNOVERS ACCORDING TO OFFENSIVE AND DEFENSIVE TACTICS.

TSAMOURTZIS, E., FYLAKTAKIDOU, A., KARIPIDIS, A., MAVRIDIS, G.

DEMOCRITUS UNIVERSITY OF THRACE

**Introduction** The turnovers, shots and fouls constitute the effectiveness of offense (Filaktakidou et al., 2003). Turnovers occur more often than you might imagine, especially taking into account the level of skills of today's players. Their display frequencies, is the main culprit for the reduction of offensive percentage, and even more than the percentage of shots and rebounds. The minimizing of turnovers should be the main concern of the offense to achieve a victory (Mikes, 1987). This research was done with the aim of recording and the analysing of turnovers and their role in shaping the outcome. Also, it was to study the interaction of turnovers in game situations (offensive tactics, defense tactics). **Methods** For the purpose of this study forty-three ( $n=43$ ) women A1 National league basketball games were videotaped and video-analyzed. The method of indirect observation was employed and "Sportscout" program were used for the analysis of the digital video (Tsimpiris A., Tsamourtzis E., Sfingos N., Zaggelidis G., Zaggelidis S., 2006). Statistical analysis of this data included the presentation of frequencies in a double table and the application of  $\chi^2$ . **Results** The results showed that a) 19,1% of the possessions stop after a turnover, b) the most common turnover to the women basketball is the passing errors. Travelling and fault ball handling follow, c) most of the turnovers happen during the set play, d) the ability to defeat the zone defense is of a real importance because the women basket-

ball teams use to play this defense and most of the turnovers seems to happen under these circumstances. Discussion In the future, the coaches should spend more time practicing passing skills and ball handling, if they want to reduce their team's turnover percentages and improve significantly their offensive performance, as reducing the turnovers means increasing the chances of effective ball possession. While taking into account the areas of the court where the turnovers occur and the type of turnover that occurs in each area, enables the coaches of the women's teams to prepare most effective systems, adapted specifically to women's basketball and to organize and guide better their practices. Also, we believe that the coaches of women's basketball should dedicate more time practicing defense zone because this strong defense zone is one fact that could affect the result of the game. Respectively speaking, there should be very good preparation by the team to deal with defense zones as they are commonly used in women's basketball. References Filaktakidou A., Tsamourtzis, E. Taxildaris K., (2003). *Woman and Sport*, II (1):73-84. Mikes, J. (1988). *Scholastic Coach*, 57(6): 82,84. Tsimpliris A., Tsamourtzis E., Sfigos N., Zaggelidis G, Zaggelidis S. ### THE RECOVERY OF BALL POSSESSION IN DIFFERENT MATCH CONTEXTS. A CASE STUDY WITH THE PORTUGUESE PROFESSIONAL SOCCER TEAM

VOLOSOSVITCH, A.1, ANDRADE, C.1, CORBELLINI, F.1, CARITA, A.1.1, FERREIRA, A.P.1

TECHNICAL UNIVERSITY OF LISBON FACULTY OF HUMAN KINETICS

**Introduction** Previous research has shown that the performance in sports games is influenced by the context of the competition (Lago, 2009; Taylor et al., 2008). Therefore, the valid assessment of performance should consider the quality of opposition and evolving status of match. This study aimed to identify the team's actions that led to the recovery of ball possession and analyze the further evolution of offensive sequence in different match contexts. **Methods** The sample consisted of 801 occurrences of ball possession recoveries from 10 matches of the Portuguese Professional Soccer League and Portugal Cup 2009/2010. The observation system included 8 categories and 47 performance indicators. All indicators were analyzed in function of two contextual variables - match status and quality of opposition. Binomial Logistic Regression was used to determine which and how performance indicators were associated with the dichotomous variable first pass direction (1 – forward pass, 0 – sideward or backward pass), in the different match contexts. **Results** The final model of logistic regression analysis included 3 variables associated with the first pass direction: the zone and the form of the ball possession recovery, as well as the area from where the first pass was made ( $p \leq 0.001$ ). The models estimated for different levels of quality of opposition included the same variables. **Discussion** The association between these 3 performance indicators and forward pass was higher, when the team played against outside opponents. As far as the match status effect is concerned, the variables included in the model had significant effect on the first pass direction only when teams were drawing ( $p \leq 0.001$ ). In draw situation the team preferred sideward and backward passes and showed less offensive attitude. The results suggested that the form and zone of recovery of ball possession, as far as the first pass direction, were influenced by the quality of opposition and evolving score. Thus, these contextual variables should be taken into account in teams' performance analysis. **References** 1) Lago (2009). *J Sports Sci*, 27(13): 1463-1469. 2) Taylor, J. B., Mellalieu, S. D., James, N. & Shearer, D. A. (2008). *J Sports Sci*, 26, 885-895.

### GAME LOCATION EFFECTS IN ELITE SOCCER

LAGO-PÉÑAS, C.

UNIVERSITY OF VIGO

**INTRODUCTION** Home advantage in sport has been the subject of much empirical work, although the causes underlying this effect are still unclear. However, few studies have directly examining whether the fundamental measures of match performance (i.e. technical and tactical aspects) differ as a function of match location (e.g. Lago and Martin, 2007; Sasaki et al., 1999). As a consequence, in the present study game location effects upon technical and tactics-related statistics were investigated in all the 380 matches of the 2008-2009 Spanish Soccer League. **METHODS** The examined sample consisted of 380 Spanish Soccer League First Division matches played throughout the 2008-2009 season. The collected data were provided by a multiple-camera match analysis system (Gecasport). The following game-related statistics were gathered: total shots, shots on goal, effectiveness, assists, crosses, offsides committed and received, fouls committed and received, corners, passes, successful passes, ball possession, crosses against, dribbles, yellow and red cards. Data were analysed through descriptive and inferential procedures. Independent student t-test was used to identify the differences in all performance indicators between each team's home and away. A discriminant analysis was conducted to find the statistical team variables that discriminate among home teams and visitors. Finally, Pearson coefficients of variation (CV) were calculated for each variable depending on the final league ranking of the teams. **RESULTS** An overall home advantage was found for the sample in relation to home-winning and home-goal percentage. For technical performance more passes, successful passes, dribbles, and corners were performed by home teams. Home teams spent more time in possession of the ball than visitors. Finally, the top-placed teams showed lower CVs for the analyzed variables per match compared to those who finished lower in the table. **DISCUSSION** Overall, the findings suggest that in addition to influencing match outcome (i.e. home win percentage) the home advantage in terms of behavioural and strategic effects appears to exist at an individual team level within soccer. The results partially confirmed the predictions that more successful technical and tactical performance indicators would be performed at home compared to away (Taylor et al, 2008). Future research should consider the influence of other confounding variables such as weather conditions, game status, team form and opposition quality. **REFERENCES** Lago C, Martin R. ### ANALYSIS OF TACTICAL SITUATIONS OF ELITE TURKISH TENNIS PLAYERS IN TERMS OF "5 GAME SITUATIONS"

KILIT, B., SUVEREN, S., ŞENEL, Ö.

1: İNÖNÜ UNIVERSITY, SCHOOL OF PHYSICAL EDUCATION AND SPORT (MALATYA/TURKEY), 2-3: GAZI UNIVERSITY, SCHOOL OF PHYSICAL EDUCATION AND SPORT, (ANKARA/TURKEY)

**Introduction** Tennis is a dynamic and complex sport in which there are recurrent positions and strokes. The strategic plans of the players help them make planning against their rivals' strong and weak sides, and adapt to the forthcoming tournaments (10). The limited studies made until now to analyze the tactical aspects of the Turkish Tennis players are remarkable. This study was done to determine the tactical game situations of the elite Turkish Tennis players in terms of "5 game situations". **Methods** The data were obtained by examining the

video records of 94 matches which were played by 108 players (44 female, 64 male) in the senior category in the Championship of Turkey. The statistical analyses were carried out with SPSS 15.0. Results It was seen at the end of the study that when the percentage changes of the winning and loss strokes of the Turkish tennis players were examined in terms of 5 games situations, the winning stroke percentages of female tennis players are as follows: serve 42%, baseline play 39, 2%, return of serve 12,7%, playing against a net player 2,2%, net play 3,9%, while their loss strokes are serve 8,4%, baseline play 61%, return of serve 27,6%, playing against a net player 1,2%, net play 1,8%. The winning stroke percentages of male tennis players are as follows: serving 45,4%, baseline play 30,5 %, return of serve 4,8%, playing against a net player 4,3%, net play 15%, while their loss strokes are serve 7%, baseline play 59,3 %, return of serve 25%, playing against a net player 4,1%, net play 4,6%. Discussion As a result of the research, female tennis player are generally successful in serving, baseline play, however they have high error ratio in baseline play and return of serve. Although Male tennis players are successful in serving and baseline play, they have high error ratio in baseline play and return of serve. Finally, the tennis players with fewer error strokes are more successful at matches. References Ingram B. O'Donoghue P. ### CASE-BY-CASE ANALYSIS OF GAME INTERRUPTIONS IN FOOTBALL

LAMES, M.

TU MÜNCHEN

Introduction There are many studies on effective match time in soccer showing that about one third of the total time the game is interrupted (e.g. Meyer, et al., 2000). Drust, et al. (2000) simulated the loads imposed on football players during a soccer match using a treadmill-protocol. This study analyses the demands of a football match by a case by case examination of each game interruption in order to obtain a more precise description of the intermittent nature of a football match. Methods 16 matches of a German first league football team were analysed. To characterize the intermittent nature of a football match, the status of the match was coded (1 = running; 0 = interrupted) for every second. A forward moving average (length 120 seconds) was computed to describe the local relation between the two states. Results Results are given for a typical match. There are several phases in the game with a rather high proportion of interrupted match (>50%) although no interruption lasted for longer than two minutes. On the other hand we find six occasions of running match lasting longer than 2 minutes. Mean interrupted match time (28%) is almost never typical for the local interrupted match time. Instead, the moving average is characterized by large variations in match status thus reflecting typical behaviour in football. These results were found similarly in all 16 matches. Discussion Case-by-Case analyses of interruptions improve the understanding of the intermittent load characteristics in football. It turns out that mean interrupted match time is an inappropriate estimate for local match load. A player faces large, unforeseeable variation in running and interrupted match times. The methods presented gives valuable hints for the practical preparation of the players, because it informs on the respective durations of demanding and recovery match intervals. ### DO NATIONAL TEAMS IN THE FIFA WORLD CUP PLAY DIFFERENTLY? MATCH ANALYSIS OF SOUTH AFRICA 2010.

CASCONI, S.I, D'ARTIBALE, E.I, DI CAGNO, A.I, CALCAGNO, G.I

UNIVERSITY OF MOLISE

Introduction: Teams participating in the FIFA World Cup (FWC) differ in level, technical and tactical characteristics. The FWC games are organized according to the official FIFA ranking. Match performance analysis of the highest ranked teams (HRT) and the lowest ranked teams (LRT) could reveal the differences in playing and highlight the technical aspects and tactical attitudes. The aim of this study was to examine the data of the matches of different FIFA ranking teams during the FWC in South Africa in 2010. Methods Sixteen national teams (n°8 HRT and n°8 LRT according to 2009 FIFA ranking) while playing the FWC 2010 were taken in consideration in this analysis. Data were collected from official FIFA reports (www.fifa.com). Data of final match results, goals, shots, corners, fouls, cards, ball possessions, actual playing times, correct and wrong passes (short: <10mt; medium: 10-29.99mt; long ≥30mt; cross), distance covered and running average speed of the team players were collected for each match. Descriptive analysis and chi square test analysis were used. Results A total of 69 matches were analyzed (n°41 HRT and n°28 LRT). HRT resulted to be higher than LRT in mean of goals scored, shots and shots on goal, corners, ball possession, actual playing time and number of passes (600 passes for each match for HRT vs 463 for LRT). In particular, HRT differed from LRT in number of correct passes: short 102.2±32 (HRT) vs 78.6±23 (LRT); medium 283.3±77 (HRT) vs 176.1±49 (LRT); long 52.2±16 (HRT) vs 43.2±13 (LRT); and crosses 4.7±3 (HRT) vs 3.2±2 (LRT). Total distance covered by teams during defined passage of play was 7708.2±609 mt for HRT and 7886.5±847 mt for LRT; and the same value of average players' top speed was found: 22.3±1.2 Km/h for HRT and 22.3±0.8 Km/h for LRT. The ball possession was 47.7%±6 for losing teams, was 49.8%±6 for teams that tied the match, and 53.7%±6 for winning teams. Discussion This study showed differences in match data of national teams ranked by FIFA and participating at the 2010 FIFA World Cup. Results showed a relationship between the percentage of ball possessions and final match outcomes. As well, data showed differences in technical aspects about the number and the accuracy of passes shorter than 30 mt, that could represent fundamental general direction for training. Match performance analysis of teams differently ranked by FIFA could reveal information about technical and tactical attitudes that can improve the soccer game development. ### ANALYSIS OF THE DEFENSIVE COVERAGE IN HIGH-LEVEL VOLLEYBALL. A PRELIMINARY STUDY OF THE LIBERO PLAYER IN A SPANISH TOURNAMENT

HILENO, R.I, BUSCÀ, B.2

1: INEFC LLEIDA; 2: PSYCHOLOGY, EDUCATION AND SPORT SCIENCES FACULTY OF BLANQUERNA

Introduction Spiker coverage is a defensive action present in all Game Complexes performed by the team in possession of the ball (Rodríguez et al., 2011). From setting to spiking, players who don't complete the attack change their location on the court to cover the spiker (Meier, 1994). A limited number of balls coming from block touch could be defended by the team with this action (Selinger & Ackermann-Blount, 1992). The aim of this study was to detect patterns of spatial behaviour between libero and attacker players during the Complex I. Methods 325 actions were registered from a randomized sample of the 2009 Queen's Cup, held in Menorca (Spain). A high-speed video camera (300 Hz) was used to record the rallies of 7 matches between the 8 best teams of the season. Overlay image

and frame by frame analysis were performed using the video analysis software Kinovea to determine the players' location while attack was completed. Synchronic analyse in lag 0 was carried out in the statistical software GSEQ to detect patterns of interactive behaviour. The 5 attack zones referring to the Attacker's Location (AL) and the 6 cover zones concerning to the Libero's Location (LL) were selected as givens and targets behaviours, respectively. Results 5 stable patterns of interactive behaviour were identified. The first between given Attacker's Location in Zone 4 and target Libero's Location in Zone 4 ( $Z=7.57$ ;  $p<.01$ ). The second between ALZ3 and LLZ1 ( $Z=4.19$ ;  $p<.01$ ), LLZ5 ( $Z=2.31$ ;  $p<.02$ ) or LLZ6 ( $Z=2.15$ ;  $p<.03$ ). The third between ALZ2 and LLZ2 ( $Z=9.66$ ;  $p<.01$ ) or LLZ3 ( $Z=2.08$ ;  $p<.04$ ). The fourth between ALZ6 and LLZ1 ( $Z=2.62$ ;  $p<.01$ ). And the last one between ALZ1 and LLZ3 ( $Z=3.1$ ;  $p<.01$ ). Discussion The results are agree with the idea that volleyball players should take a specific coverage responsibility area for each particular attack zone (Selinger & Ackermann-Blount, 1986). The Liberos are located at the front zones of the court (4, 3 and 2) to cover spikes in lateral zones (4, 2 and 1). Moreover, they cover in back zones (5, 6 and 1) with spikes in central zones (3 and 6). In addition, the Liberos and Attackers are located at the same area only when spiking in front lateral zones (4 and 2). In these situations the Liberos cover near the Attackers. References Meier, M. (1994). Movement dynamics in volleyball with young players. *International Volley Tech*, 1(94), 11-16. Rodríguez, D., Quiroga, M.E., Miralles, J.A., Sarmiento, S., De Saá, Y., García, J.M. (2011). ## CHARACTERISTICS OF THE RUNNING PERFORMANCE IN JAPANESE PROFESSIONAL SOCCER PLAYERS

ISHIZAKI, S.1, YASUMATSU, M.2

1) SHIBAURA INSTITUTE OF TECHNOLOGY, 2) RIKIKYO UNIVERSITY

**Introduction** In time-motion analysis of soccer games, many researchers have been analyzing quantity of the distance covered in soccer players (Bangsbo et al. 1991). However, the previous data used for their analysis were collected only from players in European top-level soccer club or national teams. Actually, there was no studies used the data from Japanese professional soccer players. Therefore, the purpose of this study was to assess running performance in Japanese professional soccer players. **Methods** This study was carried out with sixteen J-League (Division 1) games in 2010 season. Thirty-two professional Japanese soccer players (age:  $25.7 \pm 4.0$  years, height:  $177.3 \pm 5.4$  cm, body mass:  $71.8 \pm 5.5$  kg) participated in this study, including defenders ( $n=12$ ), midfielders ( $n=12$ ), and forwards ( $n=8$ ). These players were filmed during the entire match. The digital video cameras (HDR-XR550V, Sony, Japan) were positioned at the side of the pitch, at the level of midfield line, at a height of about 20m and at a distance of about 30m from touch line. The digital movies were later replayed on a monitor. Then, total distance and running speed were analyzed using Track Performance software (Sports Code, Australia). This software system was applied most effectively with the use of a drawing tablet (PTK-1240, Wacom, Japan) connected to laptop computer. The locomotion categories were used for standing (0km/h), walking (6km/h), jogging (8km/h), low-speed (LS) running (12km/h), moderate-speed (MS) running (15km/h), high-speed (HS) running (18km/h), sprinting (30km/h). These locomotion categories were chosen in accordance with Bangsbo et al. (1991). **Results & Discussion** The mean total distance covered in 90 min. was  $11265 \pm 700$  m and ranged from 9740m to 12370m. The average distance covered (absolute & relative data) consisted of standing (0m, 1.4%), walking (2439m, 46.1%), jogging (1790m, 15.7%), LS running (3405m, 21.7%), MS running (1817m, 8.5%), HS running (1016m, 3.9%), and sprinting (802m, 2.7%). There was no significant difference between the first ( $5640 \pm 400$  m) and the second ( $5626 \pm 400$  m) half of the total distance covered (absolute data). However, relative data in the second half regarding standing and walking were significantly increased compared to the first half ( $P<0.05$ ). On the other hand, jogging, LS running, MS running, HS running, and sprinting were significantly decreased compared to the first half ( $P<0.05$ ). Therefore, it was suggested that fatigue accumulated in Japanese professional soccer players during the games affected faster running speed especially in the second half. **References** 1. ## MASCULINITIES AND BODIES: THE IMPORTANCE OF PHYSICAL ACTIVITIES TO ELDERLY MEN

CARVALHO, J.1, BOTELHO-GOMES, P.2, NOVAIS, C.1, QUEIRÓS, P.2, SILVA, P.2

UNIVERSITY OF PORTO

**Introduction** To be a man or to be a woman is not an acquired state – it is rather an appropriation, a condition in permanent active construction, which involves tensions and ambiguities (Vale-Almeida, 1996). And masculinity, beyond being perceived as a social process, involves practices which refer to the body and what the body does (Connell, 2000). With advancing age, elderly identities, especially masculine identity has perforce to be realigned due to the possible loss of sexual performance, reduced muscle power and strength and the onset of illness and frailty (Arber, Davidson & Ginn, 2003). This concern with physicality and body's functionality may encourage older man toward healthy activities, such as physical activity, exercise or sports (Halliwel & Dittmar, 2003). However, the literature that analyze the influence of regular exercise in older men perceptions of their "old or renew" masculinity is scarce. In this context, the aim of the present study was to recognize the way elderly men perceived their masculinity and body and how the practice of an exercise program interferes in those perceptions. **Methods** A qualitative approach, employing semi-structured interviews, was used to elicit masculinities and body concerns amongst a group of 10 older men (mean age= $67.8 \pm 5.6$  years old) that began an exercise program. Content analysis technique and interpretation was applied, after data being processed by the program QSRNVivo7. **Results** The results showed: (i) a strong association between masculinity and sexuality; (ii) that aging has an impact in older men masculinity through loss of active sexuality as well as functional and healthy body; (iii) the influence and importance of an exercise program in the masculinity negotiation process, through which man improve their abilities, functionality and therefore their self-perception of their body and masculinity. **Conclusion** The overall findings suggest that masculinity has a strong relation with body and sexuality. However, physical activities help them to renegotiate their masculinities and to regain the significance of a social body in the commitment to an active life style. **References** Arber, S.; Davidson, K. & Ginn, J. ### ATTITUDE TOWARDS PERFORMANCE-ENHANCING DRUGS IN SPANISH SPORT SCIENCES UNIVERSITY STUDENTS

FREIRE, C., MORENTE-SÁNCHEZ, J., FEMIA-MARZO, P., SÁNCHEZ-MUÑOZ, C., ZABALA, M.

UNIVERSITY OF GRANADA

**Introduction** To prevent the wrong use of prohibited substances to improve performance in sport it is important to study first the attitudes towards Doping in athletes, but also in coaches or sport managers and other professionals (1). These attitudes can be mediated by culture, studies, social environment, or the sport practiced (2). The aim of this study was to know the attitude towards performance-enhancing drugs (PED) in Sport Sciences students as well as if it could be any difference due to the sport practiced (individual, team, or both sports). **Methods** The sample was made of 270 students ( $22.09 \pm 3.26$  years) of Sport Sciences degree -Faculty of Sport Sciences, University of Granada (Spain)-. Descriptive design was carried out by means of a validated questionnaire (1) of 17 questions using a Likert scale from 1 (Strongly Disagree) to 6 (Strongly Agree) for different statements that support the use of PED in sport. Three groups were made according to the practiced sport ( $n=27$  Team Sports -TS-;  $n=89$  Individual Sports -IS-;  $n=154$  Both Sports -BS-). Mean value  $\pm$  Standard Deviation was obtained for each item and Mann Whitney test for independent variables was carried out. **Results** In general, the score for the mean of all the items was  $2.04 \pm 0.55$  (2=Through Disagree). The lowest score was observed for the item "Doping is not cheating since everyone does it" with  $1.14 \pm 0.58$ , and the highest for "Athletes are pressured to take PED" with  $3.72 \pm 1.31$  (3=Slightly Disagree; 4=Slightly Agree). Just for one item ("Athletes have no alternative career choices, but sport") significant differences were observed between IS ( $2.48$ ) and the other groups TS ( $2.07$ ) and BS ( $2.00$ )  $-p=0.015-$ . For the rest items no significant differences between groups were observed. **Discussion** Sport Sciences University students in general disagree with the use of PED in competitive sport. In this kind of subjects that are not professionally involved in any of the sports there are no differences in attitudes towards PED due to the sport practiced (TS, IS, or BS), contrary to the hypothesis that argues that those subjects involved in IS are more likely to support the use of these substances (2). Different populations (sedentary, active, or professional) and sports (i.e. Cycling or Athletics Vs Soccer or Basketball) should be investigated in the future to get more patterns about attitudes towards doping in Sport, in relation to the specific sport practiced, frequency of practice, gender, etc. **References** 1. Petroczi, A. & Aidman, E. (2009). Measuring explicit attitude toward doping: Review of the psychometric properties of the Performance Enhancement Attitude Scale. *Psychology of Sport and Exercise*. 10. 390–396. 2. ### DO PREVIOUS STUDIES AND EXPERIENCE AFFECT THE PERSPECTIVE ABOUT DOPING IN THE NEWEST SPANISH CYCLING TEAM MANAGERS?

MORENTE-SÁNCHEZ, J., FREIRE, C., FEMIA-MARZO, P., SÁNCHEZ-MUÑOZ, C., ZABALA, M.

FACULTY OF PHYSICAL ACTIVITY AND SPORT SCIENCES, UNIVERSITY OF GRANADA (SPAIN)

**Introduction** Nowadays the terms 'cycling' and 'doping' are associated (1). Doping cases of some cyclists (2) or the recent 'Contador Case' only emphasize this theory. The aim of this study was to know the perspective of the latest Spanish cycling team managers (highest level) in relation to the phenomenon of doping taking into account their previous level of technical formation and studies. **Methods** The study was composed by a total of 87 participants involved in the course of Cycling Team Manager (Spanish Cycling Federation) in 2009 and 2010. Of the total sample, 15 subjects were graduated in Sport Sciences (Sport Sciences Formation -SS-), 36 had previous federative certification (Federative Formation -FF-), and 36 did not have any technical formation or study but had been previously professional cyclists (No Formation -NF-). A descriptive design was carried out using a specific questionnaire consisting in 7 opened questions, and then answers were analyzed and categorized showing percentage (%) values. **Results** The data obtained (%), comparing the different groups (SSF, FF, NF), were, respectively: 1-Words associated with doping: Cheating (60%, 63.89%, 35.29%); Results/Performance (53.33%, 30.56%, 27.45%). 2- Responsible agents of doping: Laboratories (13.33%, 63.89%, 28%); Coach/Manager (60%, 77.78%, 43.14%). 3-Differences Cycling vs Other sports: Discriminatory treatment (73.33%, 75%, 47.06%); Hardness of cycling (6.67%, 41.67%, 3.92%); Number of controls (26.67%, 30.56%, 9.8%). 4-Reasons for the initiation in doping: Sport achievements (60%, 66.67%, 47.06%); Contract/money (60%, 19.44%, 25.49%); External pressures (33.3%, 47.72%, 37.25%). 5 - Have you been suggested to dope?: SSF (Yes 46.7%); FF (Yes 50%); NF (Yes 72.2%). 6 - Have you seen other people inciting others or being incited?: SFF (Yes 53.3%); FF (Yes 52.8%); NF (Yes 75%). 7 - Proposed solutions: Prevention at early ages (40%, 52.78%, 23.56%); Awareness (33.33%, 25%, 19.1%). **Discussion** Results support the theory that doping is a recognized reality, especially by NF. The SSF group associates 'doping' with 'performance' may be related to get a 'better contract', while FF does the same with 'cheating' possibly caused by 'outside pressures'. Newest managers recognize the main responsible agents involved in the phenomenon of doping. Federative Formation group considers that the main difference between cycling vs others is its hardness, while surprisingly NF does not see the number of controls as a difference with other sports. "Preventing at early ages" and "Awareness of cyclists" by means of psychosocial programs seem to be the most proposed solutions, being SSF group the clearest in this position. In summary, we find different perspectives that suggest that prevention must be taken into account. **References** Lenthion - Kaestner, V. (2008). ### MOTIVATION UNDERLYING BODY IMAGE CONSTRUCTION AMONG BRAZILIAN BODYBUILDERS

SANTOS, A., GUIMARÃES, J.M.M., BAHRKE, M.S., IRIART, J.A.B.

UNIVERSIDADE FEDERAL DA BAHIA

**Introduction** Physical appearance, including male hyper-muscularity, is highly emphasized in today's consumer marketing. Current research studies suggest the cultural norms of the ideal male physique have grown increasingly more muscular (Leit et al., 2002; Leit et al., 2001). The purpose of the present study was to examine aesthetic motivation among young, male Brazilian bodybuilders seeking to improve physical appearance by increasing their body mass and muscularity. **Methods** Employing an ethnographic approach, with in-depth interviews, we qualitatively investigated body image construction among 7 bodybuilders (20-30 yrs of age) in an economically impoverished bodybuilders' gym in Recife, Pernambuco State, Brazil. We used the Discourse of the Collective Subject (DCS) (Lefèvre and Lefèvre, 2003) in order to tabulate and organize the qualitative data obtained during the semi-structured interviews. Adhering to the Theory of Social Representation, this technique permits synthesis of individual narratives – written in the singular, first person – into "one voice" in order to express 'community thought'. In other words, the discourse of seven individuals becomes one. **Results** Principal themes that emerged included "the objective of my workout is to reach perfection" and "friendships influenced my training", among others. The DCS interpretations for these themes are: 'For aesthetic reasons, I decided to practice bodybuilding', 'Definition, perfection, and keeping

my body 'taut' are my goals", "People prefer muscle mass", "I work out very seriously", "I was influenced by friends, a desire for good health, and by seeing other guys working out", and "Other people, especially girls, began to notice". Discussion Le Breton (2006) has proposed that every behaviour can be explained by a particular motivation, reason, aesthetic, ritual, or propitiation. We analyzed the bodybuilders' motivation for aesthetic enhancement (within the theoretical limits of satisfaction and dissatisfaction). Based on our results, we believe this group of bodybuilders – with the apparent purpose of modifying their physiques to meet personal and/or societal expectations – to be more susceptible to high-risk behavioural practices and disorders such as anabolic steroid abuse and muscle dysmorphia. Future research should provide health professionals with effective strategies to address this public health concern. References Le Breton, D. Petrópolis, Rio de Janeiro: Vozes, 2006. #### THE COMPARISON OF LEVEL OF COMPETITIVE ANXIETY IN LORESTAN MALE PROFESSIONAL KARATE PLAYERS AND ITS RELATIONSHIP WITH MATCH RESULT

TATARI, M.1, NAZARIAN, A.B.2, EIZADPANAH, S.3

1: UNIVERSITY OF PAYAME NOOR, KHORAMABAD, LORESTAN, IRAN., 2: UNIVERSITY OF PAYAME NOOR, DELFAN, LORESTAN, IRAN., 3: ISLAMIC AZAD UNIVERSITY, YASOUJ BRANCH, YASOUJ, IRAN

**Abstract Introduction:** It is often seen that some sportsmen, although physically appropriate, are not able to demonstrate their potentialities due to stress and anxiety. Successful sportsmen use anxiety as a stimulator for better performance while less successful ones seem to doubt their performance and be afraid of defeat and, a consequently, they lead themselves to strong fear and anxiety. The aim of this study is to determine the relationship between competitive anxiety and competitive results in karate players. **Materials & Methods:** 150 karate player's (75 kata player's and 75 komite players) participating in championship, were selected. For evaluation of competitive anxiety SCAT inventory was used and completed one hour before the match. The reliability and validity of SCAT have been established in numerous studies. For data analyzes biserial correlation, Pearson correlation and independent T-test were used. **Results and Discussion:** Results showed no significant relationship between competitive anxiety and competitive performance in komite player's ( $P \geq 0/05$ ) but a significant negative relationship was found between competitive anxiety and competitive performance in kata player's ( $P \leq 0/05$ ). In the other hands when the player's competitive anxiety increases their performances degrades significantly. No significant relationship was found between Athlete's experiences in the level of competitive anxiety no significant difference was found between komite and kata players.

#### THE PERCEPTION OF HIGH SCHOOL SENIORS OF THE STUDIES IN THE SPORT UNIVERSITY; THE PROMOTION OF PROFESSIONAL SPORTS AS A CAREER

CARKANJI, V., LLESHI, E.

UNIVERSITETI I SPORTEVE TIRANE

**THE PERCEPTION OF HIGH SCHOOL SENIORS OF THE STUDIES IN THE SPORT UNIVERSITY; THE PROMOTION OF PROFESSIONAL SPORTS AS A CAREER** CARKANJI, V. & LLESHI, E. Sports University of Tirana Introduction The role of sports in society has increased significantly in the past decades and it is being transformed in a major industry that affects many aspects of the economy. Recently, the sport industry has become an extremely profitable sector of the economy (Crockett, 2005). The variety of sport and sport related professions has also increased. The aim of this study was to explore the perception of and interest on sports as a future career path amongst high school students in Albania. We explored student's awareness and knowledge about sports professions, their perception of sports as a career and their wishes to follow such careers. **Methodology** The study was conducted among the senior students of Tirana's high school. We interviewed all seniors in all city's high schools. This is deemed the most efficient method of collecting information from a large number of populations (OGGS web, 2011). The main method of study was a questionnaire survey. Data was collected through face-to-face interviews. **Findings** The study found out that the information and knowledge on sports professions is low amongst high school students. In addition, their perception of sport as a profession is rather negative. As a result, the desire to pursue sports career is also very low. While there were no major differences between female and male students, students with higher academic achievements are less likely to choose a future in sports. We also found that many students are unaware of a number of various sports professions in particular those in the field of sports management. Further research is deemed necessary to explore factors which prevent the high school students senior to join the profession world of sports. **References** Crockett, S. S. (2005). ### THE EFFECT OF YOGA EXERCISE ON MENTAL HEALTH IN WOMEN REFERRED TO YOGA ASSOCIATION OF FARS PROVINCE

EIZADPANAH, S.1, NAZARIAN, A.B.2, AMIRHOSSEINI, E.3, TATARI, M.4

1, 3: ISLAMIC AZAD UNIVERSITY, YASOUJ BRANCH, YASOUJ, IRAN., 2: UNIVERSITY OF PAYAME NOOR, DELFAN, LORESTAN, IRAN., 4: UNIVERSITY OF PAYAME NOOR, KHORAMABAD, LORESTAN, IRAN

**Abstract Introduction:** Yoga is a dynamic method and has a valuable scientific and a practical philosophy used in daily life. The aim of this study is to determine the effect of yoga exercises on mental health in women referred to the yoga association of Fars province. **Materials & Methods:** This is a Quasi – experimental study. 83 women referred to the yoga association voluntarily participated in this study. Inclusion criteria were regular menstruation, lack of amenorrhea, nonsmoking or use alcohol, drugs and hormonal substances or suffered from certain diseases such as epilepsy, hepatitis, etc. yoga exercises composed of Asana, Pranayama and Meditation, these exercise carried out for 12 weeks. The mean age of subjects was 30.4 years with the range of 16-59 years. A modified questionnaire was to data collection and contains the evaluation of emotional excitement, somatic symptoms, anxiety; sever depression, professional ability and feeling of participants before and after the study. Descriptive statistics and T-test were used to analyses data. **Results:** The results of this study show a significant difference between the mental health scales before and after the intervention ( $P < 0.05$ ) and subjects had the better scores for their health after the yoga exercises in all parameters. **Discussion and Conclusion:** Our finding suggests that yoga exercises including Asana, Pranayama and Meditation are useful methods to improve the overall health in women.

### EVALUATION OF PHYSICAL ACTIVITY PROGRAMMES FOR THE ELDERLY IN PORTUGAL - EXPLORING THE LESSONS FROM OTHER SECTORS AND EXAMINING THE GENERAL CHARACTERISTICS OF THE PROGRAMMES

MARQUES, A.I.1, SOARES, P., SOARES-MIRANDA, L.I, MOREIRA, C.I, OLIVEIRA-TAVARES, A.I, CLARA-SANTOS, P.I.2, VALE, S.I, SANTOS, R.I.3, CARVALHO, J.I

1. CIAFEL; 1. RESEARCH CENTRE IN PHYSICAL ACTIVITY, HEALTH AND LEISURE - FACULTY OF SPORTS / U.PORTO; 2. SCHOOL OF HEALTH TECHNOLOGY OF PORTO; 3. MAIA INSTITUTE OF HIGHER EDUCATION, PORTUGAL

**Background** In Portugal, there are several physical activity (PA) programmes for elderly people developed by the local government. The importance of these programmes has been increasing since the evidence has shown that this type of health promotion interventions may reduce the deleterious effects of the ageing process. However, no study has already identified the general characteristics of these programmes nor if they use any scheme to assess the quality of the service provided. A widely-used scheme is the EFQM Excellence Model, which will be in the core of our present work. Thus, the main aims of this preliminary study were 1) to identify the general characteristics of the PA programmes developed by the Portuguese Local Public Administration 2) to determine the extent of implementation of quality initiatives in these programmes. **Methods** Data were collected by an on-line questionnaire sent to all Continental Municipalities ( $n=278$ ). Categorical data were expressed as absolute counts and percentages. Continuous data were expressed as the mean and SD. An open-ended question was analysed using qualitative content analysis with QSR NVivo software. Associations between categorical variables were tested by the use of contingency tables and the calculation of chi-square tests. Significance level was set at  $p \leq 0.05$ . **Results** Results showed: i) a total of 125 PA programmes were identified in the 18 districts of the Portugal mainland; ii) the main goal of the majority (95.2%) was the participants' health promotion; iii) different characteristics of the programmes were found according to different regions of the country; iv) certain characteristics of the programmes were associated to the existence of other features; v) only one PA programme developed quality initiatives. **Conclusions:** Although there are many PA programmes for elderly people spread throughout the country, aiming at improving the health of participants, the overwhelming majority does not adopt quality control initiatives. Considering that the quality of a service increases customer satisfaction, the continuous quality improvement of the PA programmes for elderly people should therefore be implemented since they can be useful and critical for elderly satisfaction and adherence.

### RECREATION WITHIN THE PROCESS OF INDUSTRIAL REVOLUTION

ULKER, E.

SELÇUK UNIVERSITY

**Introduction** Nowadays, we see that leisure time is evaluated as the benediction of development especially in the industrialized and developing countries within the process of development in understanding of leisure time. Since the beginning of process of Industrial Revolution, there have been occurred many problems such as urban population, working hours and child employment and these problems are important for leisure time and recreation concepts. When existence of these kinds of problems around the world is considered, it is required to examine and investigate recreation concept within the process of industrial revolution. Britain transformed its traditional economy and society to modern industrial condition between the years of 1750- 1830 and this transformation affected leisure time concept significantly. People left their villages and came to the conditions in which there were no sufficient time and place for resting. It was thought that people's working productively would provide individual and communal reconstruction and more than 70 hours per week were allocated for working. Male and female workers started working in similar conditions and works and they tended to re-creative activities in order to rescue from being tired and boringness of their working environment. In the later 1800's, America began realizing its responsibilities in local government recreation services; park zones and playgrounds were opened, schools released their facilities to the public and recreation unities were organized. The Playground Association of America was built and Play Congress was organized. And then European Countries, also, realized recreation need, for example: The Copenhagen Playground Association was organized. Park zones, open areas and swimming pools were made usable incrementally for community health and physical recreation in Britain. **Conclusion** With Industrial Revolution, an individual, who is physically active in his life in which he makes his living by working in lands (agricultural worker), separated from his lands, and became inactive; children and adults did not find comfort in city life as they found in rural

areas; its deficiency was needed. In that way, leisure time concept arose and people filled their leisure times with recreation activities. Valuing leisure time gained importance on the positive effects registered in working life by people. In the later 1800's, local governments began realizing their responsibilities in recreation services and organizing recreation unities and they arranged some places such as park zones and playgrounds. The Playground Association of America was found, European countries became conscious, institutions were reconstructed for recreation, organizations were made and the ability to do the necessary for recreation gained importance, working conditions were regularised and developed. #### IMMUNE RESPONSE AND SERUM HEAT SHOCK PROTEINS CONCENTRATION IN YOUNG TENNIS PLAYERS AFTER THE WHOLE TOURNAMENT SEASON

ZIEMANN, E.1, KASPERSKA, A.2, ZEMBROŃ-LACNY, A.2, ANTOSIEWICZ, J.1, LASKOWSKI, R.3

1 WARSAW SCHOOL OF SOCIAL SCIENCES AND HUMANITIES, Sopot, Poland, 2 ACADEMY OF PHYSICAL EDUCATION, FACULTY OF PHYSICAL CULTURE GORZÓW WLKP, Poland, 3 ACADEMY OF PHYSICAL EDUCATION AND SPORT GDANSK

**Introduction** There are a lot of evidences that exaggerate sport activity may lead to systemic inflammation. Increase blood pro-inflammatory cytokines has been observed in basketball players sportsmen after play-off tournament (Zembroń-Lacny et al 2010) and among rowers after 8 weeks prior to the 2007 Rowing World Championships (Main et al, 2010). Still, these researches refer mostly to adult athletes. Only a small number of investigations focus on the relation between immune response and regular training with extensive exercise workload in adolescent athletes (Deguchi et al 1988). The main purpose of this study was to investigate if long lasting tournament season in young tennis players causes low grade systemic inflammation and induced adequate increase in anti-inflammatory heat shock proteins. **Methods** Well-trained 16 young tennis players ( $15 \pm 0.9$  years old, singles national ranking 3-39) took part in this study. The study was performed after tournament season, three days before a tennis-camp in autumn-winter period. It was approved by the hosting university's Research Ethics Board. Serum inflammatory cytokines (IL-1 $\beta$ , TNF $\alpha$ , IL-6, IL-10) and Hsp27, Hsp70 were measured by commercially Elisa kits. Results Pro-inflammatory cytokines have been shown to be elevated in most of the athletes compared to normal values reported for athletes (TNF $\alpha$  4.05 pg . ml<sup>-1</sup>, IL-1 $\beta$  2.9 pg . ml<sup>-1</sup>). However, the hydrogen peroxide and lipid peroxides did not point out on oxidative stress. The average values of Hsp27 and Hsp70 were 300 pg . ml<sup>-1</sup> and 4.7 ng . ml<sup>-1</sup> respectively. **Discussion** Our findings indicate that whole tournament season in young tennis players triggered elevated pro-inflammatory cytokine concentration response. Supposedly, this reaction could have resulted from the insufficient production of Hsp27. #### IMMUNE RESPONSE TO EXERCISE IN THE HEAT FOLLOWING A PERIOD OF PROBIOTICS SUPPLEMENTATION

SHING, C.M.1, PEAKE, J.M.2, BRISKEY, D.L.2, LIM, F.3, VITETTA, L.2

1: UTAS (TASMANIA, AUSTRALIA), 2: UQ (BRISBANE, AUSTRALIA), 3: DSO NATIONAL LABORATORIES, SINGAPORE

**Introduction** Intense exercise training and/or heat stress lead to various immune and gastrointestinal disturbances. These disturbances in immune function and gastrointestinal barrier have been associated with increases in systemic lipopolysaccharide (LPS) (Lim et al, 2009; Selkirk et al, 2008). In view of the purported benefits of probiotics on gastrointestinal immune function, this study investigated the influence of probiotics supplementation on gastrointestinal permeability and systemic inflammation when exercising in the heat. **Methods** Twelve trained, male runners (Height:  $178 \pm 7$  cm, Body Mass:  $72.6 \pm 7.6$ , VO<sub>2</sub>max:  $62.9 \pm 6.8$  kg/ml/min, Age:  $29 \pm 7$  years) completed the double-blind, placebo controlled, randomised cross-over trial. Runners exercised to fatigue at a speed corresponding to 80% ventilatory threshold in 35°C, 40% humidity. This treadmill run was repeated under the same conditions following four weeks of supplementation with either probiotics or a placebo. Following a three week washout period runners completed the cross over. Five grams each of lactulose and rhamnose were administered prior to each run and urine collected for a five hour period to assess gastrointestinal permeability. Venous blood samples were collected pre-, post-, and 1hr post-exercise for the determination of full blood counts, LPS and cytokines. Core temperature was monitored during each run via an ingested temperature sensor telemetry system. **Results** Four weeks of supplementation with probiotics significantly reduced lactulose-to-rhamnose ratio following running in the heat (pre-exercise:  $0.030 \pm 0.018$ , post-exercise:  $0.018 \pm 0.008$ ), when compared to a placebo (pre-exercise:  $0.022 \pm 0.008$ , post-exercise:  $0.021 \pm 0.009$ ) ( $p=0.032$ ). Probiotics supplementation was associated with a reduction in one hour post-exercise IL-10 ( $p=0.038$ ) and IL-6 concentration ( $p<0.005$ ). There was a significant effect of trial (pre- to post-supplementation) x group for LPS concentration ( $p=0.02$ ), with post-exercise values lower following probiotics supplementation. Area under the curve for core temperature was not significantly different between groups ( $p=0.34$ ). **Discussion** Probiotics supplementation reduces gastrointestinal permeability when running in the heat, which may influence circulating inflammatory cytokines and LPS concentration. #### EFFECTS OF HIGH-INTENSITY EXERCISE ON SKIN SURFACE SECRETORY IMMUNOGLOBULIN A AND RESIDENT BACTERIA

EDA, N., SHIMIZU, K., SUZUKI, S., NOKURA, K., TANABE, Y., LEE, E., AKAMA, T.

WASEDA UNIVERSITY

**Introduction** For athletes, preventing infectious disease on skin is important. It was reported that the number of staphylococcus aureus on athletes' skin increased after games and training (Kukidome et al., 2000 ; Daniel et al., 1989). Secretory immunoglobulin A (SigA) is secreted on skin surface with sweat, and works as the first line of defense against pathogenic microbial invasion. Therefore, SigA on skin

surface is useful to estimate athletes' skin condition. The aim of this study was to determine the effects of high-intensity endurance exercise on skin immunity by estimating SIgA concentration. Methods Seven healthy adult males participated in this study. Each of them performed bicycle exercise at 75%HRmax for 60 min. On middle of chest and medial side of the forearm, SIgA was obtained from 1 ml extraction liquids stirred with the microtube homogenizer in the polypropylene tube for 60 sec, and staphylococci were harvested by pressed agar-based media against the skin surface. Results SIgA concentration on medial side of the forearm was significantly lower at B2 ( $p < 0.05$ ) and B3 ( $p < 0.05$ ) than that at B1, and that on middle of chest at B1 tended to be higher compared with B2 ( $p=0.084$ ) and B3 ( $p=0.075$ ). The number of staphylococci was significantly higher at B2 than that at B1 ( $p < 0.01$ ) and B4 ( $p < 0.01$ ) on medial side of the forearm. Discussion SIgA concentration on skin surface significantly decreased after exercise. It is inferred the amount of sweating increased during exercise, so SIgA was flushed out with sweat and significantly reduced. The number of staphylococci on medial side of the forearm significantly increased after exercise. Staphylococci are resident bacteria on skin surface. It is possible that staphylococci leave through the pores with sweat during exercise. In this study, on medial side of the forearm, SIgA concentration significantly decreased and the number of staphylococci increased between B1 and B2. These results agree with previous studies that atopic dermatitis patients were lower SIgA concentration and more numbers of staphylococci, and susceptible to skin infections (Imayama et al., 1994; Nilsson et al., 1992). In summary, we conclude that high-intensity endurance exercise might depress immune function and enhance infectious risk on skin surface. References Kukidome T, Sato M, Yoshimura K, Tagami K. Introduction: Reductions in salivary secretory immunoglobulin A (SIgA) are related to incidence of upper respiratory tract infections (Kon et al., 2010). High-load exercise training causes a decline in salivary SIgA. The purpose of this study was to investigate the effect of tapering after high-load training on salivary SIgA in elite speed skaters. Methods: The subjects were 8 speed skaters who participated in the Japan single distances speed skating championships. Training load, saliva flow rate, salivary SIgA concentration, salivary SIgA secretion rate, and subjective fatigue were measured during high-load training and tapering periods. SIgA concentrations were measured by enzyme immunoassay, and SIgA secretion rate was calculated. Training load was quantified using Training Impulse (TRIMPs). A visual analogue scale was used to subjectively assess fatigue. Results: The training load recorded for tapering period was significantly lower than that recorded for high-load training period ( $p < 0.01$ ). There was no significant difference in the saliva flow rate and SIgA concentration. The SIgA secretion rate recorded for tapering period was significantly higher than that recorded for high-load training period ( $p < 0.05$ ). The subjective fatigue recorded for tapering period was significantly lower than that recorded for high-load training period ( $p < 0.05$ ). Discussion: It is reported that salivary SIgA is influenced by exercise training load. Akimoto et al. (1998) showed that salivary SIgA decreased after high-load exercise training. On the other hand, moderate exercise training increased salivary SIgA (Klentrou et al., 2002). Thus, salivary SIgA of elite speed skaters might be improved by the reduction in training load in this study. In summary, we concluded that tapering improves salivary SIgA secretion rate in elite speed skaters. Tapering before competition may be useful not only for the reduction of accumulated fatigue but also for the improvement in mucosal immune function (salivary SIgA) of elite athletes. ### EXERCISE-RELATED CHANGES IN THE ACTIVITY OF SALIVARY IMMUNOGLOBULIN A AND MELATONIN: A PILOT STUDY FOR DEPRESSION PATIENTS

ISHIWATA, T., KATO, H., ENDO, S., YASUMATSU, M., KANO, H., NIGORIKAWA, T., SUGIURA, K., MATSUO, T., OISHI, K., MATSUYAMA, M.

*RIKKYO UNIVERSITY*

Introduction According to the Ministry of Health, Labour and Welfare, in Japan, the number of patients with mood disorders, including depression, doubled from 440,000 in 1999 to over 1,000,000 in 2008. It is well known that exercise is indispensable to effective health management. We believe that supports based on objective indicators along with exercise programs are beneficial for people with mood disorders. Thus, we aim to devise a simple index that is objectively appreciable of the physical condition of such patients. In an attempt to do so, we performed a pilot study for patients with depression by studying the physiologically active substances—immunoglobulin A (IgA) and melatonin (Mel)—in the saliva. Methods First, we observed the effects of daily events on the salivary activity of IgA and Mel in 10 healthy male university students. The activity of IgA and Mel were measured by ELISA and HPLC, respectively. We collected each sample 4 times a day (7:00, 12:00, 18:00, and 24:00) for 5 consecutive days. The daily events, i.e., exercise, work, sleep, and mealtime, were recorded simultaneously. Next, we determined the effects of an acute exercise on the activity of IgA and Mel in 20 healthy male university students. These students played football, basketball, table tennis, or recreational sports; the activity of IgA and Mel were measured before and after each exercise. Results In many individuals, the IgA concentration was higher in the morning than in the afternoon. However, in some subjects, different trends in IgA levels were observed. These individualistic differences were lifestyle-dependent, as were the differences in the concentrations of Mel. It was observed that the changes in IgA concentrations before and after the exercise differed according to the nature of the exercise. Discussion The changes in the activity of IgA and Mel depended on the lifestyle of the subject and/or the nature of the exercise performed. The patterns of change might be related to the individual's physical condition. It was suggested that exercise affects the physical condition and biological rhythm of individuals. Thus, the salivary activity of IgA and Mel can be considered as candidates for simple physiological indexes for the physical condition of depression patients.

### PP-PM08 Training and Testing: Strength and Flexibility

#### TESTSTATISTICAL EVALUATION OF THE DEUTSCHE MOTORIK-TEST 6-18

ELLINGER, B., FRÖHLICH, M., KOCH, M.  
BIELEFELD UNIVERSITY

Ellinger, B.1, Fröhlich, M.2, Koch, M.2 1: Bielefeld University (Bielefeld, Germany), 2: Saarland University (Saarbrücken, Germany) Introduction The Deutsche Motorik-Test 6-18 (DMT 6-18) is a test series to analyze the motor performance of male and female students aged between 6-18 years. The DMT 6-18 includes eight test dimensions for testing motor performance. These dimensions cover all of the motor abilities – endurance, strength, speed, coordination and flexibility (Bös et al., 2009). One of these dimensions determining coordination under time pressure is the so-called 'Seitliches Hin- und Herspringen' (SHH; means jumping bidirectionally for 15 seconds). The purpose of the study was to analyze the reliability of the chosen method by observer objectivity. Methods 15 male and 15 female students at an average age of  $12.97 \pm 0.31$  years were tested with DMT 6-18. The SHH was observed via video analysis and by two independent, trained observers to gain more objective results. The duration between the initial testing and the terminal testing was 8 weeks. The results of the video analysis and observer analysis were compared. The value of the coefficient of correlation was used for interpreting the reliability of SHH. Additionally, a test-retest method (video and observer data) was used for obtaining coefficients of reliability. Results The coefficient of correlation between observer and video analysis shows a highly significant correlation ( $r=0.91$ ;  $r^2=0.82$ ;  $p<0.05$ ). The mean difference between observer ( $43.38 \pm 8.32$ ) and video analysis ( $39.80 \pm 9.99$ ) was 3.6 errors. The test-retest reliability for observer data was  $r=0.81$  ( $r^2=0.65$ ), and for video data  $r=0.82$  ( $r^2=0.68$ ) (all  $p<0.05$ ). The mean difference for observer data was 4.13 errors, and for video data 1.86 errors. Discussion The results of the video analysis and independent observation show that the reliability for the test dimension SHH is assured. Only 18 % of variance is not clear. In total, the test-retest reliability is slightly lower, but still has a very good value. In all, reproducibility of the SHH result exists. Thus, independent testers can illustrate coordination under time pressure to a sufficient degree. If a real value on the performance in SHH is the goal, technical support, such as videometrics, is recommended. However, if multiple persons are examined under time pressure, video analysis is too complex a means. #### THE RELIABILITY OF ISOKINETIC KNEE STRENGTH TESTING IN PHYSICALLY ACTIVE STUDENTS

STREJCOVA, B., BALAS, J.  
FACULTY OF PHYSICAL EDUCATION AND SPORT

Introduction Isokinetic strength is characterized by exercise with an accommodating resistance and fixed speed. Isokinetic dynamometry has been used in clinical and sport practice (Brown, 2000). In clinical practice, the isokinetic dynamometer has been used as part of the rehabilitation programme after muscle disfunction, in assessing disorders such as rotator cuff overuse, anterior instability or neurological pathology. In sport practice, isokinetic measurement has served to assess the stage of the training process in volleyball, tennis, swimming and baseball athletes (Dauty et al., 2003). The aim of the study was to compare the reliability of isokinetic knee strength testing in physical education students. Methods Thirteen physical education students (8 males, 5 females) were measured on the Cybex Humac Norm dynamometer. The concentric strength was tested during the right and left knee extension and flexion at angular velocities  $60^\circ/\text{s}$  (5 rep.) and  $180^\circ/\text{s}$  (15 rep.). The reliability was calculated using the ICC (3,k) (Shrout & Fleiss, 1979) for the right and left knee. The values of ICC were assessed for peak torque, total work and average power in extension and flexion of knee concentric muscle strength. Results The intraclass correlation coefficients (ICC) ranged between 0.92-0.95 for flexion and 0.91-0.96 for extension at angular velocity  $60^\circ/\text{s}$  and 0.88-0.94 and 0.95-0.97 at  $180^\circ/\text{s}$ . The results confirmed high reliability for the specific knee isokinetic strength testing. Discussion The value of reliability has been reviewed by many authors (Dauty et al., 2003; Shrout & Fleiss, 1979), suggesting that ICC values over 0.90 indicated excellent reproducibility, whereas scores of between 0.75-0.90 were acceptable. Our results of ICC indicated excellent values of reliability in majority of cases in physically active students. References Brown, L. E. (2000). Isokinetics in human performance. L. (1979). Psychological Bulletin, 36, 420-428.

#### FAMILIARIZATION SESSION INCREASES INTRA SESSION RELIABILITY IN JUMP EVALUATION

CARVALHO, L.A.C.M.1, CANÇADO, G.H.C.P.1, ANDRADE, A.G.P.1, CHAGAS, M.H.1, MENZEL, H.J.K.1  
1 UNIVERSIDADE FEDERAL DE MINAS GERAIS

INTRODUCTION Good values of intra session reliability are important to identify significant differences in the outcome measures of transversal experimental studies (Hopkins, 2000; Weir, 2005). Familiarization session is necessary to increase stability on a task (Weir, 2005). Therefore, the aim of this study was to identify the effect of a familiarization session on variables of maximum effort drop jump task. METHODS Through the impulse method with one force plate the free falling displacement of the centre of gravity (FFDCG), the contact time (CT) and the jump height (JH) were determined. The subjects were 22 young physical active males (Age 21.4 years SD 2.2) (BW 74 kg SD 9.2) (BH 1.72m SD 0.11) (BMI 23.6 SD 2.1). Jumps were performed in a random order. Two perfect jumps were recorded from each of four drop platforms (20, 30, 40, 50 cm) with 3 minutes rest period between jumps. Before each jump the following command was given systematically: "with your hands on your hips, try to fall from the height that you were in, using the minimum contact time and maximum jump effort". These procedures were conducted twice with a two day interval. For each variable the typical error ( $TE = DP / \sqrt{2}$ ) and the typical percentage error ( $TE\% = TE \cdot 100 / \text{mean}$ ) were calculated. RESULTS The increase in the intra session reliability, expressed as TE%, were 1.2% (SD:0.8), 4.6% (SD:2.8), 2.8% (SD:2.5), for FFDCG, TC e JH, respectively. Moreover, a decreasing in the number of tries to get the two valid jumps from the 20, 30 and 50 cm drop platforms ( $p = 0.05$ ) was observed. DISCUSSION The decrease in the values of TE and TE% for all variables as well as the decrease in the number of tries from the first to the second day of evaluation demonstrate a positive learning effect (Schmidt & Lee, 2005), more specifically increasing the stability of the jump technique due to the familiarization session (first section) (Sale, 1991). **RELIABILITY OF THREE CLINICAL TESTS MEASURING CORE AND WHOLE-BODY STABILITY**

BORGHUIS, A.J.

UNIVERSITY MEDICAL CENTER GRONINGEN

**RELIABILITY OF THREE CLINICAL TESTS MEASURING CORE AND WHOLE-BODY STABILITY** Borghuis, A.J.<sup>1</sup>, Lemmink, K.A.P.M.<sup>1,2</sup>, Hof, A.L.<sup>1</sup>. 1: Center for Human Movement Sciences, University Medical Center Groningen, University of Groningen, Groningen, the Netherlands 2: School of Sports Studies, Hanze University of Applied Sciences, Groningen, the Netherlands **Introduction** To study the effect of neuromuscular training programs on improving core stability, a valid and reliable measurement method should be developed that is based on a widely accepted definition of the concept of core stability. The body's core is defined as the lumbopelvic complex with all its surrounding tissues, like muscles, tendons and ligaments. Postural stability is a dynamic state, characterized by efficient equilibrium recovery and resistance to perturbations. On the basis of these concepts, core stability is defined as the ability of the neuromusculoskeletal system to maintain or resume an upright position of the trunk in labile situations or in the presence of disturbances. The purpose of the present study was to introduce a graduated sitting balance test and a seated perturbation test as valid measures of core stability and robustness, respectively. Furthermore, test-retest reliability of both tests and of an adapted version of a previously developed standing balance test (the narrow ridge balance test developed by Curtze et al., 2010) was investigated, together with the relationships between the different test results. **Methods** Thirty healthy university students performed the three tests two times with a period of one week in between. Intra-class correlation coefficient (ICC), standard error of measurement (SEM) and minimal detectable change (MDC) were calculated to indicate reliability and responsiveness of the test results and correlations were calculated to relate the different test results to each other. **Results** A systematic bias was found for the balance scores obtained with the graduated narrow ridge test and the graduated sitting balance test and for some measures obtained with the seated perturbation test, indicating a learning effect. ICC values of all test results varied between 0.55 and 0.94. Lateral standing balance and sitting balance scores correlated significantly with lateral Time To Stabilization (TTS) in the seated perturbation test, with correlations ranging between -0.46 and -0.63. **Discussion** Test-retest reliability of the three tests investigated was moderate to substantial, with some measures showing almost perfect reliability. Results indicated that adequate reactive neuromuscular trunk control plays a role in stabilizing both standing and seated posture in the frontal plane. Future research should focus on refining these measurement methods to eventually use them in assessing the effect of neuromuscular interventions on improving core and whole-body stability. **References** Curtze C, Postema K, Akkermans HW, Otten B, Hof AL. (2010). Gait Posture, 32(4), 627-31.

**FIELD TESTS OF FLEXIBILITY OF THE LOWER EXTREMITY: THE SENSITIVITY ANALYSIS**

PAZIN, N., BERJAN, B., BOZIC, P.

FACULTY OF SPORT AND PHYSICAL EDUCATION

**FIELD TESTS OF FLEXIBILITY OF THE LOWER EXTREMITY: THE SENSITIVITY ANALYSIS** Pazin, N.<sup>1</sup>, Berjan, B.<sup>2</sup>, Bozic, P.<sup>2</sup> 1: Faculty of Sport and Physical Education (Belgrade, Serbia), 2: Serbian Institute of Sport (Belgrade, Serbia) **Introduction** The field test of flexibility has been commonly used to identify performance limiting factors, to assess the intrinsic risk factors of sport injuries, to monitor the effects of training and rehabilitation programs, to compare various individuals and groups, as well as for the talent selection purposes. However, there is apparent lack of data regarding the sensitivity of field tests of flexibility of the lower extremity. Therefore, the purpose of this study was to evaluate the standard field tests of flexibility of the lower extremity through their sensitivity with respect to different training history. **Methods** Sixty-seven healthy male subjects with distinctive training histories were divided into 4 groups: soccer players (n = 21), basketball players (n = 18), karate competitors (n = 12), and physically active individuals (n = 16). Following a familiarization session, the subjects were tested by means of standard devices (i.e., kinantropometry, ruler tape, and protractor) on the following flexibility tests: Leg Raise in a Supine Position (LRSP), Hip Abduction Test (HAT), Single-Legged Knee Bend (SLKB), Sideward Leg Splits (SdLS), Sit and Reach (SR), Sideways Leg Splits (SsLS) and Lengthwise Leg Splits (LLS). **Results** A one-way MANOVA revealed significant main effects of group (Wilks'  $\lambda = 0.363$ ;  $F(21, 164) = 3.307$ ,  $p < 0.001$ ) where the post hoc ANOVAs generally suggested a high sensitivity (particularly in SdLS), except for SR and SLKB that proved to be insensitive. In addition, Tukey post hoc test revealed the highest level of flexibility in karate competitors, as compared to other participant groups. The effect size of difference (calculated as partial eta squared:  $\eta^2$ ) for all tests were relatively high ( $\eta^2 = 0.27 - 0.43$ ). **Discussion and conclusions** In general, the findings of the present study suggest that the simple and effective field tests of flexibility of lower extremity based on using both a standardized and inexpensive equipment could be sensitive with respect to different training background. We could particularly recommend using SdLS test rather than the most frequently used SR test, not only because of its exceptionally high sensitivity, but also because of advantageous methodological (i.e., high reliability and factorial validity; Bozic et al., 2010) and anatomical properties (Alter, 1996). **References** Alter MJ. (1996). Science of Flexibility. Champaign, IL: Human Kinetics. Bozic P, Pazin N, Berjan B, Planic N, Cuk I. (2010). **EFFECT OF A HEAVY RESISTANCE EXERCISE WARM-UP ON PERFORMANCE DURING A RUGBY-SPECIFIC EXERCISE PROTOCOL**

STOKES, K., OWEN, W., ROBERTS, S., TREWARTHA, G.

UNIVERSITY OF BATH

Rugby union is characterised by phases of intermittent, low intensity activity combined with short periods of maximal effort during which players are required to produce high forces against external loads (e.g. rucking, mauling and scrummaging). The purpose of this study was to investigate the effects of a heavy resistance exercise "post-activation potentiating" (PAP) warm-up on performance during one 21 min block of the Bath University Rugby Shuttle Test (BURST) (Roberts et al., 2010), a rugby union match-simulation protocol. Twelve male rugby players (mean (SD); age, 20 (2) years; body mass, 82.4 (11.5) kg) performed two trials in a random order at least one week apart. In each trial, prior to the 21-min block of the BURST, participants performed a warm-up of jogging, dynamic stretching, high-intensity running and then either three sets of three: (i) body-weight squats (control), or (ii) heavy squats at 80, 85 and 90% of one repetition maximum (PAP). Participants then recovered for 8 minutes before beginning the BURST. A 21-min block of the BURST comprised four identical 5-min cycles including 20-m shuttles of walking, jogging and cruising, interspersed with simulated rucks, scrums and mauls. In the last minute of every 5-min cycle, participants carried out a timed Performance Test comprising one 9-m tackle bag carry, one Assassin push (4-m horizontal leg drive of a 180-kg cart up an incline of 4° (RJF Design, Surrey, UK)) and an agility sprint with a ball. After 25 s of recovery, a 15-m sprint was performed. Outcome measures were the Performance Test time, Assassin push time and 15-m sprint time. Two-way repeated measures ANOVA showed that 15-m sprint time did not change significantly over time and was not significantly different be-

tween trials at any timepoint (control, 2.55 (0.12) s vs. PAP, 2.55 (0.11) s; time main effect,  $P = .30$ ; trial main effect,  $P = .98$ ; interaction effect,  $P = .56$ ). Assassin push performance did not change over time (time main effect,  $P = .07$ ), but was significantly faster in the PAP trial (control, 1.17 (0.12) s vs. PAP, 1.15 (0.12) s; trial main effect,  $P = .02$ ). The interaction effect was not significant ( $P = .70$ ). Performance Test time did not change significantly over time and was not significantly different between trials at any timepoint (control, 16.76 (0.92) s vs. PAP, 16.78 (1.05) s; time main effect,  $P = .23$ ; trial main effect,  $P = .95$ ; interaction effect,  $P = .76$ ). In conclusion, a heavy resistance exercise "potentiating" warm-up did not improve 15-m sprint or Performance Test time, but improved horizontal push performance. This finding may have benefits for rugby forwards during the early part of a match. Roberts, S P, Stokes, K A, Weston, L, Trewartha G. (2010). *Int J Sports Physiol Perform*, 5 (1), 64-74.

## PREDICTION OF OPTIMAL HQ RATIO IN TEST OF CONSECUTIVE MAXIMAL CONTRACTIONS

KNEZEVIC, O., MIRKOV, D.M.

*FACULTY OF SPORT AND PHYSICAL EDUCATION*

**PREDICTION OF OPTIMAL HQ RATIO IN TEST OF CONSECUTIVE MAXIMAL CONTRACTIONS** Knezevic, O., Mirkov, D. Faculty of Sport and Physical Education, University of Belgrade, Serbia **INTRODUCTION** The hamstrings-to-quadriceps (HQ) ratio has received a lot of attention in rehabilitation monitoring (Suzovic et al., 2008). Although mostly assessed from standard strength tests measures, due to its simplicity, cost-effectiveness, and high test-retest reliability (Suzovic et al., 2008, Mirkov et al., 2009), the recently proposed test of neuromuscular function based on consecutive maximal contractions (CMC) could be a promising one. Since Q and H exert maximal strength at different knee angles (KA) while CMC requires them to be measured in a single one, the question remains which KA could provide the most appropriate HQ ratio. The aim of our study was to determine the "optimum" KA for CMC testing as well as to compare the obtained HQ ratio with the HQ ratios of healthy subjects and the athletes with recent ACL reconstruction. **METHODS** The quadriceps and hamstrings peak torque (PT) of dominant leg of 20 healthy male university students was assessed at KA of 100°, 120°, 140° and 160° by means of CMC test using Kin-Com isokinetic dynamometer. Subjects' mean PT for each individual angle and muscle was normalized and interpolated with 2nd order polynomial function to obtain the "optimum" KA and HQ ratio. To evaluate this HQ ratio, 17 students and 8 athletes 4 months following their surgery were tested at the determined KA, and HQ ratios of dominant and non-dominant dominant (or, alternatively non-dominant and injured leg) were calculated and compared with the "optimum" HQ ratio. **RESULTS** The results revealed optimum KA of 135° while the HQ ratio of 0.43(0.09). The HQ ratios obtained at the KA at 135° of dominant and non-dominant leg were (data as mean (SD) 0.47 (0.06) and 0.44 (0.12), and of healthy and injured leg 0.50 (0.09) and 0.84 (0.22), respectively. There were no differences between "optimum" and HQ ratios of the dominant, non-dominant and healthy leg, respectively. Significant differences were found between optimum and HQ ratio of the injured leg ( $p < 0.01$ ) as well as between healthy and injured leg ( $p < 0.01$ ). **DISCUSSION** The optimum angle could be between 120° and 150° interval, which provides maximum strength of Q and H. Therefore, PT obtained from CMC could assess muscles' ability to exert maximum sustained contraction despite being both transient and relatively low (Suzovic et al., 2008). Taking also into account findings (Suzovic et al., 2008, Mirkov et al., 2009) these results suggest that CMC test performed at the optimum angle and corresponding HQ values could provide a standardized procedure for monitoring recovery following knee injuries. **REFERENCES** [1] Suzovic D et al. (2008). *J Hum Kin*, 20, 51-67. [2] Mirkov D et al. (2009). 14th Ann. ## ISOKINETIC PROFILE OF KNEE STRENGTH IN HEALTHY UNTRAINED MALES AND FEMALES

PRESHELKOV, R.

*SOUTH-WEST UNIVERSITY, BULGARIA BLAGOEVGRAD*

**ISOKINETIC PROFILE OF KNEE STRENGTH IN HEALTHY UNTRAINED MALES AND FEMALES** Preshelkov, R. South-West University, Faculty of Public Health and Sports (Blagoevgrad, Bulgaria) **Introduction** Isokinetic evaluations can be used as an objective strength measure in clinical research and sports environments. The aim of the present study was: - to assess the isokinetic strength in different angular velocities of knee extensors and flexors in healthy untrained; and - to compare the main indices, including flexor/extensor or left/right ratios, between males and females. **Methods** Twelve male (19.8±0.3 years; 178.9±2.0 cm; 73.8±3.2 kg; BMI - 23.0±0.7) and 8 female (19.8±0.5 years; 169.5±1.9 cm; 59.5±2.2 kg; BMI - 20.7±0.5) healthy, right legged, untrained volunteers participated. To evaluate subject's maximal knee flexion/extension muscle strength, an isokinetic dynamometer (Biodex System 4 Pro) was used. The isokinetic concentric regime of loading at 3 angular velocities - 60, 180 and 300 degrees with 5, 10 and 15 repetitions, respectively, were included in the experimental protocol. **Results** The values (mean±SEM) of the isokinetic (velocity 60 degrees) extension peak torque 234±9 Nm, total work 1274±48 J and average power 150±9 W in males were significantly ( $p < 0.01$ ) higher as compared with those of females (146±7, 990±72 and 138±9, respectively). The decrease of knee flexor/extensor ratios in comparison with the normal limits (Dvir, 1995) in female volunteers was by 32, 35 and 31 % in angular velocities of 60, 180 and 300 degrees for both right and left legs, while that in males was by 18, 20 and 17 % respectively. There were no significant differences in the strength indices between the left and right knee in both genders. The correlation between the peak torque in all angular velocities and lean body mass was found ( $r = 0.8$ ,  $p < 0.05$ ) in males. **Discussion** The experimental design allows evaluation of the changes in the peak torque of knee extensor or flexor group at different joint angular velocities. The gender differences in the strength indices were established, although the influence of sex on skeletal muscle strength and its anthropometric reasons, is well documented (Miller et al., 1993; Doherty, 2001). The more pronounced decrease of the hamstring to quadriceps ratios in all angular velocities in females found in this study is in accordance with the data of Hewett et al., (2008) and Holm and Vollestad (2008). These findings give causes for application of the kinesitherapeutic programs to improve dynamic control of the knee by emphasizing hamstring strengthening. **References** Doherty TJ (2001). *Clin Nutr Metab Care*, 4(6), 503-508. ### ISOMETRIC STRENGTH AND STEADINESS OF M. QUADRICEPS FEMORIS FOLLOWING REGULAR LEVEL AND DOWNHILL TREADMILL WALKING AT SELF-SELECTED SPEED IN OLDER ADULTS

GAULT, M., CLEMENTS, R.E., WILLEMS, M.E.T.

UNIVERSITY CAMPUS SUFFOLK

ISOMETRIC STRENGTH AND STEADINESS OF M. QUADRICEPS FEMORIS FOLLOWING REGULAR LEVEL AND DOWNHILL TREADMILL WALKING AT SELF-SELECTED SPEED IN OLDER ADULTS Gault, ML1, Clements, RE.2, Willems, MET.2 1: University Campus Suffolk (Ipswich, UK), 2: University of Chichester (Chichester, UK) Introduction Older adults experience a decline in muscle strength and steadiness, decreasing quality of life and increasing risk for falls. Adaptations by eccentric endurance exercise (i.e. downhill walking) may preserve muscle strength and steadiness in older adults. The aim of the current study was to determine in older adults the effects of concentric (level treadmill walking) and eccentric endurance exercise (downhill treadmill walking) on maximal and submaximal sustained isometric contractions of m.quadriceps femoris (QF) with electromyographic recordings of the m.vastus lateralis (VL). Methods 18 healthy older adults (age:  $67 \pm 4$ , body mass:  $75 \pm 14$  kg) completed 12 weeks of level treadmill walking (LW, 0%,  $n=8$ ) or downhill treadmill walking (DW, -10%,  $n=10$ ) (30 min, 3 d•wk<sup>-1</sup>) at a self-selected walking speed (SSWS, re-adjusted in week 4 and 8). Maximal voluntary isometric force (MVIF) of QF and EMG of VL was measured at baseline, 4, 8 and 12 weeks. Steadiness of submaximal (5, 10 and 20%) isometric contractions (i.e. coefficient of variation of the force signal, CVI) of QF and EMG of VL was measured at baseline and 12 weeks. A two way repeated measures ANOVA with post-hoc pre-planned t-tests were used for data analysis ( $P < 0.05$ ). Results SSWS was similar for both groups and increased from  $1.18 \pm 0.11$  to  $1.53 \pm 0.09$  m•s<sup>-1</sup> (LW) and  $1.26 \pm 0.16$  to  $1.61 \pm 0.12$  m•s<sup>-1</sup> (DW) ( $P < 0.01$ ). Baseline MVIF of LW ( $340 \pm 112$  N) and DW ( $368 \pm 128$  N) increased equally by  $14 \pm 6$  and  $5 \pm 6$  % ( $P < 0.05$ ). Steadiness at 5% MVIF improved following 12 weeks of LW (baseline:  $0.04 \pm 0.01$ ; 12 wk:  $0.03 \pm 0.01$ ) and DW (baseline:  $0.04 \pm 0.02$ ; 12 wk:  $0.03 \pm 0.01$ ) ( $P < 0.05$ ). EMG root mean square of VL during MVIF increased by 38% ( $P < 0.05$ ) following 12 weeks but only in the level walking group. Discussion Regular level and downhill treadmill walking at a self-selected walking speed appears to be at an intensity to improve the ability to produce maximal voluntary isometric force of m.quadriceps femoris. For level walking, this may be explained by an increase in neural activation whereas muscle hypertrophy and coordination may explain the changes after regular downhill walking (Sipilä et al., 1996). The improvement in steadiness at 5% MVIF may be due to a change in discharge rate variability (Laidlaw et al., 2000). Improvements in the ability to produce maximal isometric force and isometric steadiness of submaximal isometric contractions by regular level and downhill treadmill walking at self-selected walking speed may reduce the risk for falls in older adults. ### VALIDITY AND RELIABILITY OF THE TENDO WEIGHT-LIFTING ANALYZER SYSTEM FOR MEASURING MOVEMENT VELOCITY.

GARNACHO CASTAÑO, M.V., JIMÉNEZ REYES, P., MUÑOZ GONZÁLEZ, A., DÍEZ RICO, C., MATÉ MUÑOZ, J.L.

UNIVERSIDAD ALFONSO X EL SABIO

Movement velocity in weight lifting exercises can be used as an indicator of relative load. The aim of this study was to evaluate the validity and reliability of movement velocity measurements obtained with the Tendo Weight-lifting Analyzer System (Trencin, Slovak Republic) by comparing them to those made with the T-Force Dynamic Measurement System (Ergotech, Murcia, Spain). For this purpose, three different exercises were carried out: bench press (BP), back squat (BS) and counter movement jump with load (CMJL). Forty subjects were asked to perform the aforementioned exercises and 1280 measurements of movement velocity (160 CMJL, 560 BS and 560 BP) were obtained in different sessions. Intraclass correlation coefficients (ICCs) for validity were very high (0.940-0.953). Test-retest reliability of the Tendo Analyzer System was also high, with ICCs ranging from 0.930 to 0.935. The Tendo Analyzer demonstrated to be a valuable and reliable system for measuring movement velocity in weight-lifting exercises.

### RELIABILITY OF TWO METHODS FOR ASSESSING MAXIMAL STRENGTH AND RATE OF FORCE DEVELOPMENT IN ROCK CLIMBERS

FANCHINI, M., SCHENA, F., BORTOLAN, L., PELLEGRINI, B., ROSPONI, A., IMPELLIZZERI, F.M.

CERISM, RESEARCH CENTRE FOR SPORT, MOUNTAIN AND HEALTH, UNIVERSITY OF VERONA, ROVERETO, ITALY

Introduction Maximal voluntary contraction (MVC) of the finger flexors has been suggested to be a determinant of rock climbing performance [1]. However, studies using different tools have found contradictory results. Handgrip (HG) measures have shown low discriminant ability, probably due to their lack of specificity. Specific climbing dynamometers (SCD) that more closely mimic the hold position could differentiate climbers from non-climbers (REF). Furthermore, the peak of rate force development (pRFD) has been suggested to be more appropriate than MVC [1] for evaluating neuromuscular characteristics of climbers. The apparent lower discriminant ability of generic strength measures may be due to lower reliability. The aim of this study was to compare the reliability of MVC and pRFD assessed using generic and specific dynamometers in climbers. Methods Fifteen male climbers (age  $32 \pm 7$  yrs; height  $175 \pm 5$  cm; weight  $69 \pm 5$  kg) participated in the study. They performed, in a randomized order, 6 contractions (3 for MVC and 3 for pRFD) of 4 s with 2 min rest using HG and SCD. After 24 hours they were re-tested. Reproducibility was expressed as Typical Error of the Measurement (TEM) and Intraclass Correlation Coefficient (ICC). Results The mean MVC in the 2 tests were  $6.6 \pm 1.4$  and  $6.4 \pm 1.3$  N/kg for HG and  $7.6 \pm 2.2$  and  $8.2 \pm 2.1$  N/kg for SCD, respectively. The mean pRFD in the 2 tests were  $42.7 \pm 11.7$  and  $43.6 \pm 11.2$  N/kg/s for HG and  $39.9 \pm 14.1$  and  $42.5 \pm 15.1$  N/kg/s for SCD, respectively. The TEMs for MVC and pRFD using HG were 4.3 % (90%CI, 3.3 to 6.3) and 9.1% (6.9 to 13.5%). The TEMs for MVC and pRFD using SCD were 6.7% (5.1 to 9.9%) and 15.8% (11.9 to 23.9%). The ICCs for MVC and pRFD using HG were 0.95 (0.88 to 0.98) and 0.92 (0.80 to 0.96). The ICCs for MVC and pRFD using SCD were 0.94 (0.85 to 0.97) and 0.83 (0.63 to 0.93). Discussion The HG and SCD showed similar reproducibility for MVC and pRFD, with MVC displaying lower TEM than pRFD. However, the acceptability of these TEM values (representing the "noise" of measurement) depends on the magnitude of change or differences (signal). For example since the decline induced by competition and simulation is higher for pRFD (-19%) than MVC (-6%)[2], the reliability of pRFD is better than MVC for detecting neuromuscular fatigue. In conclusion, this study did not show a superior method in terms of reproducibility. Nevertheless, since SCD displays higher face validity, specific measures should be preferred. References 1. ## THE EFFECT OF THE STRETCH BREAK PROGRAM ON FLEXIBILITY, STRENGTH, AND MUSCULOSKELETAL SYMPTOMS OF WORKERS

CURY-BOAVENTURA, M.F., MARTINS, P.F.O., ZICOLAU, E.A.A., VIEIRA, M., PITHON-CURI, T.C.

*INSTITUTE OF PHYSICAL ACTIVITY AND SPORTS, CRUZEIRO DO SUL UNIVERSITY*

**Introduction:** Repetitive movements and abnormal or prolonged posture, positions, or movements are commonly assumed during many work activities such as administrative or warehouse and cause cumulative trauma disorder (CTD). CTD is a collection of musculoskeletal disorders that are characterized by chronic discomfort, pain, and possibly functional impairment. **Objective:** The aim of this study was to test the effect of Stretch Break Program (SBP) on flexibility, strength and musculoskeletal symptoms of warehouse (WW) and administrative (AW) sector workers. **Methods:** 26 male subjects have participated in this study. We have applied International Physical Activity Questionnaire and Nordic Questionnaire of musculoskeletal symptoms and have evaluated flexibility and strength before and after 6 months of SBP implantation. **Results:** After a 6 month-period of SBP, we observed an improvement on flexibility values for upper limbs and total regions in WW and AW group. This gain may be directly related to reduction of complaint of numbness and pain in upper limbs. **Conclusion:** SBP increased strength and improved flexibility in the regions with the higher rate of lesion related to work contributing to the decrease of complaint due to musculoskeletal symptoms.

### PP-PM09 Training and Testing: Methods

#### RELIABILITY OF A HIGH-INTENSITY CYCLING CAPACITY TEST

SAUNDERS, B., SALE, C., HARRIS, R.C., SUNDERLAND, C.

*NOTTINGHAM TRENT UNIVERSITY*

**Introduction** The CCT110%, a cycling capacity test performed at 110% of maximum power output, was developed as a test lasting between 120 and 240 s and most likely limited by muscle acidosis (Hill et al., 2007). In subsequent studies (Sale et al., and Saunders et al., Unpublished data) we have used this test to examine the effects of dietary interventions designed to manipulate intra- and extra-cellular changes in pH during exercise. The aim of this investigation was to assess the reliability of the CCT110%. **Methods** Twenty seven males (age  $23 \pm 4$  y; height  $1.79 \pm 0.06$  m; body mass  $78.0 \pm 8.8$  kg) performed an incremental powermax cycle test to establish maximum power output. Participants were then required to complete two cycling capacity tests at 110% of maximum power output to determine time to exhaustion (TTE) and total work done (TWD). Participants performed the CCT110% in a fasted state with no alcohol or caffeine having been ingested during the previous 24 h. Trials were separated by 48 h. Blood pH, bicarbonate, base excess and lactate were determined pre-exercise, immediately post-exercise and 5 minutes post-exercise. Data were analysed using Bland-Altman analysis, intra-class correlations and repeated measures ANOVA. Data are presented as mean  $\pm$  1SD. **Results** TTE ( $P = 0.75$ ;  $134 \pm 20$  s and  $135 \pm 20$  s,  $d = 0.05$ ) and TWD ( $P = 0.97$ ;  $42.2 \pm 10.3$  kJ and  $42.2 \pm 9.8$  kJ,  $d = 0.00$ ) were not different between trials. The intra-class correlation between trials was  $r = 0.94$  for TTE and  $r = 0.97$  for TWD, with the coefficient of variation being 4.43% for TTE and 4.94% for TWD. Bland-Altman analysis indicates that the 95% limits of agreement ranged from -18.9 to +20.2 s for TTE and -6.94 to +6.99 kJ for TWD. There were no between trial differences in blood markers at any time point except immediately post-exercise pH ( $7.246 \pm 0.041$  Vs  $7.269 \pm 0.064$ ,  $P = 0.004$ ), although the actual difference was small (0.023). **Discussion** Performance measures were similar between trials, with times being within the expected range for this test. Exercise affected blood markers similarly in both trials. Although immediately post-exercise blood pH was significantly different between trials, the absolute differences are much smaller than those expected to be seen using nutritional interventions intended to alter extracellular pH changes during exercise. These findings suggest that the CCT110% is a reliable high-intensity cycling test. **References** Hill CA, Harris RC, Kim HJ, Harris BD, Sale C, Boobis LH, Kim CK, Wise JA. (2007). #### VALIDITY OF 5 HERTZ GPS UNITS FOR MEASURING DISTANCE, VELOCITY AND ACCELERATION IN FIELD HOCKEY SPECIFIC RUNNING PATTERNS

PLATEN, P.1, VOLKE, J.1, MAREK, E.1, BURGHAIUS, I.2, MANCHADO, I.3, HINRICHS, T.1

*1INSTITUTE OF SPORTS MEDICINE AND SPORTS SCIENCES, 2FACULTY OF MEDICINE, 3FACULTY OF EDUCATION, UNIVERSITY OF ALICANTE, SPAIN*

**Introduction:** GPS devices are more and more used in out-door sports for the analysis of sports specific running profiles, including the run profile of single players in field hockey. In the last years, 5 hertz (Hz) devices are used. However, validity of these devices concerning short distance movement analysis is unclear. Therefore, the aim of this study was to evaluate the validity of a GPS device (SPI Pro, GPSports, Australia) for measuring distance, velocity and acceleration in straight-line running courses with 180° changes of direction with a laser diode system as criterion measure. **Methods:** Ten healthy participants ( $n=5$  females;  $25 \pm 3$  years;  $1.77 \pm 0.12$  m;  $72 \pm 15$  kg) agreed to participate. Assessment of distance, mean and maximum velocity ( $v_{mean}$ ,  $v_{max}$ ) and maximum acceleration ( $a_{max}$ ) in straight-line running courses with 180° changes of direction were performed using GPS devices at 5 Hz and a laser diode system (LDS) at 100 Hz as criterion measure. Two test courses (20-m course: 5 m + 5 m + 10 m; 4-m course: 1 m + 1 m + 2 m) were performed at 4 different movement intensities (walk, slow run, fast run and sprint) with and without carrying a field hockey stick. **Results:** GPS data tended to slightly underestimate distance ( $0.19 - 0.51$  m),  $v_{mean}$  ( $0.05 - 0.37$  km/h),  $v_{max}$  ( $0.23 - 1.48$  km/h) and  $a_{max}$  ( $0.59 - 2.25$  m/s<sup>2</sup>) for the 4m- and 20m-course. For nearly all parameters variance increased with higher movement intensities and shorter distances covered. No significant differences could be found between running the courses with and without carrying a hockey stick for all parameters indicating that upper-body movements and the associated changes in the degree of the GPS device towards the satellite do not influence validity of the device. **Conclusions:** GPS technology is a sufficiently valid method to measure distance,  $v_{mean}$ ,  $v_{max}$  and  $a_{max}$  for short distance straight-line running courses with 180° changes of direction. Recordings of  $v_{max}$  and  $a_{max}$ , however, should be interpreted carefully especially when analysing rapidly changing directions over a short distance.

## THE EFFECT OF DIFFERENT EXECUTION PROTOCOLS OF WINGATE TEST ON MEASURES OF ANAEROBIC PERFORMANCE

DALAMITROS, A.1, ZAFEIRIDIS, A.2, CHRISTODOULOU, C.1, KELLIS, S.1,3

ARISTOTLE UNIVERSITY OF THESSALONIKI

**Introduction:** WAnT is a classic laboratory tool for the evaluation of anaerobic performance. The test determines peak power (PP), mean power (MP), and the fatigue index. The standard protocol includes maximal cycling for 30sec with the resistance progressively applied in 4sec. PP, MP, and fatigue index are determined from the six 5s-segments. Today, different execution protocols that modify the starting position of WAnT are used. Also, the calculation of WAnT parameters may be based on best 1s or 5s-averages. The aims of this study were to examine the effect of different WAnT execution protocols and the effect of different calculations on measures of anaerobic performance. **Methods:** Eleven men ( $24.3 \pm 2.7$  yrs) performed the WAnT using 4 execution protocols. In the 1st protocol (P1) the subjects were asked to cycle at 50rpm with no resistance. After stabilization, a 4sec countdown was applied. At the end of the countdown the resistance was applied with the drop basket and the subjects pedaled for 30s as fast as possible. In the 2nd protocol (P2), the resistance was set on the cycle-ergometer and the subjects started the 30-s test from a stationary position. In the 3rd protocol (P3), the 30s test started with maximal unloaded pedaling and the resistance was applied progressively in 4s. In the 4th protocol (P4), the 30s test started with maximal unloaded pedaling and the resistance was applied immediately at the 4sec with the use of a drop basket. Power was measured every second for the entire 30-s protocol. After each test, PP was calculated using the best 1s, 3s and 5s averages, and the best 5s-segment. The time to peak power, MP, and total work were calculated for all 4 execution protocols. **Results:** The values for PP were not significantly different among P1, P2 and P3, irrespective of method of calculation, but were lower compared to P4 ( $p < 0.01$ ). The method of calculation affected PP only in P4; that is the values of PP declined when using the best 1s, 3s and 5s averages, and the best 5s-segment (14.6, 13.3, 12.6 and 12.6 W/kg, respectively;  $p < 0.01$ ). MP and total work were significantly lower in P1, P2 and P3 vs. P4 ( $p < 0.05$ ). Finally, the time to peak power was longer in P1 and P2 vs. P3 and P4 ( $p < 0.01$ ). **Conclusion:** When using drop basket for the application of resistance during the WAnT, the protocols that do not involve maximal unloaded accelerations (P1 and P2) produce the more consistent results. The standardization of the execution protocol is necessary for computing and comparing the results of WAnT. The standardization procedure includes the starting position, the way of resistance application, and the method of calculation of measures of anaerobic performance.

## A RELIABILITY ANALYSIS OF THE 10M SPRINT TEST

DINSDALE, A.J, BISSAS, A.

LEEDS METROPOLITAN UNIVERSITY (LEEDS, UK)

**Introduction** The ability of an athlete to accelerate and develop maximum speed is a crucial factor in many athletic sports; hence the reliability when employing sprint tests is paramount. Guggenheimer et al., (2009) reported Intraclass Correlation Coefficient (ICC) ranging between 0.47 and 0.81 for multiple split times over a 40-metre sprint. However, limited evidence exists regarding statistical measures of absolute reliability in sprint running tests. The evaluation of measurement error is very important in studies where small changes in sprint times between conditions are expected (e.g. in Post-Activation Potentiation (PAP) research). Therefore, this study aimed to identify the degree of random error, due to performance variation, in the 10-metre sprint test. **Methods** Six trained males (age:  $20.6 \pm 1.3$  years, height:  $1.78 \pm 0.07$  m, mass:  $80.8 \pm 6.1$  kg) who regularly took part in sprinting activities were recruited. The design of the study comprised one familiarisation and two identical testing sessions separated by 48 hours. The testing sessions consisted of: a 15-min warm-up, 2 practice sprints and then 5 sprints over 10 metres tested by a Brower timing system. The sprints were performed from a three point start position, with the back foot placed within 1 metre of the starting line. Three statistical methods for assessing reliability were used after the data were assessed for heteroscedasticity: 95% Limits of Agreement (LOA), Coefficient of Variation (CV) and ICC (3, 1) consistency). Reliability results were obtained as follows: a) reliability based on the average score of the 5 sprints (R5); b) reliability based on the best sprint performance (RB). Results ICC values of 0.99 ( $p < 0.001$ ) were observed for both R5 and RB analyses. In terms of the random error expressed as a percentage of the grand mean, both R5 and RB analyses showed low random errors of 1.5% and 1.7% respectively, and very similar LOA. In particular, the LOA (Bias  $\pm$  Random Error) for R5 were:  $0.00 \pm 0.03$  s and the LOA for RB were:  $0.01 \pm 0.03$  s. Finally, both analyses displayed a very low CV (0.5%). **Discussions** The ICC values demonstrated a very high reliability between the testing sessions. Furthermore, a random error of 1.5-1.7% ( $\pm 0.03$  s) demonstrates that the 10-m sprint test has adequate stability to identify small changes in sprint performance in intervention studies where small changes in sprint times are expected. The data also showed that when the calculations involved the average score of 5 trials the random error was slightly reduced. The estimation of the random error is of high importance particularly in PAP studies where changes in sprint performance range from 2-3% (Tillin & Bishop, 2009). **References** Guggenheimer J, Dikin C, Reyes G, Dolny D. (2009) J Strength Cond Res, 23(4), 898-902. Tillin N, Bishop D. (2009) Sports med, 39(2), 147-166.

## IMPLICATION OF "505 AGILITY TEST" BY MEANS OF INSTANTANEOUS VELOCITY MEASUREMENTS FOR THE ASSESSMENT OF CUTTING MOVEMENTS AS USED IN FOOTBALL PLAYERS

KANEKO, K.1, HAKAMADA, N.1, KASHIWAGI, Y.2, FUNATO, K.2

1:SPORTS TRAINING CENTER, NIPPON SPORT SCIENCE UNIVERSITY (TOKYO, JAPAN), 2 :LABORATORY FOR HUMAN MOVEMENT SCIENCES, NIPPON SPORT SCIENCE UNIVERSITY (TOKYO, JAPAN)

**Introduction** "505 agility test" is a relatively simple test that measures the time for acceleration, deceleration and rapid change of direction over a short course with a running start. Subject should sprint from starting line, through the light gates to the zero line, where they are required to turn on either the left or right foot and then accelerate off the line back through the light gates (Australian Sports Commission 2000). Not only sprint ability but also cutting quickness might be one of the important factors for ball game players such as football. Therefore, purpose of this study were to examine the validity of the "505 agility test" by measuring instantaneous velocity changes and to evaluate specific ability in football (soccer) players. **Methods** During "505 agility test" trial, instantaneous velocity was measured by laser measuring instrument system (100Hz, Laveg, Germany) as well as 2D and 3D motion monitoring devices by high Speed Camera (500fpf, Fastcam SA3, Photron, Japan) and VICON motion capture system (100Hz, Oxford Metrics, England), respectively. All these data were synchronized with photo cell triggering device measured the elapse time taken for 5-meter interval shuttle sprint. Agility and kinematic data were taken from 14 male youth soccer players (age  $17.0 \pm 1.5$  years, body mass  $61.2 \pm 5.9$  kg). From Laveg measurements, following parameters were taken for the analysis: distance where maximum sprint velocity attained, maximum sprint velocity, from maximum sprint velocity ( $V_{max}$ ) and %decline in velocity at final goal. Results 505 time (mean $\pm$ SD) was  $2.43 \pm 0.11$  seconds and high correlation was

shown between 505 time measured by photo cell and by Laveg ( $r=0.9149$ ,  $p<0.001$ ). Maximum instantaneous velocity (mean $\pm$ SD) was  $6.88\pm0.25$  m/s which appeared at  $1.4\pm0.40$  m before approaching 5m interval shuttle run zone. No statistically significant correlation was observed between maximum velocity and 505 time. Discussion 505 agility time might be determined by not simply maximum sprint velocity but some complicated factors such as acceleration/deceleration abilities and cutting movement quickness. Draper and Lancaster (1985) introduced 505 agility test for the assessment of one of the important physical abilities in football player. From preset study, 505 agility test might be valid for evaluating cutting movement performance as used in football players. References Draper JA, Lancaster MG. (1985). ## PLANNING AND MONITORING IN-SEASON TRAINING LOADS IN TEAM SPORTS BY MEANS OF MATCH DIFFICULTY AND SESSION-RPE

SCHULTZ DE ARRUDA, A.F.1, AOKI, M.S.2, FREITAS, C.G.1, KISS, M.A.P.D.1, MOREIRA, A.1

1: SCHOOL OF PHYSICAL EDUCATION AND SPORT, UNIVERSITY OF SÃO PAULO (BRASIL), 2: SCHOOL OF ARTS, SCIENCES AND HUMANITIES, UNIVERSITY OF SAO PAULO.

Introduction A inherent problem in team sports periodization is determining the appropriate training loads during the competitive phase of the season. With this in mind, COUTTS & KELLY (2007) proposed a model that can be used to guide in season training loads in team sports, taken account the predict match difficulty and the session-RPE method (internal training load; Foster, 1998). However, we have found no study analyzing the association between the variables used in this model. Thus, the aim of this study was to examine the relationships among the difficulty of the games scheduled at the beginning of the season (DBS), the in-season match difficulty (DIS and the weekly internal training load (ITL). Methods Twelve professional male basketball players were investigated across a competition phase ( $25.3\pm 5$  years,  $97.6\pm 15$  kg, and  $195.8\pm 10.5$  cm). The monitoring model proposed by KELLY & COUTTS (2007) was adopted. The predict match difficulty (DBS) was determined before the commencement of the season by calculating the sum of "level of opposition", training days between matches and match location. The training intensity for each session was calculated using the CR-10 RPE scale. The DIS was determined reassessing the DBS on a weekly basis. The relationship between DBS, DIS and ITL was determined by means of Pearson correlation coefficient ( $p < 0.05$ ) Results Significant correlations were detected between DBS, and DIS ( $r = 0.86$ ) as well as between DBS and ITL ( $-0.59$ ) and DIS and ITL ( $-0.65$ ) Discussion The results of the present study indicate that the predicted level of difficulty of a match is useful to determine the training load for the week. The significant negative relationship between DBS and ITL suggests that when the predicted match difficulty was considered low, greater training load was planned. However, despite of the significant relationship between DBS and DIS, the DIS seems more accurate to manipulate the ITL. Greater coefficient of relationship was observed between DIS and ITL suggesting the needs to reassesses the DBS on a weekly basis to provide appropriate feedback to coaches which in turn can use this information to plan the in-season training loads. ## CORRELATION PARAMETERS FOR INVASIVE AND NON-INVASIVE CONTINUOUS AND INTERVALS TRAINING SESSIONS IN COLLEGE PLAYERS

GONELLI, P.R.G., CESAR, M.C., MONTEBELO, M.I.L., BORIN, J.P., SIMÕES, R.A.

METHODIST UNIVERSITY OF PIRACICABA

CORRELATION PARAMETERS FOR INVASIVE AND NON-INVASIVE CONTINUOUS AND INTERVALS TRAINING SESSIONS IN COLLEGE PLAYERS Gonelli, PRG.1, Cesar, MC.1, Montebelo, MIL.1, Borin, JP.2, Simões, RA. 1:UNIMEP (Piracicaba, Brazil), 2:UNICAMP (Campinas, Brazil) Introduction The scientific advancement reaches all worldwide areas, not being different with sports, soccer has had many advances in the process of evolution, so evaluation and control of drills and matches is essential, for this, invasive parameters (IP) and non-invasive (NIP) are used, all with the goal of keeping the athletes at the level of excellence and able to face the current calendar. So, the aim of this study was to correlate (IP) and (NIP) in continuous training sessions (CTS) and interval (ITS) in college soccer players. Methods There were 10 players, between 17 to 24 years old, they performed two r sessions, an CTS, running 40 minutes at the speed of the anaerobic threshold, and ITS, sprints of 10, 20 and 30 meters, followed by 30, 45 and 60 seconds of recovery between sprints respectively. At the beginning and end (1st, 3th and 5 th minutes) of the sessions blood was collected for measurement of lactate, and the peak value used for analysis (Denadai et al., 1995), and asked the subjective rating of perceived exertion for dyspnea (RPED) and neuromuscular (RPEN), through the Borg scale (Borg, 1982). To correlate the data of lactate RPED and RPEN was used the Spearman coefficient,  $p < 0.05$  was adopted. Results The value of lactate peak was larger in the ITS ( $5.07$  mmol/l) compared to the CTS ( $4.00$  mmol/l), RPED and RPEN also had a higher value in ITS ( $14.8$  and  $15.2$ ) compared to CTS ( $13.8$  and  $13.8$ ). Only the results between lactate and end RPEN demonstrate high correlation and significant ( $r=0.76$ ,  $p=0.01$ ). Discussion From this data it can be observed that the ITS is more intense and showed that the lactate values were better correlated with the neuromuscular question. Using IP and NIP are important, so it is worth noting that if there is the possibility of using more of an intensity of training and matches can be better analyzed, since the use of these indicators are used at different times of periodization and games and has been investigated in researches (Castagna et al., 2007, Mohr et al., 2010). ## EFFECTS OF DIFFERENT TRAINING PROTOCOLS ON AEROBIC CAPACITY AFTER 6 MONTHS OF INTERVENTION IN OVERWEIGHT PEOPLE

BARBERO, M.F., PEINADO, A.B., MORENCOS, E., BUTRAGUEÑO, J., CUPEIRO, R., CALDERÓN, F.J., BENITO, P.J.

UNIVERSIDAD POLITÉCNICA DE MADRID

Introduction Maximal aerobic capacity ( $VO_{2max}$ ) is a stronger cardiovascular diseases indicator, mortality predictor and is related with other health factors (1). The aim of this study was to determine which training protocol is the most effective to improve the  $VO_{2max}$  in overweight people. Methods Ninety overweight people, men and women (18 – 50 years; BMI > 25 and < 30 kg/m<sup>2</sup>), participated in the study. Each subject performed two incremental tests, before and after intervention, until exhaustion to determinate  $VO_{2max}$  on a treadmill, using a modified Bruce protocol (2). Subjects were randomized to one of the following training groups: strength training (ST; n = 22),

aerobic training (AT; n = 25), a combination of AT and ST (COM; n = 23) (Training frequency: 3 times per week / Intervention: 24 weeks) and control group (CG; n = 20). All of them in combination with the same diet restriction. Two way ANOVA with repeated measures was used to determine differences between pre and post intervention in each training group. The significant level was set at  $\alpha \leq 0.05$ . Results Significant improvements in VO2max (mL/min) were obtained in all groups although the highest increases were in ST (Pre.  $3180.6 \pm 704.1$  vs. Post.  $3788 \pm 509.5$ ) and COM (Pre.  $3277.2 \pm 589.1$  vs. Post.  $3859.4 \pm 430.2$ ) in men. In women, we have obtained significant improvements in VO2max (mL/min) in all groups, except in ST. Aerobic training group obtained the highest increase in women (Pre.  $2021.5 \pm 263.3$  vs. Post.  $2367.1 \pm 374.4$ ). When we compare the results of VO2max related to body mass (mL/min/kg) significant improvements in all groups were obtained. Discussion In young women, Poehlman et al. (2002) obtained similar results to us because the strength group did not improve. Sillanpää et al. (2009) obtained similar results with older women, all groups improved VO2max, except the ST group. Stensvold et al. (2010) obtained the highest improvements in aerobic and combined training groups, in contrast to our results, since we obtained improvements in ST in men too. We can conclude that aerobic training improves VO2max in women while in men the improvements are greater in strength training groups (ST and COM). References 1. Stensvold D, et al. ## ANALYSIS OF ANAEROBIC THRESHOLDS DETECTING METHODS BY RESPIRATORY GAS EXCHANGE

IM, J.1, JEON, Y.2, AHN, M.3, KIM, D.4, KANG, Y.5, KIM, C.6, KIM, B.7

1,2,3,4,5:KAIST(S.KOREA), 6,7:DAEJEON U.(S.KOREA).

There are some well-known respiratory gas exchange methods for finding the anaerobic threshold (AT) during incremental exercise test. In this study, we found more useful way to detect the AT values and compare these AT values with those obtained from gas exchange variables by three different methods. We randomly chose 49 men and then accomplished a Bruce protocol test on treadmill. Respiratory gases were registered constantly, and gas exchange variables are calculated by computers. VO2 values at AT were acquired by 3 ways and analyzed; 1) VO2 at V-slope method (Vslope-AT), 2) VO2 at VE/CO2 versus O2 curve (EqCO2-AT), 3) VO2 at Respiratory Exchange Ratio method (RER-AT). We also tried to figure out the influence of the unit of the measurements. So VO2 values at AT were computed by 3 different units; 1) Normal VO2 (mL/min) nVO2, 2) Specific VO2 (mL/min/kg) sVO2 3) Percentage of the VO2max pVO2. We found that Vslope-AT is powerfully correlated with nVO2 at EqCO2-AT( $r=0.960^{**}$ ,  $P<0.01$ ), with sVO2 at EqCO2-AT( $r=0.962^{**}$ ,  $P<0.01$ ), and pVO2 at EqCO2-AT( $r=0.721^{**}$ ,  $P<0.01$ ). sVO2 had higher Pearson correlation coefficient(Pearson R) than nVO2 and pVO2. We also supported that the RER-AT is weakly correlated with Vslope-AT and EqCO2-AT; sVO2 at Vslope-AT( $r=0.772^{**}$ ,  $P<0.01$ ), sVO2 at EqCO2-AT( $r=0.743^{**}$ ,  $P<0.01$ ). We also acquired linear regressions between those variables. The VO2max could be estimated with above variables by a linear regression analysis; [VO2max =  $1.176(\text{Vslope-AT}) + 7.588$  with SEE of  $\pm 3.00$ ;  $r=0.922$ ], [VO2max =  $1.280(\text{EqCO2-AT}) + 4.800$  with SEE of  $\pm 2.03$ ;  $r=0.961$ ], and ; [VO2max =  $1.239(\text{RER-AT}) + 1.552$  with SEE of  $\pm 2.03$ ;  $r=0.766$ ]. In conclusion, the EqCO2-AT is more easy way to estimate the AT than v-slope method. In several cases v-slope method didn't show us some accurate point of inflection point which is AT. Even in this case EqCO2-AT method show that point better than V-slope method.

#### MAINTAINING HAMSTRINGS TO QUADRICEPS RATIO IN ELITE ACADEMY SOCCER PLAYERS THROUGH A STRENGTH AND CONDITIONING PROGRAMME

FRUER, S., KEENAN, J., NOON, M., THAKE, C.D.

COVENTRY UNIVERSITY

Introduction Within soccer the majority of injuries occur in the lower extremity, with the highest proportion being attributed to hamstring strains (Woods et al. 2004). Although the aetiology remains unclear a potential factor is a muscle imbalance between quadriceps (Q) and hamstrings (H) (Croisier, 2004). Indeed a H eccentric : Q concentric ratio of higher than 1.4 is considered protective against H injuries (Croisier et al. 2008). Furthermore, both soccer training and match play have recently been shown to develop the knee musculature towards Q dominance (Iga et al. 2009) and lead to a reduction in the H : Q ratio (Greig, 2008). Considering this, the development of a players athletic ability should be directed towards accommodating a balanced development of this apparently functionally important ratio alongside strength gains. Aim To evaluate changes in strength and H : Q ratio within elite academy players through a 18 month strength and conditioning programme. Methods 5 elite football academy players ( $17.4 \pm 0.1$  yrs;  $1.76 \pm 0.73$  m;  $66.2 \pm 5.6$  kg) undertook a 18 month (once or twice a week in season) strength and conditioning programme consisting firstly of developing technique (1st month) followed by a periodised programme consisting of strength and power phases. The programme mainly consisted of snatch and clean and jerk and derivatives of these exercises plus stiff leg deadlifts and nordic hamstring curls. The ratio of peak eccentric H strength ( $30^\circ/\text{s}$ ) to peak concentric Q strength ( $240^\circ/\text{s}$ ) (Croisier et al. 2008) was assessed pre and post intervention upon an isokinetic dynamometer (Cybex, Humac Norm System). Data were analysed using paired t-test. Results Q and H peak torque increased in both the right (17%,  $P=0.08$ ; 32%,  $P=0.06$ ) and left (22%,  $P=0.05$ ; 16%,  $P=0.15$ ) respectively. The H : Q ratio was maintained (right limb  $1.1 \pm 0.2 - 1.3 \pm 0.3$ ; left limb  $1.2 \pm 0.2 - 1.1 \pm 0.2$ ). Discussion Including eccentric H exercises (stiff leg deadlifts / nordic hamstring curls) within a strength and conditioning programme appears to assist with maintaining an acceptable H : Q ratio (Croisier et al. 2008) when developing a players athletic ability, potentially reducing both the immediate and long term risk of H injuries. ## STRENGTH ASSYMETRIES OF THIGH MUSCLES IN YOUNG ELITE SOCCER PLAYERS

MALÝ, T., ZAHALKA, F., MALA, L., HRASKY, P., BUZEK, M., GRYC, T.

FACULTY OF PHYSICAL EDUCATION AND SPORT, CHARLES UNIVERSITY PRAGUE

**Introduction** Since the game of soccer frequently involves one-sided activities such as kicking, tackling and passing, asymmetries in muscle strength between both legs are possible. Croisier et al. (2005) indicate that the isokinetic strength assessment before the start of the season enables identification of strength indicators as predictors of possible muscle injury. Lehance et al. (2009) present a higher proportion of muscle strength imbalances in young soccer players in comparison to senior players. **Methods** Twenty five soccer players of U16 national team (mean age  $15.6 \pm 0.2$  years, body height  $177.4 \pm 6.8$  cm and body weight  $67.0 \pm 7.7$  kg) participated in this study. Assessment was performed on the isokinetic dynamometer Cybex Humac Norm. Following parameters were obtained in concentric contraction during five velocities (60,120,180,240,300°/s) for dominant (D) and non-dominant leg (N): Peak torque (PT), quadriceps (QD:QN) and hamstring (HD:HN) ratio, ipsilateral ratio between H and Q for both legs (HD:QD; HN:QN). Student t-test for pair comparison or RM ANOVA was used for statistical assessment. **Results** Significant differences were found between PT of extensors at 240 and 300 °/s and flexors at the lowest velocity ( $p < 0.05$ ). H:Q ratio between legs at 240 °/s was significantly different ( $p < 0.05$ ). With increasing angular velocity, statistical differences in QD:QN ( $F_{4,96} = 0.802$ ;  $p > 0.05$ ) respectively HD:HN ratio ( $F_{4,96} = 0.133$ ;  $p > 0.05$ ) were not revealed. However HD:QD or HN:QN, respectively, significantly changed during increasing velocity ( $F_{4,96} = 7.588$ ;  $p < 0.05$  or  $F_{4,96} = 6.696$ ;  $p < 0.05$ ). HD:HQ at the lowest velocity was significant when compared to each other velocity ( $p < 0.05$ ). HN:QN at 60°/s was different in comparison to HN:HQ at 120 or 300°/s, respectively. **Discussion** The bilateral ratio was not significantly different from the angular velocity. Croisier et al. (2003) indicate a risk bilateral difference between concentric muscle strength in professional players higher than 15%. In our case, 15 players (60 %) reached this value minimum at one velocity. It is in line with Lehance et al. (2009) who reported that up to 56% of the players are at risk of muscle strength imbalances of knee flexors or extensors. The H:Q ratio raised with increasing angular velocity in both preferred and non-preferred extremities. H:Q ratio during the lowest velocity revealed the lowest value of H:Q in both legs. This project was supported by GACR P407/11/P784 and MSM 0021620864. **References** Croisier JL, Reveillon V, Ferret JM, Cotte T, Genty M, Popovich N, Filho, M, Faryniuk JE, Ganteaume S, Crielaard JM. ## THE EVALUATION OF MUSCLE FLEXIBILITY IN YOUNG SOCCER PLAYERS

BELLAFIORE, M.1,2, BATTAGLIA, G.1,2, CARAMAZZA, G.1,2, TONA, P.2, PALMA, A.1,2

UNIVERSITY OF PALERMO

**Introduction** The agility and coordination are two of many attributes required to become a successful player. Several reports have showed that the training of muscle flexibility leads to improvements both in the coordinative and technical performance, and in the process of motor learning (1). The aim of our study was to evaluate the flexibility of shoulders, trunk and lower limbs in young male soccer players compared to that of sedentary subjects. **Methods** Twelve players (age:  $20.00 \pm 3.74$  years; weight:  $74.25 \pm 6.80$  kg; height:  $178.92 \pm 6.65$  cm) belonging all to the same soccer team and ten sedentary subjects (age:  $21.8 \pm 3.12$  years; weight:  $73.60 \pm 5.29$  kg; height:  $179.50 \pm 5.78$ ) were tested. The players had  $11.75 \pm 3.57$  years of experience in soccer game and 58% of them had undergone injuries (58% in upper limbs and 1.7% of them also in lower limbs). The sedentary subjects presented about 30% of injuries in upper limbs and 3% also in lower limbs. Low back and hamstring flexibility was measured by the sit and reach test. The range of motion of hip abduction was measured with a goniometer. The flexibility of shoulders was evaluated by a full circumduction of both arms and the lateral flexion of trunk with a measuring scale fixed to the wall. **Results** Soccer players had a higher flexibility of shoulders and trunk than sedentary subjects; however this difference was not significant ( $p > 0.05$ ). Moreover, the players showed a significant increase in range of motion of hip abduction compared with sedentary subjects and, in particular, the right hip was more flexible compared with the left one. The range of motion of hip abduction was not related to the age and body mass index of the soccer players. **Discussion** The difference of flexibility between the body upper and lower part in soccer players may be due to a scarce and unspecific training of shoulder and trunk flexibility compared with legs. This difference might provoke a postural unbalance with higher risks of injuries (2) due to falls and lower technical-coordinative performance. **References** (1) Gleim GW, McHugh MP. Flexibility and its effects on sports injury and performance. *Sports Med* 1997; 24: 289-99. (2) Witvrouw E et al. Muscle flexibility as a risk factor for developing injuries in male professional soccer players. A prospective study. *Am J Sports Med* 2003; 31: 41-6.

## COMPARISON BETWEEN ADOLESCENT AND COLLEGIATE SOCCER PLAYERS IN CHANGES IN DEEP ABDOMINAL MUSCLE THICKNESS DURING DRAW-IN MANEUVER USING ULTRASOUND IMAGING

WATANABE, H.

KITASATO UNIVERSITY

Watanabe, H.1, Yoshimoto, M.2, Fujii, M.1, Ashihara, M.2, Torii S.3., Uchida, Y.2, Takahira, N.1 1: Department of Rehabilitation, Kitasato University School of Allied Health Sciences (Kanagawa, Japan), 2: Graduate School of Medical Science, Kitasato University (Kanagawa, Japan), 3: Waseda University, Faculty of Sports Sciences (Saitama, Japan) **Introduction** Adolescent athletes show a high incidence of onset of low back pain (LBP) during sports activities. Development and increased contractility of the deep abdominal muscles have been found to improve the spinal stability and prevent LBP. Researchers have shown that the ability of the transversus abdominis (TrA) muscle to contract is important for decreasing the likelihood of onset of LBP during sports activities. The purpose of this study was to clarify the characteristics of abdominal deep muscles in adolescent soccer players. **Methods** The participants in this study were 53 soccer players (mean age, 13.6 years) from junior high school and 14 collegiate soccer players (mean age, 23.4 years). The deep abdominal muscles of both sides were imaged by brightness-mode (b-mode) ultrasonography (SSD-4000, ALOCA Co Ltd, Tokyo). Abdominal muscles on the dominant leg side were selected as the targets of measurements, and measurements of the TrA muscle and internal oblique (IO) muscle were conducted. The muscle thickness of these muscles was measured at rest and during contraction (while drawing-in of the abdominal wall). **Results** No significant differences were noted in the thickness of the TrA (adolescent players;  $3.5 \pm 0.9$ , collegiate players;  $3.5 \pm 0.9$ ) or IO muscle (adolescent players;  $8.5 \pm 2.1$ , collegiate players;  $10.1 \pm 2.5$ ) at rest, whereas significant differences were noted in the thickness of the TrA (adolescent players;  $4.5 \pm 1.3$ , collegiate players;  $6.1 \pm 1.7$ ) and IO (adolescent players;  $8.9 \pm 2.2$ , collegiate players;  $12.7 \pm 3.4$ ) muscle during the draw-in maneuver between the two groups. Significant differences between the two groups were also noted in the percent changes of the muscle thickness of both the TrA and IO muscles. **Discussion** The findings of the study revealed that the adolescent soccer players showed immature functioning of the deep abdominal muscles, suggesting that adolescent soccer players need to

train their deep abdominal muscles in order to prevent LBP. References Richardson CA, Snijders CJ, Hides JA, Damen L, Pas MS, Storm J. (2002). Spine (Phila Pa 1976), 27,399-405. ### COMPARAISON BETWEEN TWO TYPES OF INTERVAL TRAINING IN SOCCER PLAYERS: PHYSIOLOGICAL AND PERCEPTIVE SOLICITATIONS.

LE MOAL, E.1, DRUST, B.2, DULUC, C.1, ZOUHAL, H.1

1 M2S LABORATORY, UNIVERSITY OF RENNES II-ENS CACHAN, FRANCE. 2 RISES, LJM UNIVERSITY, LIVERPOOL, UNITED KINGDOM.

**Introduction** Endurance is considered as an important factor of performance in soccer (Iaia et al., 2009). It is now well accepted that high intensity intermittent exercise (HIIE) may develop endurance. Since few years, other methods appear such as small-side games or specific track. One of those tracks is the Höff track (Höff et al., 2002). This last seems present good results despite the lack of data concerning the physiological and perceptive solicitations compared to a HIIE. Therefore, the purpose of this study is to compare the physiological and perceptive solicitations of two HIIE: 15s/15s at 120% of maximal aerobic speed (MAS) and an integrated exercise on the Höff track (Höff T). **Methods** Seven high level soccer players (24.1±4.5 yrs) realized a maximal graded test to determine their peak oxygen uptake (VO<sub>2peak</sub>), MAS and peak heart rate (HR<sub>peak</sub>). During the same week, they realized two randomized exercise: 1) physical controlled exercise (15s/15s Test) at 120% of MAS (corresponding to 90-95% of HR<sub>peak</sub>) during 4×4 minutes with 3 minutes of active recovery between series and 2) four sets of 4 minutes in the Höff T to dribbling the ball at an intensity of 90-95% of HR<sub>peak</sub> interspersed with 3 minutes of active recovery. The intensity of the active recovery was closed to 70% of HR<sub>peak</sub> during the two tests. HR, oxygen consumption (using a gas exchange telemetric system: VO<sub>2000</sub>, Medical Graphics, Minnesota, USA), lactate and rating of perceived exertion (RPE) were measured. **Results & Discussion** The mean VO<sub>2</sub> were significantly higher ( $p < 0.05$ ) during the Höff T ( $2.67 \pm 0.30$  mL/min;  $39.3 \pm 2.3$  mL/min/kg) than during the 15s/15s Test ( $2.49 \pm 0.34$  mL/min;  $36.8 \pm 1.9$  mL/min/kg). On the same way, the total O<sub>2</sub> consumed was significantly higher ( $p < 0.05$ ) during the Höff T ( $66.8 \pm 7.6$  L) than during the 15s/15s Test ( $62.3 \pm 8.6$  L). Blood lactate concentration was significantly higher after the first set of the Höff T ( $12.5 \pm 2.0$  mmol/L) than the 15s/15s Test ( $10.6 \pm 2.0$  mmol/L). Hence, as shown by the RPE score values, players perceived the 15s/15s test more difficult than the Höff T ( $13 \pm 1.8$  vs.  $11.7 \pm 1.4$ ,  $p < 0.05$ ). **Conclusion** Our results demonstrate that players consume more oxygen and produce more lactate during the Höff T than during the 15s/15s (especially during the first set). Despite that, they perceived the Höff circuit less difficult than 15s/15s test. Thus, the use of the Höff T for aerobic training appears as an interesting alternative to develop endurance in soccer players. However, fitness coaches had to propose this Höff circuit so far from the soccer game because it may induce more anaerobic participation to the energy production. References Iaia, M et al., (2009). Int J Sports Physiol Perf, 4(3):291-306 Höff, J et al., (2002). Bri J Sports Med, 36(3):218-221

### THE EFFECT OF 12-WEEKS CORE EXERCISE ON SOCCER SKILL AND PHYSICAL FITNESS IN MIDDLE SCHOOL SOCCER PLAYERS.

LEE, H.J., YOUN, K.S., PARK, K.S., JEON, C.B., KWAK, H.M., JEON, I.S., KIM, J.H.

UNIVERSITY OF ULSAN, KOREA

The purpose of this study was to investigate the effect of 12-weeks core exercise on soccer skill (accuracy of passing, shooting, and kicking) and physical fitness (agility, muscle endurance, balance, flexibility, VO<sub>2max</sub>, isokinetic muscle strength) in middle school soccer players. Twenty four male students ( $14.5 \pm 0.05$  yrs) were participated. They were divided into two groups (core exercise group vs non-core exercise group). Core exercise was composed of 8 exercises (prone balance, balanced push-up, russian twist, v-sit ball transfer, supine resisted pull-in, back extension, triceps blaster, squat to overhead press). Core exercise group was performed at 30 repetition and 5 sets each other. Repeated measured ANOVA method was used to examine the differences by each factor between the two groups before and after the training. Significant level was .05. Main results of comparative analysis between difference two groups were as follows. First, for physical fitness, there were differences between the two groups in agility, balance, muscle strength and there were no differences in cardiopulmonary endurance, flexibility, anaerobic power, muscle endurance. Secondly, for soccer skill, there were no differences between the two groups. In conclusion, there were significant improvements in agility, balance, and muscle strength through 12-weeks core exercise training, and the most improved factor was balance. But core exercise alone does not improve accuracy of soccer skill. So skill training and core program should be combined in order to improve overall soccer performance.

### FATIGUE AND RECOVERY IN SOCCER – A STUDY OF AEROBIC PERFORMANCE ABILITY MARKERS

DILLERN, T., SHALFAWI, S.

UNIVERSITY OF NORDLAND

**Introduction:** During the last decades the demands of competition in soccer has increased (Bloomfield, Polman, & O'Donoghue, 2007) (Bangsbo, Mohr, & Krstrup, 2006). The development is for periods leading to difficulties in obtaining high-quality training weeks. Implementing recovery strategies have thus become even more important. In soccer the recovery phase consists of a reversal of the changes that has occurred during match-play. Knowledge of what fatigue in soccer consists of and how it reestablishes when the match is over is therefore essential to execute targeted recovery actions. Previously published data on fatigue and recovery in soccer has been criticized because of its narrow measurement methods (Dawson, Gow, Modra, Bishop, & Stewart, 2005). The purpose of this study was therefore to examine fatigue and recovery in soccer with aerobic and holistic performance ability markers. **Methods:** 17 male soccer players (18-31 years) underwent a laboratory testing protocol containing aerobic performance markers 7 ( $\pm 4$ ) days before a soccer match (pre-test), immediately after the match (post test) and 24 hours after the match (post2test). To examine fatigue the difference between pre- and post-test was investigated and to examine recovery the difference between pre-and post2test was investigated. **Results:** The findings of fatigue shows a significant reduction in aerobic performance ability after the soccer match compared with before the match. For all variables, results were significantly decreased (0.9-34.3 %) after the match ( $p < 0.05$ ). Regarding recovery the findings show that the players were about to reestablish their performance, but that full recovery was still not achieved. **Discussion:** This study shows that soccer players have significantly reduced aerobic performance ability after a soccer match compared with before the match. Furthermore, it appears that this performance capability is not fully rebuilt 24 hours after the match ends. These findings are in agreement with previously published data and can be explained by both metabolic (glycogen depletion) and mechanic fatigue (muscle damage and inflammatory responses). ### TACTICAL ANALYSIS OF THE REAL MADRID OFFENSIVE PROCESS

BARBOSA, A.1,3, SARMENTO, H.1,2,3, MARTINS, N.1,2, LEITÃO, J.1,2, CAMPANIÇO, J.1,2

*INSTITUT NACIONAL D'EDUCACIO FÍSICA DE CATALUNYA*

1-UTAD, Vila Real, Portugal 2-CIDESD, Portugal 3-UB, Barcelona, Espanha Introduction The detection and analysis of regular structures of behavior in Football has received increasing attention from researchers and trainers. The main purpose of this study was to detect temporal regular structures (t-pattern) of behavior in the Real Madrid Offensive Process, in the 2010/2011 sporting season. Methods To collect data, we coded nine games of the Real Madrid football team, using the observational instrument developed and validated by Sarmento et al. (2010). We used the software THEME 5.0 for the detection of the t-patterns which is a professional system for detecting and analyzing hidden patterns in behavior, by performing intensive structural analysis of behavioral data. The study of the reliability shows high levels (above 0.95 for all criteria) for the intra-observer agreement. The level of significance was set at 0.005. Results and Discussion We detected six completed t-patterns (were repeated seven times) referring to the whole process, from recovering possession of the ball until completing the offensive process (OP) success fully. The analyze of the completed t-patterns, allow us to understand that the area of recovery of possession is the defensive midfield. In all detected patterns the second action happens in another zone of field always in a lateral corridor. After the ball gets to the offensive midfield, there is a rapid and long change of the playing area and then the team tries to quickly end the O.P.. All the patterns ended when the ball entered the zone eleven (offensive third). This was a constant in all found patterns. We identified also patterns that ended with relevant actions such as goals, shot on goal or shot defended by goalkeeper. Conclusion The results suggest that collecting a larger volume of data allowed us to detect more temporal patterns and more frequently repeated ones. This type of analyses in the natural context (the game), enable us to obtain information on how to organize the training process, so that the team understand ways to enhance the team's potential and oppose adversary actions of success. These preliminary results demonstrate the potential of THEME 5.0 software for detecting structures regular behavior in football. References (1) Sarmento, H., Anguera, T.; Campaniço, J. & Leitão, J. (2010). Development and Validation of a Notational System to Study the Offensive Process in Football. *Medicina(Kaunas)*, 46(6), 401-407.

### TEMPORAL INTERACTION PATTERNS IN THE OFFENSIVE PROCESS OF REAL MADRID FOOTBALL TEAM

BARBOSA, A.1,2, SARMENTO, H.1,2,3, MARTINS, N.1,2, LEITÃO, J.1,2, CAMPANIÇO, J.1,2

*INSTITUT NACIONAL D'EDUCACIO FÍSICA DE CATALUNYA*

1-UTAD, Vila Real, Portugal 2-CIDESD, Portugal 3-UB, Barcelona, Espanha Introduction The main purpose of this study was to investigate the existence of regular behavior patterns in Counter-Attack (C.A.) and Fast Attack (F.A.) of Real Madrid (RM) football team in 2010/2011 sporting Season. Materials and Methods To collect data, we used the instrument developed and validated by Sarmento et al. (2010). This instrument consists in a specific notation analysis tem to study the offensive process and its variables. Several offensive sequences were coded through the observation of nine games of RM football team. In order to verify the occurrence of patterns, we used the software THEME 5.0, which is a professional system for detecting and analyzing hidden patterns in behavior, by performing intensive structural analysis of behavioral data. It detects complex repeated patterns that otherwise remain hidden. The reliability of the data was calculated by the intra observer agreement, and values above 0.95 were achieved for all the variables. For the detection of the patterns, we only considered the ones that repeated three times, and the significance level was set at 0.005. Results We detected seven completed t-patterns, referring to the whole process, from recovering possession of the ball until completing the offensive process (OP) successfully. In the C.A., we verified the existence of two patterns, one of which ended in goal. In the F.A., we verified the existence of five patterns. Four patterns ended with a shot from the frontal zone of the goal. Discussion The analysis of the t-patterns allows us to conclude that the area of recovery of the ball possession is the midfield, with preponderance in the defensive midfield. In all detected patterns, the second action happens in another field zone, with great impact on the opposite lateral corridor. After the ball gets to the offensive sector, there is a rapid and long change of the playing area and then the team tries to quickly end the OP. The attack ends or passes again to the corridor where it started. There is high incidence of the game in the lateral corridors. The players tried to make the last pass for the area 10 (left corridor, attacking third). If the last pass is not performed in this zone, the next action is performed in the zone 9, or 12 (right corridor), where the players try to perform a goal by shot. This was a constant in all the patterns found. In C.A. there is a pattern that ends in a goal. Of these seven patterns found, both on C.A. and F.A., the pattern that ends in a goal is the only action that ends with numerical superiority. Conclusion This evidence seems to complement other studies about efficiency but shows them as repeated actions. The behavior in an acyclic, inconstant sport can have patterns that lead to success. ### INFLUENCE OF DIFFERENT RECOVERY INTERVALS ON PERFORMANCE DURING REPEATED SWIMMING SPRINTS.

THEOS, A., TAMPAKI, M., FRAGOULIS, G., MARIDAKI, M.

*UNIVERSITY OF ATHENS*

In many team sports participants produce repeated maximal or near-maximal efforts of short duration with brief recovery periods (1). Recovery duration seems to influence performance in case of repeated sprints (2). Therefore, the purpose of the present study was to examine the influence of two different recovery intervals on performance during repeated swimming sprints. Thirteen female water polo players (age:  $19.1 \pm 0.8$  yrs, height:  $169.8 \pm 1.6$  cm, body mass:  $71.8 \pm 1.7$  kg, mean  $\pm$  SE) participated in this study. Participants performed 4x50m (L occasion) and 8x25m (S occasion) sprint swimming tests in random order. On L occasion the recovery interval after each sprint was 14sec, while on the S occasion the interval was 6sec so that the total recovery time was 42sec in both occasions. Blood samples were collected from finger 3 minutes after the end of each occasion and lactate concentrations ([La]) were calculated. Differences between the two occasions in performance time and [La] were analyzed using T-Test. Results are presented as mean  $\pm$  SE. Total performance time was significantly different between the two occasions ( $L=149.1 \pm 1.7$  vs  $S=143.1 \pm 2.1$  sec,  $p<0.001$ ). Despite the difference in performance time, [La] did not differ significantly ( $L=5.9 \pm 0.2$  vs  $S=5.6 \pm 0.2$  mmol/L,  $p=0.22$ ). The results of the present study suggest that despite the fact that total recovery time and total distance covered (200m) were the same in the two occasions, there was a significant difference in performance as a result of the recovery pattern in the case of S occasion. 1. ## COMPARATIVE STUDY ON RECOVERY BETWEEN FIRST AND SECOND DIVISION FOOTBALL PLAYERS OF THE SPANISH LEAGUE.

RAMOS, J.2, GALINDO, M.1, CALDERÓN, J.1, SEGOVIA, J.2, LÓPEZ-SILVARREY, J.2

*\*UNIVERSIDAD POLITÉCNICA DE MADRID; \*\*UNIVERSIDAD COMPLUTENSE DE MADRID*

**Introduction:** several studies on high intensity intermittent exercise have stated that performance capacity at high intensity phases of exercise depend on the duration of the recovery phase and on the intensity of the exercise carried out at such phase (1-3). The difference found on recovery parameters between football players might be one of the factors that determine their performance on the match. **Methods:** 114 first division football players and 80 second division football players of the Spanish Football League underwent a maximal ergospirometry test, including a 3 minutes-long recovery phase. The alpha signification level was 0,05. **Results:** significant differences on oxygen uptake (p: 0,008) and heart rate (p: 0,024) were found out at recovery phase between players of both categories. No significant difference was found on ventilation (p: 0,055). **Discussion:** during the first minute of the recovery phase we found no significant differences between the individuals of both groups, probably because of baroreflex (4). There are differences between the first and third minute of recovery; it might be due to a different training volume and intensity (5). Our whole population sample consists of professional football players, who might probably have similar training loads. According to our findings, first division football players would have a greater recovery capacity. This could explain a greater competitive level in sports where repetitive efforts are needed, regardless of the technical qualities. **Bibliography:** 1. #### EFFECTS OF DIFFERENT TRAINING ON SOME CHARACTERISTICS OF HEART IN FEMALE STUDENTS

HOSSEINI, M.

*ISLAMIC AZAD UNIVERSITY EAST TEHRAN BRANCH*

**Effects of different training on some characteristics of heart in female students** **Introduction:** Regular and long term training causes physiological adaptation of heart that opposite pathological adaptation(1,2). Sharma(2003) studied 623 elite athletes and found that rowers (Concurrent-trained athletes) had greatest left ventricular mass index(3). The aim of this study was to compare the effects of three different training programs on heart of female students. **Method:** 40 untrained female (age: 25 2.5yrs, height: 164 8.2cm, weight: 57.8 14.6kg) Being randomly divided into endurance (E;n=10), resistance (S;n=10), concurrent (SE;n=10) and control (C;n=10) groups. Left ventricular end diastolic dimension (LVEDD), left ventricular end systolic dimension (LVESD), heart - walls thicknesses, left ventricular mass (LVM) and lvm index of subjects measured by echocardiography both at the outset and after 8 weeks of training. The training programs were 8 weeks, 3 times per week. The Endurance training program comprised running at 65% of HR max for 16 minutes per session at first week where the HR reached 80% HR max towards the end of the program. The resistance training program involved performing 2 sets of bench press, squat, pull down and legs curl initially at 50% of 1RM with 10 repetition per set where the intensity reached 80% of 1RM with 3 sets of 6 repetitions per set towards the end of the program. The Concurrent training program included both E and S training requirements. **Result:** LVESD, lvm and lvmI in the (SE) Group and LVEDD in the (SE) and (E) Groups were significantly larger, compared with baseline (P<0.05). One way ANOVA appeared only to be significantly increased in the LVEDD of (SE) Group (P 0.05). **Conclusions:** The data suggest that the nature of concurrent training created these results. Eight weeks of training, however, to be an insufficient stimulus to elicit significant alterations in the heart structure. It is possible that concurrent training be the factor in preventing of some side effects of resistance training on heart. **References** 1. Haykowsky, M, Chan, S, Bhambhani, Y, Bell, G. (1998). #### EVALUATION OF TRAINING EFFECTS BY ECHOCARDIOGRAM

TANAKA, S., YAMAMOTO, S.

*MUKOGAWA WOMEN'S UNIVERSITY*

**Introduction** Echocardiography is the basic and non-invasive method in assessment of cardiac structure and function in elite athletes, so it is used for medical check and studying the training status of athletes. In the previous female study, we reported that carotid flow volume can be used for evaluating training status or level besides IVSd (Inter-ventricular septal end diameter), LVPWd (left ventricular posterior wall diameter) and CO (cardiac output). In this study, we evaluate training effects of changes in IVSd, LVPWd and CO after four months training by using cardiac echocardiogram. **Method** For 15 eighteen years old female college students of basketball players (18.2 (SD:0.4) years old, 166.3 (6.2) cm, 58.4 (5.5)kg), we evaluate posterior wall- thickness ( LVPWd), septal end diameter (IVSd) and CO by digital diagnostic ultrasound device (UF-8700 made in Fukuda Denshi Company). After four months training schedule, we do echocardiogram again,

and we compare changes in LVPWd, IVSd and CO before to after training. ventricle divider (IVSd: Inter-ventricular septal end diastolic dimension) / the left ventricle by ultrasonography Results There were no remarkable changes in height, body weight and %body fat before to after training. However, LVPWd, IVSd and CO were significantly changed before 8.3 (1.1) mm, 7.9 (0.9) mm and 3.5 (0.51) L/min to 9.3 (0.8) mm, 9.4(0.8) mm and 4.1 (1.09) respectively. Discussion The evaluation by non invasive echocardiogram should be of use for training effect of athletes. References TANAKA, S, YAMADA, A, YOTSUMOTO, M et al. ## CHANGE OF LEFT ATRIAL DIMENSION IN FEMALE ADOLESCENT RUNNERS

KINOSHITA, N.1, ISHIDA, H.2, KATSUKAWA, F.2

1: HOSEI UNIVERSITY (TOKYO), 2: KEIO UNIVERSITY (YOKOHAMA)

**Introduction** Left atrial (LA) enlargement is a predictor of atrial fibrillation (Af) in the general population. LA dimension (LAD) increases along with long-term exercise training (1) and several studies suggested that trained athletes were predisposed to Af (2). The data of LA enlargement related to exercise, however, is available only in adult athletes and in a cross-sectional manner. The aim of the study was to investigate the change of LAD in the early phase of athletic career. **Methods** The subjects were Japanese 51 female middle/long distance runners (15-16 y/o) in a competitive high school team with the national level of achievements. Echocardiography, underwater weighing, and maximal exercise tests were performed mostly at the recruitment when they had already had > 3 years of experience as competitive runners, and repeated after 20+/-6 months. They trained nearly every day throughout the period by running at a speed of 12-20 km/hr for totally 200-500 km/month. LAD was indexed for body surface area (LADi). The changes in variables were tested by paired t-test. LAD and LADi were compared with the average of Japanese young untrained females in the literature (3) by Z test ( $p < 0.05$  was considered significant). **Results** Fat free mass (FFM) and VO<sub>2</sub>max significantly increased (38.6 to 40.5 kg and 56.9 to 60.7 ml/kg/min, respectively) with significant decrease in fat% (16.9 to 14.8 %). The baseline LAD and LADi were significantly larger than the established normal data (32.8 vs. 29.0 mm and 22.7 vs. 19.0 mm, respectively). None revealed LAD > 40 mm at any time. LAD and LADi did not change significantly after 20 months of training (32.8 to 33.4 mm and 22.7 to 22.8 mm/m<sup>2</sup>, respectively), while left ventricular mass (LVM) indexed for FFM significantly increased (3.35 to 3.58 g/kg). Fractional shortening, peak A and E wave velocities, and deceleration time were normal on both occasions and did not differ from each other (37 vs. 37 %, 42 vs. 40 cm/s, 100 vs. 97 cm/s, and 149 vs. 157 ms, respectively). None developed palpitation or supraventricular tachyarrhythmia. **Discussion** LADi of the high school runners was slightly larger than that of young untrained females at the baseline. Although the subjects trained sufficiently to become leaner with increase in VO<sub>2</sub>max and LVM/FFM in 20 months, further LA enlargement did not develop. In conclusion, the left atrium could be enlarged in the very early stage of athlete's career but the pathological consequences (abnormal/persistent LA enlargement or Af) were not likely to occur along with the high school level of training. **References** 1. ## LEFT VENTRICULAR WALL THICKENING IN HIGHLY POWER AND STRENGTH TRAINED ATHLETES

ÇINA, R.

UNIVERSITETI I SPORTEVE TIRANE

Dr. Robert Çina1, Dr. Dhimitraq Prifti1, Msc. Altin Erindi,1 Dr. Tatjana Nurka, Dr. Meri Gjinushi 2 IUST (Tirana, Albania), 2UT, (Tirana, Albania) **Introduction:** It is demonstrated that the cardiac hypertrophy of the trained athlete is a normal response to the physiologic demand during increased physical activity. The evaluation of different morphological parameters of the CV system is used in sports medicine practice to evaluate the progress of training process. **Methods:** 14 track and field athletes (TFA) (short distance runners, throwers and jumpers), 10 weightlifters (WL) and 15 physical education students (PES) were studied. BSA was calculated according to Dubois&Dubois and through standard ultrasound records TDD, IVS and PW were measured. TDV and LV muscular mass (LVMM) was calculated.1 All the ultrasound findings and calculations were normalized with BSA. Means and SD were calculated for all the data and two tailed Student test between the sport groups and control group was performed. **Results and Discussion:** Mean values of both PW and IVS were significantly higher at the sport groups comparing to the PES ( $p < 0.001$ ), WL having the higher values. We found the same results for the BSA normalized values. IVS/PW ratio was similar for all the groups (1.1) and was below 1.3, showing symmetric LV hypertrophy. LVMM was significantly greater to the WL and TFA groups comparing to the PES ( $283.16 \pm 31.98$  and  $300.29 \pm 45.16$  versus  $223.84 \pm 41.29$  gr.  $p < 0.001$ ). Similar differences were found for the LVMM index (LVMM/BSA). LVMM index correlated well with LV wall thickness (IVS  $r = 0.76$  PW  $r = 0.8$ ). LVMM/LVW ratio is calculated as well. The greater values were found at the WL ( $2.36 \pm 0.31$  gr/ml) and TFA ( $2.01 \pm 0.24$  gr/ml), PES values were  $1.75 \pm 0.17$  ( $p < 0.01$  and respectively  $p < 0.01$ ). **Conclusions:** LV hypertrophy with increase of LVMM, as a result of IVS and PW thickening was found as a result of power training. Thickness of the IVS and PW is at the upper physiological normal limit and shows significant changes compared with the control group. LV hypertrophy is symmetrical and can be considered as a physiological response to intermittent intraventricular high pressure during training. **References** 1. ## THE CARDIAC EFFECTS ON WHO BEGAN EXERCISE IN ADULT AGES

KNEFFEL, Z., TRÁJER, E., BOSNYÁK, E., VARGA-PINTÉR, B., MAJOR, Z., KOMKA, Z., PAVLIK, G., TÓTH, M.

SEMMELEI UNIVERSITY FACULTY OF P.E. AND SPORT SCIENCES

**Introduction:** Both in the endurance performance and in the primer prevention it is a very important question how do characteristic features of the athlete's heart develop if regular workouts began not in the childhood but in the adult age. **Methods:** The following echocardiography data were measured by 2D-guided M-mode, Doppler-recordings, and TDI, left ventricle wall thickness, left ventricle muscle mass, left ventricle internal diameter, E/A, E'/A'. **Subjects:** Group "A" contains who have began regular physical training in adult age (later

than 18 yr.) group "Y" started their sports activity in their younger age (elite vs. non-elite athletes) and non-athletic healthy subjects (altogether N=617). Results: Characteristics of the left ventricular hypertrophy (wall thickness/BSA<sup>1/2</sup>, muscle mass /BSA<sup>3/2</sup>) and training-bradycardia developed something less in group "A" than in group "Y". The effect of regular physical training to diminish age-related impairment of diastolic function manifested stronger in the group "Y", although the difference between the two athletic groups decreased in the oldest age range. In female differences between group "A" and group "Y" were higher in all parameters than in the males. Conclusions: Our results indicate that regular physical training started in the young age develop more markedly the characteristics of the athlete's heart, but to begin regular physical activity in the adult age is also useful.

### TESTING RISK FACTORS FOR ARRYTHMIAS IN ELIT ATHLETES

KOMKA, ZS., BOSNYÁK, E., KNEFFEL, ZS., MAJOR, ZS., TRÁJER, E., UDVARDY, A., PROTZNER, A., SZENDREI, B., PAVLIK, G., TÓTH, M.

SEMMELEWIS UNIVERSITY FACULTY OF PHYSICAL EDUCATION AND SPORT SCIENCES

Introduction: Sudden cardiac death of athletes is very rare but it is still 2 to 4 times more frequent than that of the gender- and age-matched normal population. The reasons of the sudden cardiac death in athletes are mostly unclear. Lots of risk factors are well known and it is supposed to relates to repolarization abnormalities. These may be caused by morphological abnormalities and vegetative disfunctions (increased sympathetic activity). Aime: Our aime was to investigate this risk factors related to arrhythmias and describe the results in Hungarian elit athletes compared to non-trained healthy controls. Methodes: 90 elite athletes (56 men (23 triathletes, 11 soccer, 16 handball players, 6 judo); 34 women (11 triathletes, 6 judo, 17 waterpolo players); mean age 23,29±4,5 years) and 24 non-trained control person (12 men, 12 women, mean age 23,36±2 years) took part in our study. Everybody was examined by echocardiography. We analysed the ECG parameters, the frequency range heart rate variability with a special ECG software (Human Cardiosys, Experimetria Ltd) which can be the markers of the myocardial repolarisation's instability (QT-period, QT-dispersion, short term variability of QT and RR (STVQT, STVRR), very low frequency (VLF), low frequency (LF), high frequency (HF), LF/HF). At the same time we took blood samples and analysed the serum levels of epinephrin (A), norepinephrin (NA), dopamin (D) angiotensinogen (AT) and cortisol (C) with ELISA. Results: The athletes have bigger interventricular septum and posterior wall thickness and left ventricular muscle mass compared to the controls (IVSs 15±2,4 to 13,8±1,5; IVSd 10±1,7 to 9,8±1,2; LVPWs 16±1,9 to 14±2; LVPWd 10±1 to 9,2±1; LVMM 239±53 to 205±51). The heart rate variability parameters showed dominant parasympathetic tone in athletes, but the levels of NA, D and AT were higher (HF 30±10 to 21±9; LF 21±5 to 28±8; LF/HF 0,85±0,4 to 1,8±1; A 48±25 to 59,9±19; NA 280±98 to 239±65; D 27±17 to 7,4±3; AT 4±1,5 to 3,4±0,5). The cortisol level was similar in the two groups. The repolarisation's instability parameters were significantly higher in the athletes (QT-dispersion 35±9 to 18,9±3,7; STVQT 5±1,8 to 3,8±1; STVRR 52±26 to 27,8±10). Conclusion: We found healthy athlete hearts without morphological abnormalities. But the markers of the myocardial repolarisation's instability were significantly higher in the athletes and some peptides were also elevated. Some athletes have extremely increased values compared to the other athletes and controls. Probably they must be on the focus and need to have more examinations.

### NEW CRITERIA PROPOSAL FOR T-WAVE POSITIVITY AND QRS COMPLEX MEASUREMENTS

GÓMEZ-PUERTO, J.R., VIANA, B., RIVILLA, M.L., ROMO, E., VAAMONDE, D., DA SILVA-GRIGOLETTO, M.E.

JUNTA DE ANDALUCIA

Introduction Sudden death in athletes presents great social and medical repercussion. Thus, most specialists in sports medicine advice the use of ECG under rest conditions as a pre-competition screening method which allows us to know multiple electrocardiographic variants in sportsmen. T wave alterations and electrocardiographic changes associated to ventricular hypertrophy affecting the QRS should be studied more in depth, since some controversies do exist. Thus, the objective of this study was to assess in detail measurements of QRS complex and T wave in sportsmen and propose new assessment criteria. Methods A cross-sectional study was performed to assess ECG findings under rest conditions in 1200 athletes of both sexes (M: 71.2%, F: 28.8%) in a regional Sports Medicine Center (period: 2006-2010). All participants were federated, and practitioners of different sports modalities, with different performance level and dedication. ECG was performed following the standard technique with a 12-lead ECG. For the QRS complex, the following measurement and analysis criteria were followed: a) Sokolow-Lyon index (1949), b) Kannel et al. criteria (1970), c) SV1,2,3 + RV4,5,6 ≥ 48mm (our measure proposal). With regards to T wave, the following criteria were used: a) Corrado et al. (2005), b) Corrado and McKenna (2007), c) flat-tened or inverted T waves in three or more consecutive leads (our proposal). The QRS complex and T-wave measure criteria proposed in this study were based on pilot studies contrasted with echocardiography performed in our center. Results For the QRS complex, the mean global percentage of left ventricular growth depended on the voltage criteria used (a: 33.7%; b: 54.4%; c: 25.7%, respectively). In all cases, prevalence was significantly higher in males (p<0.05). None of the used criteria showed significant differences in the prevalence of children compared to adults. The greatest prevalence of T-wave alterations was observed with the Corrado et al. criterion (32.4%), followed by that of Corrado and McKenna (18.3%); however, it was the lowest when using the criteria proposed in this study (11.3%). Discussion Since literature shows high discrepancy in the criteria with regards to voltage modifications, the possible abnormality in T waves, and their scarce association with ventricular hypertrophy, new criteria are proposed in the present study for measuring and analyzing the QRS complex and the T wave in a population of athletes. ### LONG-TERM HOLTER ECG MONITORING OF PROFESSIONAL CYCLISTS

CRUZ-CAMPOS, J., CRUZ-MÁRQUEZ, J., CRUZ-CAMPOS, A., CUETO-MARTÍN, B., CAMPOS-BLASCO, T., GARCÍA-JIMÉNEZ, M., GARCÍA-MÁRMOL, E., GRANERO-GIL, P.

UNIVERSITY OF GRANADA

The resting ECG can detect many cardiac abnormalities, but high levels of training to which athletes are subjected can trigger episodes of abnormal heart function, which should be evaluated by means of long-term records. • Objective: The purpose of the study was to detect the frequency and nature of rhythmic alterations in professional cyclists during the late recovery period following a race (average distance= 196,35 km). • Design: A retrospective study involving 22 professional cyclist, volunteers, from 22-34 years old (mean: 26.7 ± 3.4 years), members of a Professional Cyclist team. All were declared fit for cycling and had no ECG abnormalities. Underwent Holter ECG records before and immediately after a race. The Holter used was NORAV DXP-1000 model. • Setting: Interventions: Both the day before

and after a race, the cyclists did not train but did all work or academic activities normally. They were instructed to record their times of sleep and activity. Dependent variables: Pertaining to heart rate, rhythm and ST space. Independent Variable: Physical Exercise (match). • Results: The average pre/post-race heart rates were  $42.9 \pm 6.2$  bpm when awake;  $42.1 \pm 3.4$  ( $p < 0.01$ ) and  $44.6 \pm 5.7$ ;  $41.2 \pm 5.5$  ( $p < 0.01$ ) when sleeping. Both before and after the race, 20 players (92 %) had a mild or pronounced respiratory sinus arrhythmia. Isolated atrial or ventricular premature contractions were observed in 2 (8.3 %), first-degree intermittent A-V blocks and second-degree A-V blocks with Wenckebach periods were observed in 1, high T-waves were found in 10 (42 %), and high take-off of ST segments were found in 16 (72.2 %). • Conclusions: After the match, there are fewer pulsations recorded, there are more bradycardic rhythms and there are fewer arrhythmic events.

#### ELECTROCARDIOGRAPHIC PROFILE OF SPORTS TEAM

CRUZ-CAMPOS, J., CRUZ-MÁRQUEZ, J., CRUZ-CAMPOS, A., CUETO-MARTÍN, B., CAMPOS-BLASCO, T., GARCÍA-JIMÉNEZ, M., GRANERO-GIL, P.

UNIVERSITY OF GRANADA

The 12-lead electrocardiogram (ECG) is not only necessary for diagnosing the sports aptitude of players, but it also provides information on their training condition and cardiovascular adaptations to exercise. • Objective: To determine the electrocardiographic adaptations of sports team (Honor Division volleyball players, 2nd Div. football, ACB basketball, 2nd Div handball and 2nd Div rugby) and relate them to their level of training. • Design: Retrospective study over the course of 18 years, from 1992 to 2009. We analyzed the ECGs taken at the start of each season as part of routine medical test. We analyzed 2,255 ECGs. Setting, context, participants. Male and female youth and Honor Division teams from the same club. 180 women (94 youth, 86 senior) and 352 men (94 youth, 258 senior) (mean age, height, weight) • Intervention: In August-September of each season, a resting ECG was taken for each player to determine pre-competitive fitness. Independent variables: sex, age, years of training. Dependent variables: P waves, QRS, T in duration and voltage and ECG evaluation (axes) • Results: ECG / player Average:  $5.6 \pm 1.9$ , FC resting:  $66.3 \pm 3$  bpm. Left ventricular hypertrophy:  $38.95\% \pm 8.9$ ; Right ventricular hypertrophy:  $12.77\% \pm 3.4$ . Right Bundle Branch Block:  $25.64\% \pm 8.3$ . Participants who required echocardiography: 32 players: ST segment depression. 12 players: Inverted or flattened T wave in two or more leads. 7 men and 4 women: Corrected QT interval prolongation in heart rate (QTc)  $> 0.44$  s in men and  $> 0.46$  s in women. Echocardiography ruled out organic disease. There were no differences in terms of years of training or level. • Conclusions: Electrocardiographic adaptations are similar to those in the literature for team sports. There was no pathological study and all were declared fit for the high-level sport.

#### EFFECTS OF ROUTINE CYCLING TRAINING ON RELEASE OF BLOOD CARDIAC TROPONIN I IN TRAINED ADOLESCENT CYCLISTS

NIE, J., TONG, T., LIN, H., SHI, Q.

MACAO POLYTECHNIC INSTITUTE

EFFECTS OF ROUTINE CYCLING TRAINING ON RELEASE OF BLOOD CARDIAC TROPONIN I IN TRAINED ADOLESCENT CYCLISTS Jinlei, Nie.1, Tom, Tong.2, Hua, Lin.3, Qingde, Shi.1 1: Macao Polytechnic Institute (Macao, China). 2: Hong Kong Baptist University (Hong Kong, China). 3: Liaoning Normal University (Dalian, China) Introduction It has been reported that endurance exercise could lead to a transient and minor increase in biomarkers of cardiomyocyte insult such as blood cardiac troponins (cTn) in adults (Shave et al., 2007). However, there is a dearth of research on this subject in adolescents. Road bicycle racing is one of most popular sports in the world with cyclist populations ranged from adolescents to old adults. Cycling training program is usually composed of repeated bouts of high-intensity sprint (HI) and endurance workout at moderate intensity (END). This study was to examine the release of blood cardiac troponin I (cTnI) subsequent to the two types of routine training in trained adolescent cyclists. Methods Whole blood cTnI was assessed using a two-site enzyme-linked immunosorbent assay (i-STAT analyzer, Abbott, USA) in 12 adolescent cyclists (age:  $16.4 \pm 1.5$  years; height:  $178 \pm 5$  cm; weight:  $71 \pm 4$  kg; training period:  $2.9 \pm 1.3$  years; training volume: 100-200 km/wk) four hours after the HI and END training in two separated days. The HI training consisted of three bouts of all-out uphill 900-m cycling on mountain road (~3 min for each bout) with recovery downhill cycling at the same route (~3 min for each recovery); END was a 60-min continuous constant-load cycling at moderate intensity on a stationary bicycle. Results The blood cTnI levels in four of the twelve subjects after the END training [(Median) 0.015 ng/ml; (Range) 0-0.08 ng/ml] were above the cutoff of 0.03 ng/ml for myocardial injury. However, no cyclists in HI [(Median) 0.01 ng/ml; (Range) 0-0.03 ng/ml] displayed values exceeding the cutoff. Discussion It was found in the present study that four of the twelve trained adolescent cyclists who completed an endurance-type workout in a routine cycling training program were with positive serum cTnI that exceeded the myocardial injury cutoff. The findings are in agreement with our previous report that a single endurance workout would cause elevations of serum biomarkers of myocardial damage in trained adolescent athletes (Nie et al., In Press). In addition, the current findings also indicate that the release of cTnI in trained adolescent cyclists during routine cycling training is dependent of training mode. These provide further information about trends in the biochemical markers of myocardial injury in adolescent cyclists during training that physicians may find useful in the 'routine' clinical evaluation. ### PP-PM12 Vibration Training

#### THE EFFECTS OF ADDING DIFFERENT WHOLE BODY VIBRATION FREQUENCIES TO PRECONDITIONING EXERCISE ON SUBSEQUENT SPRINT PERFORMANCE

ELLEFSSEN, S., RØNNESTAD, B.R.

LILLEHAMMER UNIVERSITY COLLEGE

The phenomenon postactivation potentiation (PAP) can possibly be used to acutely improve sprint performance. Two recent studies have investigated the additional effect of adding whole body vibration (WBV) to PAP-exercises (1, 2). Although both studies failed to find an

ergogenic effect of WBV, it does not seem appropriate to abandon the WBV-approach as a potential mean for performance enhancement. The apparent lack of effects may be due to the distinct features of the applied protocols. Accordingly, we aimed to investigate the effect of adding whole body vibration (WBV) to body-loaded half-squats, performed as preconditioning activity to 40 m sprint test. Nine male amateur soccer players performed one familiarization session and six separate test sessions. Each session included a standardized warm-up followed by one of the following preconditioning exercises; 30 s of half-squats with WBV at either 50 Hz or 30 Hz, or half-squats without WBV. The 40 m sprint was performed one minute after the preconditioning exercise. For each subject, each of the three protocols was repeated twice on separate days in a randomized order. Mean values were used in the statistical analysis. Performing the preconditioning exercise with WBV at a frequency of 50 Hz resulted in superior 40 m sprint performance compared to preconditioning exercise without WBV ( $5.48 \pm 0.19$  s vs.  $5.52 \pm 0.21$  s, respectively,  $p < 0.05$ ). There was no difference between preconditioning exercise with WBV at a frequency of 30 Hz and no WBV condition. In conclusion, preconditioning exercise performed with WBV at 50 Hz seems to enhance 40 m sprint performance in recreationally trained soccer players. The present findings suggest that coaches can incorporate such exercise into the warm-up to improve sprint performance or the quality of the sprint training. 1. J. D. Guggenheimer, D. C. Dickin, G. ### **INFLUENCE OF SIX WEEKS WHOLE-BODY VIBRATION EXERCISE ON ARTERIAL STIFFNESS IN THE ELDERLY**

CHEN, K.W.C.1, CHEN, W.C.2, CHIA, P.S.3, CHI, S.F.4, YE, J.Y.5, WANG, S.W.

CHANG GUNG INSTITUTE OF TECHNOLOGY

**Introduction** Whole body vibration (WBV) recent work has suggested that low amplitude, low frequency mechanical stimulation of the human body is a safe and effective way to exercise musculoskeletal structures and possible beneficial to the cardiovascular system. However, there is no study about WBV training on the elderly arterial function. So, the aim of this study was to analyse the influence of six weeks WBV training on arterial stiffness in the elderly. **Methods** To determine the six weeks WBV training effect on the elderly arterial stiffness which including three test : an arterial stiffness index (ASI) measurement (CardioVision MS-2000; USA) , six minutes walking and blood biomarker. 24 healthy elderly people were volunteered to participate in this study. Elderly people were performed in standing position on a BodyGreen whole vertical vibratory machine ( Taiwan ) for 3 times in a week. We analyze the data before 6 weeks WBV training and after the training for using Paired Samples T-test. **Results** After 6 weeks WBV exercise program, the blood pressure ( systolic pressure:  $146.4 \pm 4.8$  mmHg  $\rightarrow$   $130.3 \pm 4.7$  mmHg , diastolic pressure:  $80.5 \pm 2.6$  mmHg  $\rightarrow$   $74.1 \pm 1.5$  mmHg and pulse pressure:  $73.8 \pm 3.4$  mmHg  $\rightarrow$   $61.6 \pm 3.2$  mmHg), biomarker NO concentration:  $11.4 \pm 1.6 \mu\text{M}$   $\rightarrow$   $16.5 \pm 2.3 \mu\text{M}$  , the 6 minutes walking distance (  $382.2 \pm 23.9$  meter  $\rightarrow$   $425 \pm 20.2$  meter ) were significantly improved ( $p < 0.05$ ). And the inflammatory condition was no difference ( IL-6 and TNF- $\alpha$ ), even more the muscle was no damage (CK activity was no difference) before and after 6 weeks WBV training. **Discussion** Exercise can attenuate large artery stiffness in elderly people (Otsuki et al.2007). In our study, we found that WBV can significant lower ( $p < 0.05$ ) elderly blood pressure. Previous studies demonstrated that arterial remodeling in response to chronic changes in blood flow is endothelium- and NO-dependent (Rudic et al. 1998). Our WBV training increases the production of NO ( $p < 0.05$ ). NO is a potent endothelium-dependent vasodilator and reduces vasoconstrictor response to  $\alpha$ -adrenergic receptor stimulation. So, we think the blood pressure change was due to the increased NO concentration. According to our result, 6 weeks WBV training could be an effective strategy to combat arterial ageing. **References** Otsuki, T., Maeda, S., Iemitsu, M., Saito, Y., Tanimura, Y., Ajsaka, R. & Miyauchi, T. ### **EFFECTS OF BRIEF WHOLE-BODY VIBRATION ON BONE MINERAL DENSITY AND BONE TURNOVER MARKERS IN THE RAT**

NOWAK, A., PAWLAK, M., CELICHOWSKI, J., KRUTKI, P.

UNIVERSITY SCHOOL OF PHYSICAL EDUCATION

**Introduction** Numerous studies have demonstrated the bone mass and strength benefits under the whole-body vibration programs based on high-frequency parameters. The goal of this study was to answer two questions: 1/ if the short-lasting vibration program is adequate for inducing bone tissue response and 2/ if the increased volume of a whole-body vibration modulates the metabolic processes of bone tissue. **Methods** Ten male Wistar rats, aged 6 months, were subjected to a regular 5-weeks whole-body vibration (WBV) program (5 days/week, frequency 50 Hz, amplitude of oscillations 2.5 mm). Results were compared to age-matched controls (n=5). Five animals underwent a vibration training in one session lasting 30 s (group 1) and other five were subjected to four vibration sessions lasting 30 s, separated by 60 s rest intervals (group 2). Before and after the vibration program the total bone mineral density (BMD) was measured using a dual-energy X-ray absorptiometry. After completing the training, the blood was taken from all animals to analyze biochemical parameters: osteocalcin (OC), C-terminal telopeptide of type I collagen (CTX), osteoprotegerin (OPG), receptor activator of nuclear factor (NF)- $\kappa$ B ligand (RANKL). **Results** There were no significant differences with respect to the total BMD values between two terms of the study in both groups of WBV animals. There were no significant differences between both groups of trained animals and the control with respect to concentrations of bone turnover markers, but the tendencies to decreased OC (by 28%) and CTX concentrations (by 15%) were observed in animals from the group 2. The RANKL levels were higher in both WBV groups in comparison to control animals, however, the significant difference was revealed only for animals from the group 1 ( $p < 0.05$ ). **Discussion** The brief whole-body vibration did not influence the BMD values, however, the altered bone turnover was observed after the higher intensity of WBV (4 x 30s). High values of receptor activator of nuclear factor (NF)- $\kappa$ B ligand (RANKL) in WBV groups of animals changed the RANKL/OPG ratio, which is critical to determine bone metabolism. However, the contribution of other tissues in increased serum levels of RANKL could not be excluded.

## EFFECTS OF LONG-TERM WHOLE BODY VIBRATION ON MOTOR UNIT CONTRACTILE PROPERTIES IN THE RAT MUSCLE

KRUTKI, P., ŁOCHYŃSKI, D., KACZMAREK, D., CELICHOWSKI, J.

UNIVERSITY SCHOOL OF PHYSICAL EDUCATION

**Introduction** Whole body vibration (WBV) has been reported to increase activity of motor units (MUs) and these effects are attributed to the enhanced afferent feedback and descending drive to the motoneuronal pool. During WBV high-threshold MUs are more effectively activated due to lower recruitment thresholds of MUs during reflex contractions induced by mechanical tendon vibration in comparison to voluntary contractions. Therefore WBV has been proposed to be a specific training for fast-twitch muscle fibers. We have previously demonstrated that a 5-week WBV indeed induces the considerable increase of twitch and tetanic forces for fast fatigable MUs. The aim of the present study was to determine long-term effects of WBV on MU contractile properties. **Methods** Two groups of Wistar rats were trained on the vibratory platform (Power Plate, USA) for 3 months or 6 months. Each research group underwent four times a day the 30 s vibration (with 60 s intervals), at 50 Hz frequency. The peak-to-peak amplitude of the vibrations was 2.5 mm, and the maximum acceleration of the platform 4.79g. Results were compared to two control groups of normally active rats (matched with respect to age and body weight). Functionally isolated MUs were investigated by electrical stimulation of filaments of the ventral roots of spinal nerves and force recordings from the medial gastrocnemius muscle. MUs were divided into three types: fast fatigable (FF), fast resistant to fatigue (FR) and slow (S). **Results** Changes in proportion of fast MUs were observed after 3 and 6 months of WBV: the increase of a relative number of FF and the decrease of FR units. However, the long-term WBV did not change significantly contractile parameters of FF units, only minor tendencies for an increase of tetanic forces of FF units were found after 3 or 6 months of WBV. On the other hand, there was a significant decrease of the twitch-to-tetanus force ratios in FR and S MUs, due to lower twitch forces and higher tetanic forces in both research groups. **Discussion** Contrary to previously demonstrated effects of force increase observed in FF units after short exposure to WBV, in this study no changes in twitch or tetanic force parameters were found for this type of MUs. This indicates that effects of WBV are temporary in FF MUs, which appear to adapt to a vibration stimulus. On the other hand, the increased proportion of FF units in the muscle after long-term vibration and the fact that the observed changes in MU properties are not restricted to the one type of MUs (but concern FR and S units as well) suggest that the long-term WBV induces deeper processes that influence mechanisms of MU contraction, as altered heavy-chain myosin expression or changed properties of motoneurons.

## ACUTE EFFECTS OF VARIOUS VIBRATION FREQUENCIES ON 1RM IN ELBOW EXTENSORS IN UNTRAINED AND TRAINED SUBJECTS

NYGAARD, H., RØNNESTAD, B.R.

LILLEHAMMER UNIVERSITY COLLEGE

**Acute effects of various vibration frequencies on 1RM in elbow extensors in untrained and trained subjects** Håvard Nygaard and Bent R. Rønnestad Lillehammer University College, Norway **Introduction** A number of studies have previously investigated the effect of mechanical vibration on several different measurements of physical performance. The purpose of this study was to compare the acute effects of superimposed vibration of different frequencies on 1RM performance in the elbow extensors of untrained and recreationally strength trained subjects. **Methods** Eleven untrained ( $\leq 1$  strength training session a week during the previous 6 months) and 10 recreationally strength trained (2-3 sessions of strength training a week during the previous 6 months) subjects participated in the study. The untrained and the recreationally strength trained group were randomly exposed to 30 Hz and 50 Hz of superimposed vibration or control conditions with no vibration, during 1RM tests in triceps pushdown. The vibration (amplitude 2.5 mm) was transmitted through the handle of the training device to the arm muscles. **Results** As a result of 50 Hz of vibration, the untrained group attained an increase in 1RM by 4.9% ( $p=0.013$ ) and 4.5% ( $p=0.014$ ) compared to no vibration and 30 Hz of vibration, respectively. No significant differences between the test conditions were observed in the recreationally strength trained group. **Discussion** The finding of increased 1RM load with vibration of 50 Hz, is in line with previous studies indicating a larger exercise stimulus when vibrations of 45-50 Hz are added to muscle actions with maximal effort, compared to lower vibration frequencies (Hazell et al. 2007; Rønnestad 2009 a & b; Hazell et al. 2010). The increased exercise stimulus is commonly explained by increased activation of the intrafusal muscle spindles that increases the excitatory input to the motoneurons, which in turn is thought to increase the activation of the working muscle and thus increase the force output. This rationale implies that there has to be an activation deficit in the working muscles to achieve an acute increase in force output by adding vibration to the exercise. The latter may explain the lack of effect of vibration in the recreationally strength trained group due to the degree of activation deficit in this coordinative easy exercise. **References** Hazell et al. Appl Physiol Nutr Metab 2007, 32:1156–63 Hazell et al. J Strength Cond Res 2010, 24:1860–5 Rønnestad. J Strength Cond Res 2009a, 23:2068–9 Rønnestad. J Strength Cond Res 2009b, 23:1309–15

## EFFECT OF WHOLE BODY VIBRATION TRAINING PLUS CREATINE SUPPLEMENTATION ON ANAEROBIC PERFORMANCE IN YOUNG VOLLEYBALL PLAYERS

ASLANZADE, F.1, ASLANZADE, A.2, GAIENI, A.2, KOSAR, S.N.3

1:MIDDLE EAST TECHNICAL UNIVERSITY (ANKARA, TURKEY), 2:AIU (TEHRAN, IRAN), 3:HU (ANKARA, TURKEY),

**Introduction** Whole body vibration (WBV) training (1) and creatine supplementation (CrS) (2,3) methods have been widely used to improve neuromuscular and athletic performance in athletes. Although there are many studies examining the effects of WBV training or CrS on athletic performance there is no study investigating the effect of WBV training plus CrS. Therefore, the purpose of this study was to determine the interaction effect of WBV training plus CrS on anaerobic performance (AP) in athletes. **Method** Forty trained male volleyball players (age:  $17.77 \pm 1.03$  y) were randomly assigned to four groups: Cr supplementation (Cr;  $n=10$ ), WBV training (V;  $n=10$ ), WBV training plus Cr supplementation (VCr;  $n=10$ ), or placebo (P;  $n=10$ ). Groups V and VCr were subjected to the WBV training daily for 7 days (5 sets of vertical sinusoidal vibrations lasting up to 100s each, for 8min daily, with a resting period of 30s to 45s between the sets). The frequency (30-50Hz) and the duration (50-100s) of vibration treatment have been increased progressively throughout the study. Groups Cr and VCr were supplemented with Cr monohydrate (4x5g/day) in a double-blind fashion. Group P was provided with an equivalent volume of placebo. All subjects continued their normal training program throughout the study. Anaerobic performance tests (vertical jump, leg squat and 45m sprint run) were performed at the baseline and at the end of the treatments. Two-way ANOVA (treatmentxtime) was used to analyze the data. **Results** All the three treatments (V, Cr, VCr) enhanced vertical jump and leg squat ( $p<0.05$ ). Significant group differences were found in vertical jump and leg squat ( $p<0.05$ ), VCr group exhibiting the most significant change. In addition, both V and VCr groups exhibited significant improvements in 45m sprint run ( $p<0.05$ ), V group showing the most significant improvement. There was no change in any parameter in P group ( $p>0.05$ ). **Discussion** Findings of the study showed that both WBV training and Cr supplementation

improves anaerobic performance. Interaction of WBV and Cr supplementations resulted in co-increment in vertical jump and leg squat. WBV training improves explosive power of lower limb muscles and speed, and this effect can be intensified by combining with Cr supplementation. In conclusion, a short period of WBV training can be used as a new approach for improving strength and power of lower limb muscles by itself alone or beside Cr supplementation. ### DOES THE WHOLE BODY VIBRATION ALTER MUSCLE ENERGY METABOLISM?

URECZKY, D., TIHANYI, J.

SEMMELEWEIS UNIVERSITY

**Introduction** It is well-known fact that whole body vibration results in acute residual enhancement of force generation and physical performance that is believed to be the consequence of neuromuscular and hormonal facilitation. In fact the EMG activity is elevated during vibration beyond a certain frequency. If EMG activity of a muscle is elevated than the muscle tension should also increase which may cause alteration of the content or ratio of the high energy phosphates. Up to now there is only one study investigating the effect of mechanical vibration on muscle metabolism using 20 Hz (Zange et al. 2009). They reported no significant change. Since it was reported that EMG activity is enhanced at higher frequency than 20 Hz (DiGiminiani et al. 2010). We aimed to investigate if 40 Hz vibration frequency might have specific alteration in muscle energetics due to the neuromuscular facilitation. **Methods** Fifteen trained person (7 female and 8 male) participated in this study (age: 19,8±0,77 years, Bw:69,6±9,09 kg, Bh:176,2±7,23 cm). Five subjects received 6x1 minute 20 Hz then 6x1 minute 40 Hz vibration standing in half squat position on a vibrating device (Nemes Bosco). Five subjects received similar treatment, but with 40 Hz first then 20 Hz. Five subjects served for control standing on the device in the same position without vibration. Before vibration, between the two vibration sets and after the intervention inorganic phosphate (Pi), ATP, creatine phosphate (PCr) and Pi/PCr ratio was determined using a 31P magnetic resonance spectroscopy (Philips Achieva 3.0T). **Results** The amount of inorganic phosphate (Pi) decreased in the vibration group, and also in the control group, there was no significant difference between the groups. The peak of creatin phosphate (PCr) and ATP were not change during the trainings. The ratio of the Pi/PCr changed similar than Pi. These change were significant, but there were no difference between the groups. **Discussion** After vibration Pi was depressed in all groups indicated that the change could be attributed to static squat position than to the vibration intervention. Because PCr and ATP remained unchanged the vibration did not resulted in muscle fatigue despite the increased muscle tension. It seems that the increased acute residual physical performance after vibration can be attributed neural facilitation may be in both motor cortex and level. **References** Zange J, Haller T, Müller K, Liphardt A, Mester J. 2009. *Eur J Appl Physiol* 105: 265 - 270. ### EFFECTS OF WHOLE-BODY VIBRATION ON THIGH NEUROMUSCULAR ACTIVITY

RAIMUNDO, A., MALTA, J., BATALHA, N., FERNANDES, O., TOMAS-CARUS, P.

UNIVERSITY OF ÉVORA

**EFFECTS OF WHOLE-BODY VIBRATION ON THIGH NEUROMUSCULAR ACTIVITY** Raimundo,A. 1,2, Malta, J1.Batalha, N.1, Fernandes,O.1,2, Tomas-Carus,P.1,2 1:University of Évora, Portugal, 2:Health Science and Technology Research Centre. **Introduction** The use of whole-body vibration (WBV) appears to influence in a positive way the performance of athletes in certain characteristics such as muscular strength, power and body balance. The aim of this study was to compare the acute neuromuscular activity caused by different vibration frequencies (15Hz and 25Hz), and different knee flexion angles (120° and 150°). **Methods** A total of 19 male university students underwent 4 sessions of WBV. The subjects were exposed randomly to four different WBV protocols using a vibration platform (Galileu 2000). The amplitude allowed by the vibration platform was (peak-to-peak) 3 mm. Each vibration session lasted 6 min and they accomplish a rest period of one day between sessions. The protocols used were: 15 Hz of vibration and 120° of knee flexion; 15 Hz and 150°; 25 Hz and 120°; and 25 Hz and 150°. Muscle activity exerted by the muscles Vastus Intermedius (VI), Vastus Lateralis (VL), Vastus Medialis (VM) and Biceps Femoris (BF) were evaluated by electromyographic analysis (Biopac MP 100, Biopac Systems Inc. Goleta, CA, EUA). Paired Samples T test with repeated measures was used to compare the main effects of muscle activity of each test. **Results** When comparing the two angles of knee flexion (120° vs 150°) with the 15Hz frequency, it was found a different EMG response of the VI (P=0,01), VL (P=0,00), VM (P=0,001) and BF (P=0,02) muscles. Conversely, when it was applied a 25Hz frequency, the angles of knee flexion showed no significant changes on neuromuscular response. Considering the two frequencies of vibration, the neuromuscular response showed significant differences in VI (P=0,046), VL (P=0,036), VM (P=0,028) e BF (P=0,025) muscles, only with 150° of knee flexion. **Discussion** The results of the present study suggest that in this specific position the increase on vibration frequencies, induce an increased on EMG activity on leg muscles. Similar results were observed by Hazell et col (2007). As suggest by Cardinale and Lim (2003), vibrations-induced increases in EMG activity and the consequent degree of motor unit synchronization have been shown to be dependent on the vibration frequency. It was concluded that exposing young people to low – frequency vibration, the neuromuscular activation decreases when increasing the degree of knee flexion. However, when using a degree of knee flexion of 150°, the electromyographic activity increases with the increasing frequency of vibration, more specifically, when increasing the vibration frequency from 15Hz to 25Hz. **References** 1. Hazel T.J., Jakobi J.M., Kenno K.A. (2007). *Appl. Physiol. Nutr. Metab.* 32: 1156-1163; 2. Cardinale M, Lim J. (2003) *Journal of Strength and Conditioning Research.* 17(3), 621–624

### EFFECT OF 6 WEEKS OF VIBRATION TRAINING ON BODY COMPOSITION, STRENGTH AND POWER, VARYING THE MECHANICAL AMPLITUDE AND FREQUENCY OF TRAINING

ROMERO-ARENAS, S.1, MARTÍNEZ, E.1, MANZANARES, A.1, FERRAGUT, C.1, VILA, H.1, ALCARAZ, P.E.1

IUCAM (MURCIA, SPAIN).

**Introduction:** Strength, power and muscular mass are important components of health and physical condition. The vibrations transmitted to the whole body (WBV) are a method that potentially consumes less time to achieve a physical conditioning. But, vibration protocols to maximize the production of strength, power and increase of muscular mass have not still been defined. The aims of the study were to value the effects of: 1) two different amplitudes of vibration (4 mm y 6 mm); and 2) the variation of the weekly training frequency on strength, power and body composition. **Methods:** 52 participants recreationally actives (20.9 ± 3.5 years) took part in the study. Participants were divided in three experimental groups and a control (GC). The experimental groups realized an incremental vibratory training

during 6 weeks starting with 8 sets per session, and increasing one set every week. Frequency of vibration (50 Hz), time of work (60 s) and time of rest (60 s) were constant for the three groups. The first group (GL2) worked with amplitude of 4 mm, 2 days for week; the second group (GH2) worked with amplitude of 6 mm, 2 days for week; and the third group (GH3) worked with amplitude of 6 mm, 3 days for week. All participants were on the platform with the same static position. The maximum isokinetic force ( $60^{\circ}\cdot s^{-1}$  and  $270^{\circ}\cdot s^{-1}$ ) was evaluated at the beginning and at the end of the process. It was also evaluated: the corporal composition by densitometry and the performance in vertical jumps (SJ y CMJ). A repeated measures ANOVA was used to observe the effect of time, and a one-way ANOVA to establish differences between groups ( $p \leq 0.05$ ). Results: A significant increase of isokinetic strength was observed in the experimental groups for the angular velocity of  $60^{\circ}\cdot s^{-1}$  and  $270^{\circ}\cdot s^{-1}$ . Total fat free mass was increased in the groups GH2 ( $0.9 \pm 1.0$  Kg) and GH3 ( $1.5 \pm 0.7$  Kg), being established statistically significant differences among GH3 and GL2 ( $p = 0.02$ ), and among GH3 and GC ( $p = 0.05$ ). No changes were observed when the performance of the jumps was valuated in neither group. Discussion: The results seem to indicate that there is an improvement in the dynamic maximum strength and the explosive force in the muscles extensors of the knee. This is probably due mainly to an increase of the muscular mass. The power of the vertical jump did not improve in any of the groups submitted to study. This absence of improvement may be explained because of an unspecific transmission of vibration, which could interfere in the coordination needed to make activities such as the vertical jump (Fernández-Río et al., 2010). ### PP-PM14 Physiology: Performance in Sport

#### 'THE EFFECTS OF CHA CHA DANCE TRAINING ON CARDIO-RESPIRATORY PARAMETERS'

SIMSEK, D., UZUNER, K., ERTAN, H.

ANADOLU UNIVERSITY

Introduction Dance as an aerobic exercise is getting more interest not only developing cardio-respiratory performance but also developing flexibility and balance in all ages. In this study, we aimed to evaluate effects of 3 month Latin American 'Cha Cha' (LAD 'Cha Cha') training on anthropometric and cardio-respiratory functions. Methods Individuals between 18–25 ages who are first time started to a dance training programme and dancers who are dancing for 5–9 years ( $x = 7 \pm 0.65$  years). 24 (12 women, 12 men) individuals were divided into 3 groups in the study; group I: Sedanters, group II: Dance training group and group III: Dancer group. Group II and group III were undertaken into LAD 'Cha Cha' training. Anthropometric (body weight, body muscle index (BMI), fat mass (FM), fat free mass (FFM), body fat percent (BF %), total skinfold thickness) and cardio-respiratory (maximal oxygen uptake ( $VO_{2max}$ ), respiratory exchange ratio (R), minute respiration volume (VE), tidal volume (TV), minute respiration number (RR), heart rate (HR), systolic blood pressure (SBP), diastolic blood pressure (DBP)) measurements were taken from the subjects before and after their 3 month training program. Skinfold measurements were done by Holtain brand skinfold caliper with 0,2 mm sensitivity. Exercise measurements were done by Sensormedics Vmax 29C. Anthropometric and cardio-respiratory values before and after 3 month training were compared within and among the groups by using t-test, ANOVA and Post Hoc Test for multiple comparisons if it is applicable. Results In conclusion, sedanter group with similar age and active living conditions but without regular exercise program did not show significant changes in their aerobic capacity. 3 months Cha Cha training both women and men of dance learning (beginner), and dancer groups caused significant progress in their aerobic capacity values measured as  $VO_{2max}$ ,  $R_{max}$ ,  $SBP_{max}$ ,  $HR_{max}$ ,  $HR_{rest}$ , body fat ratio. Discussion It can be stated that sedanter group with similar age and active living conditions but without regular exercise program did not show significant changes in their aerobic capacity. In conclusion, 3 month couple dance training ('Cha Cha') both women and men of dance learning, and dancer groups caused significant progress in their aerobic capacity values ( $p < 0.05$ ). The research findings correspond with those of an earlier study conducted by Schantz and Astrand (2004), Wyon and Redding (2005) supports our findings. References Schantz, PG., Astrand, PO. #### LONG TERM PLANNING IN TRIATHLON: FROM THE BEGINNING TO HIGH PERFORMANCE

RUIZ TENDERO, G.

COMPLUTENSE UNIVERSITY OF MADRID

Ruiz, G. Complutense University (Madrid, Spain). Introduction In a controlled sports system it is necessary to set the stages for long term development. In this way, it would be possible an adequate progression to the highest achievements. Literature often reports different stages models with no empirical method. There are no models for triathlon, a special sport in which athletes come from other endurance disciplines related to triathlon (swimming, cycling and athletics) (Federation Française de Triathlon, 2003-04; Ruiz, Salinero, & Sánchez, 2008). The aim of this study is to establish the long term sports stages for triathlon from empirical data of a high level triathletes' group. Methods A sample of 48 Spanish high level triathletes ( $25.48 \pm 4.92$  years old) has been requested to complete a retrospective questionnaire about their sports career. Results A graphic figure including long term sports stages for triathlon has been created with these data: Starting age in previous discipline-swimming: ( $n = 27$ ):  $7.48 (\pm 2.72)$  Starting age in previous discipline-cycling ( $n = 5$ ):  $12.40 (\pm 4.98)$  Starting age in previous discipline-athletics ( $n = 6$ ):  $13.17 (\pm 4.83)$  Starting age straightforward in triathlon ( $n = 10$ ):  $13.90 (\pm 3.17)$  Starting age in triathlon from other endurance discipline:  $16.66 (\pm 4.5)$  Starting age in triathlon competitions:  $16.23 (\pm 4.29)$ . Starting age in triathlon national competition:  $17.77 (\pm 4.18)$  Starting age in triathlon international competition:  $19.90 (\pm 4.34)$  Achievement age of local/regional success in triathlon:  $17.11 (\pm 4.17)$ . Achievement age of national success in triathlon:  $18.85 (\pm 4.05)$ . Achievement age of international success in triathlon:  $21.29 (\pm 4.26)$ . Years of experience in triathlon:  $9.19 (\pm 4.01)$ . Discussion Starting ages in triathlon ( $16 \pm 4.38$ ) are higher than in other studies with other sports high level athletes: 10,26 years (Hill, McConnell, Tammie, & Moore, 2002) or less than ten years old for 50% of the sample (García Ferrando, 1996). It is necessary to know the real nature of triathlon to understand its evolutionary stages. The sporting past and the continuous flow of athletes are determining these natural periods. ### ANAEROBIC THRESHOLD AND CRITICAL VELOCITY PARAMETERS IN SLALOM KAYAK SPECIFIC TESTS, BEFORE AND AFTER MONITORED TRAINING

MANCHADO-GOBATTO, F.B.1, VIEIRA, N.A.1, MESSIAS, L.H.D.1, TEREZANI, D.1, BORIN, J.P.1, FERRARI, H.G.1, ANDRADE, V.C.1

1:UNIMEP (PIRACICABA, BRAZIL); 2:UNICAMP (CAMPINAS, BRAZIL)

**Introduction** The slalom kayak depends on aerobic and anaerobic conditioning (ZAMPARO et al., 2005). However, this modality shows deficiencies in physiological tests for determining these capacities. The aims of study were suggest a specific anaerobic threshold (AT) test for slalom kayak, comparing their results with the obtained using a non-invasive critical velocity (CV) model and also to verify these responses before and after 7-weeks monitored training. **Methods** Six well trained kayakers (K1) (17±4yrs) were submitted to specific tests on a lake, before and after training program. The AT was determined by a progressive kayak "shuttle" exercise (50-m course, 3min/stage) until exhaustion. The velocities adopted were 5,6,7,8,9 and 9.5Km/h, with blood sample collection after each stage. Individual curves 'intensity vs blood lactate' were plotted and the AT was obtained using visual inspection and intersection of the bi-segmental linear regression. From these tests, the individual total time (TT) between AT and exhaustion were obtained. The CV protocol consisted of 4 maximal exercises paddling at 150, 300, 400 and 600-m, with minimum 1hr rest among them. The slope and y-intercept of linear mathematical model 'distance vs time' were CV and anaerobic paddling capacity (APC), respectively. The training program was accomplished on a lake and river and the intensity sessions were obtained by the individual rating of perceived exertion (RPE). The product of daily volume (min) and RPE was considered the load training (FOSTER et al., 2001). The results were analyzed by t-student test, one-way Anova and Pearson correlation ( $P < 0.05$ ). **Results** The AT and CV were not different in initial tests ( $6.7 \pm 0.2$  and  $6.8 \pm 0.1$  Km/h) and there was not significant correlation among APC and TT. Despite volume training has showed changes, the intensity was not modified during this period and the load reduced only the last week. After program, the AT increased ( $7.3 \pm 0.2$  Km/h) without modified CV ( $6.7 \pm 0.0$  Km/h). APC and TT showed significant correlation ( $r = 0.66$ ). At both moments, the blood lactate at AT was similar ( $2.4 \pm 0.2$  and  $2.6 \pm 0.4$  mM). **Discussion** The AT specific protocol detected aerobic capacity increase after 7-weeks training characterized by small changes intensity and load. The same was not verified with CV and APC. Thus, the invasive protocol seems more appropriate to evaluate the effects of training applied to slalom kayakers. Supported by FAPESP, CAPES and CNPq **References** Foster C, Florhaug JA, Franklin J, Gottschall L, Hrovatin LA, Parker S, Doleshall P, Dodge C. (2001). *J Strength Cond Res*, 15,109-15. ### THE EFFECT OF SAND-BASED TRAINING IN AGILITY OF PREPUBESCENT VOLLEYBALL PLAYERS

GORTSILA, E., THEOS, A., SMIRNIOTI, A., MARIDAKI, M.

UNIVERSITY OF ATHENS

**INTRODUCTION** Agility is believed to be an important physical component, necessary for successful performance in volleyball and recreational activities (1). Beach volleyball is characterized by short fast runs on sand and many vertical jumps and therefore its training consists of sprints and agility exercises on sand surface (1, 2). The purpose of the present study was to examine the effect of a sand-based training program in agility. **METHODS** Fifteen female prepubescent volleyball players (age:  $11.1 \pm 0.6$  yrs, height:  $151.6 \pm 1.8$  cm, weight:  $40.9 \pm 1.7$  kg) took part in this study. Subjects participated in a 10 week training program that included 3 organized court training sessions per week on sand surface. Measurements of agility (T-Test & Illinois test) were conducted before (pre) and after (post) the training period. Agility tests were performed on the land (L condition) and on the sand (S condition) in different days. Differences in agility pre - post training and between the conditions were analysed using T-test. Results are presented as mean  $\pm$  SE. **RESULTS** Agility T-Test differed significantly in both conditions (L and S) pre and post the 10-week training program (L pre:  $15.3 \pm 0.1$  vs. post:  $13.2 \pm 0.1$  sec,  $p < 0.001$  and S pre:  $18.0 \pm 0.1$  vs. post:  $15.0 \pm 0.1$  sec,  $p < 0.001$ ). Performance in Illinois test was significantly improved too (L pre:  $22.2 \pm 0.1$  vs. post:  $20.2 \pm 0.1$  sec,  $p < 0.001$  and S pre:  $23.5 \pm 0.2$  vs. post:  $21.4 \pm 0.2$  sec,  $p < 0.001$ ). Significant differences were also observed in the two conditions in T-Test (pre L:  $15.3 \pm 0.1$  vs. S:  $18.0 \pm 0.1$  sec,  $p < 0.001$  and post L:  $13.2 \pm 0.1$  vs. S:  $15.0 \pm 0.1$  sec,  $p < 0.001$ ) and in Illinois test too (pre L:  $22.2 \pm 0.1$  vs. S:  $23.5 \pm 0.2$  sec,  $p < 0.001$  and post L:  $20.2 \pm 0.1$  vs. S:  $21.4 \pm 0.2$  sec,  $p < 0.001$ ). **DISCUSSION** The results of the present study suggest that a 10-week training program on sand surface can significantly improve agility. Despite the fact that the whole training program was conducted on sand, agility was also improved when tests were performed on land. **REFERENCES** 1. Young, W.B., McDowell, M.H., Scariett, B.J. (2001). Specificity of sprint and agility training methods. *J. Strength Cond. Res.*, 15 (3), 315-9. 2. Bishop, D. (2003). ### PERFORMANCE FACTORS IN THE FIRST SERVE IN EXPERT TENNIS PLAYERS

MENDES, P.C.1, MENDES, R.2, FUENTES, J.P.3, CAMPOS, F.4, MENAYO, R.5, CORBI, F.6, ARAÚJO, D.7

ESCOLA SUPERIOR DE EDUCAÇÃO DE COIMBRA

1: CIDAF (Coimbra – Portugal), 2: CIPER (Lisboa – Portugal), 3: FCD – UEX (Cáceres – Espanha), 4: ESEC (Coimbra – Portugal), 5: FCSAFD (Murcia – Espanha), 6: INEFC (Lleida – Espanha), 7: FMH (Lisboa – Portugal). **Introduction** Tennis is practiced in a competitive frame of great variability and uncertainty, where the player needs to constantly make decisions based on their individual characteristics (morphological, psychological and technical) on the opponent, in the physical environment and tasks. The tennis player's training process influences his performance and should include the three categories above mentioned, which Newell (1986) appointed by the constraints (practitioner, environment and task). This study analyzes the constraints in the tennis match and the coaching methods most valued and used by the tennis competition coaches. **Methods** We conducted a pilot study with twelve Portuguese coaches, twelve English coaches and twelve Spanish coaches. The questionnaire was validated in three languages, Portuguese, English and Spanish, using a scale of verification and validation of the contents of fourteen items and a five-point Likert scale numbered from 1 to 5 (1 - totally disagree and 5 - completely agree). Later, 140 coaches from 31 countries, participated on the study. **Results** A factorial analysis, which, resulted in the acceptance of two factorial structures: constraints on the performance of the serve and on the coaching methods. The coaches considered the coordination, central physical fatigue, self-confidence, concentration, emotional control and motivation very important in the performance of the first serve. **Discussion** Under the Environmental Constraints, wind was the variable that most constrains, in the opinion of coaches, the performance of serve in a competitive context. We conclude that the trend of competition training is for the accuracy, the practice in

conditions that mimic competition, the training of psychological skills on the court and power. The coaches overemphasize the intrinsic factors over the extrinsic factors and the coaching is not directed to the functional motor variability.

### PROFILING FUNCTIONAL PERFORMANCE OF 14-16 YEAR OLD FEMALE VOLLEYBALL PLAYERS

MIRKOV, D., KNEZEVIC, O., JELIC, M., SIKIMIC, M., ILIC, V., NESIC, G.

UNIVERSITY OF BELGRADE FACULTY OF SPORT AND PHYSICAL EDUCATION

Profiling functional performance of 14-16 year old female volleyball players Mirkov D, Knezevic O, Jelic M, Sikimic M, Nesic G. Faculty of Sport and Physical Education, University of Belgrade, Serbia Introduction Profiling athletes is of importance for discerning anthropometric and physical characteristics that may distinguish studied group from other subjects' population (Kukolj et al., 2003). Volleyball is a highly specialized sport, with both anthropometric and physiological characteristics being distinctive at the various competition levels (Duncan et al., 2006). Despite the popularity of volleyball, there is a lack of data related to the player profiles, particularly those that compare young female competitors of different age. The aim of our study was to investigate the anthropometric and physiological characteristics of female adolescent volleyball players and to assess their age-associated differences in selected variables. Method The participants (girls of 14, 15 and 16 years of age - G14, G15 and G16; N=167) were selected from 4 regions in order to make a selection for the national team. They were assessed on a number of anthropometric and physiological variables. Body height (BH) and body fat (%BF) were assessed using surface anthropometry; body weight (BW), upper body power by a medicine ball chest pass (MBCP); leg power using various jumps (long jump, squat and countermovement jump, jump with reaction time), speed by 20m sprint (S20, with lap times at 5 and 15m) and agility by T test (TT). Results Significant differences ( $p < 0.05$ ) were found between groups G15 and G16 for the following variables: BH, BW, %BF, MBCP, TT and S15 and S20. Differences between G14 and G15 were present only for BH and MBCP ( $p < 0.05$ ). There were no differences in physiological variables between groups G14 and G16. When comparison was made between the girls who were afterwards selected for a national team, and those who were not, similar differences were found. The selected girls were significantly higher, and also demonstrated better results in MBCP and TT. There were no significant differences between both the age groups and selection groups in jumping performance (all  $p > 0.05$ ). Conclusion This study evaluated the anthropometric and physiological characteristics of a group of female adolescent volleyball players and provides an insight into these characteristics with respect to age and national team selection. The obtained results suggest that body height, upper body power, and agility are key physical performance characteristics of adolescent girls who play volleyball. These findings could allow coaches and athletes to identify the physical and performance characteristics specific to the age groups for purposes of evaluation, selection, and development. ### SAFETY MEASURES IN GOLF-THE ACTUAL SITUATION CONCERNING ACCIDENTS AS REVEALED BY A QUESTIONNAIRE SURVEY OF GOLF COURSES A POSSIBLE MEASURES TO PREVENT THEM-

YOSHIHARA, S.1, KITA, T.2, YAMAMOTO, T.3, MIURA, M.4, MIURA, K.4, NOGUCHI, K.4, AKITA, K.4, ICHIKAWA, D.4, KATOH, Z.5, REE KYOUG, O.K.6, TAMURA, M.7

1:ST.MARIANNA UNIV.(JAPAN), 2:TEIKYO UNIV. OF SCIENCE(JAPAN), 3:MUSASHINO ART UNIV.(JAPAN), 4:TOYO UNIV.(JAPAN), 5:AICHI MIZUHO COLLEGE(JAPAN), 6:EWHE WOMEN'S UNIV.(KOREA), 7:MEIJI UNIV.(JAPAN)

[Objective] We have identified the actual situation concerning accidents and emergency medical services in golf course in the last time through questionnaire survey we sent to more than 2,200 Japanese golf courses during the 25 years. This time, in order to survey the safety situation in Australia district golf courses, we distributed questionnaires to 392 golf courses in Japan(kinki)district. [Method] The survey period was one year, between April 2008 and March 2009 Six questions posed were as follows: 1).Frequency of ambulances dispatched to the golf courses in a year (subdivided into the number of emergency calls per month), Reasons for calling an ambulance? 2). Established cooperative arrangement with neighboring hospitals (general and private hospitals)? Distance to recommended hospital departments and travel time? 3). Emergency medical care available at the golf course and crisis control system (designated person in charge, emergency training, qualified first aid persons, emergency equipment, fixtures, etc.), 4), Annual incidence or accidents among golfers (surgical accidents, deaths, etc)? [Results] 1) 「Ambulance calls」 : Out of 392golf courses,63 replied. The response rate was 16%. With respect to the month, there 11requests in January (17.4%), 9 in February (14.2%), 16 in March (17.2%), 14 in April (22.2%), 27 in May (42.8%), 7 in June (11.1%), 47 in July (65.0%), 19 in August (30.1 %), 6 in September (27%), 12 in October (19.0%), 9 in November (14.2%), 2in December (3.1%), respectively These results indicated that ambulance calls were most frequent in July and June in all regions Emergency medical care system: Concerning emergency medical care procedures at golf courses,14 golf courses(22.5%) said that "cooperative arrangements with a given medical institution are in place", while 49 courses (77.7%) replied that they had "no fixed cooperative arrangements". About half of the golf courses did not have an established system for cooperating with a given medical institution in case of an emergency. Looking at practical emergency care procedures in the case of an emergency on the golf courses, 7 golf courses (63.4%), the majority had a designated member of staff who would be expected to take charge.63.4 courses(36.5%) did seventy-seven 35 courses (55.5%) held training courses for their staff in emergency care, but 28 courses (44.4%), the majority, provided no emergency training 3). 「Accidents to golfers」 Accidents to golfers involving golf balls and clubs had been experienced at 36golf courses (57.1 %) and had not been experienced at27 (42.8%). 23 golf courses (47.6%). had experienced accidents due to falls and slips, while 34(53.9%) had not. There were 2 accidents resulting in death at 2 golf courses (3.1%) last year. Since the golf courses had been in operation, there had been 21 fatal accidents in total, 1 of them due to being struck by a thunderbolt (at 3 different courses). ### MOVEMENT STRATEGIES OF TRAMPOLINE JUMPS COMPARED TO STANDARD JUMPS

BUBECK, D., REULE, C., ARNOLD, N., ALT, W.

UNIVERSITY OF STUTTGART

Different materials and properties of the ground as well as different goals of the movement determine the characteristics of a movement in stretch shortening cycle movements. So it is very interesting to have a look at different jump movements dealing with the same goal: jump as high as possible, and analyse their special movement patterns mechanically and from a neuromuscular view. In order to analyse such differences in movement strategies during jumping movements the jumps on a trampoline (TJ) were compared to the movements in squat (SJ), countermovement (CMJ) and drop jumps (DJ). Therefore 9 athletes of the german Olympic competition team (active

and juniors) in trampoline took part in a study. Ground contact times on the trampoline were recorded as described by REULE (2010) and performing the SJ, CMJ and DJ the ground reaction forces were recorded on a Kistler force platform. Surface EMG of 8 main leg muscles were depicted concerning to Seniam. Joint excursions were analyzed using Penny&Giles goniometers at the ankle and knee. Mechanical and neuromuscular data were time synchronized with respect to the takeoff of the jumps. The contact times compared between DJ and TJ reveal similar contact times for both jumps but the correlation between the two jumps was very low ( $r=0.29$ ). Analyzing the jump heights of the different jumps it can be seen, that a high correlation between the SJ, CMJ and DJ on one hand and the TJ on the other hand indicates that the capability to jump high on the trampoline can also be found in the jump performance of SJ, CMJ and DJ. Comparing the activation intensity of the neuromuscular parameters using iEMG data of the depicted muscles between the different jump conditions it can be seen that the main difference is observable in the m. rectus femoris. This muscle is clearly lower activated during the TJ condition. Analyzing the maximal joint excursions with respect to the take off it can be seen that during the TJ clearly lower angles were observable. The moment of the maximal angle was comparable between SJ, CMJ und TJ. Although it can be seen that the jumping performance performing SJ, CMJ and DJ in terms of jumping heights is reliable to the jumping height on the trampoline, this study reveals clearly different activation characteristics between the standard jumps (SJ, CMJ and DJ) and the trampoline jump. So it is questionable if training the standard jumps is the adequate training stimulus for enhancing the jumping performance on the trampoline. These results indicate that from a special point of view the control of the different movements occurs in different ways. So it must be the question of further studies if discriminating all jumps only in the three types of standard jumps is good enough to explain different movement control strategies.

### THE RELATIONSHIP BETWEEN LOWER LIMB POWER AND GOLF DRIVE BALL DISTANCE IN ELITE GOLFERS.

HASLAM, S.J., CLARK, D., HUNTER, A.M.

UNIVERSITY OF STIRLING

THE RELATIONSHIP BETWEEN LOWER LIMB POWER AND GOLF DRIVE BALL DISTANCE IN ELITE GOLFERS. Haslam, S.J.<sup>1,2</sup>, Clark, D.<sup>2</sup>, Hunter, A.M.<sup>1</sup>  
<sup>1</sup>University of Stirling (Stirling, Scotland), <sup>2</sup>SportScotland Institute of Sport (Stirling, Scotland) Introduction Distance achieved in a golf drive directly depends upon the ability of the golfer to transfer the greatest amount of kinetic energy (ground reaction force (GRF)) throughout the body to accumulate at the club head, via a kinetic link sequence (Nesbit and Serrano, 2005). The energy required to produce the large GRF has thought to be a result of the work done by the legs and hips in pushing against the ground (e.g., Hume et al. 2005). In turn, an increased power output from the lower limb would result in a significant increase in club head velocity, and thus striking distance. However, despite the relative importance of increasing lower limb power to enhance striking distance, there is a relative lack of research investigating this relationship, especially for an elite cohort. As a result, the aim of this study was to objectively determine if there is a relationship between lower limb power and distance achieved to a golf drive in elite amateur golfers, by correlating the execution of a counter-movement jump (CMJ) to striking distance and examining the related GRF's. Methods Twenty-seven right-handed elite level golfers; mean age 19.8 (2.4) yrs, mass 74.8 (12.6) kg, height 178.0 (12.6) cm, and handicap 0.26 (2.5), took part in the study, following ethical approval being granted. The study consisted of each participant performing twenty golf drives on a force plate (hitting the ball as far possible) and three maximal CMJ's. The intervention was repeated to allow a measure of reliability. Results There was a significant positive correlation between distance and CMJ height ( $P < 0.01$ ;  $r^2$  0.483). A similar positive relationship was also shown between distance and maximal vertical GRF ( $P < 0.001$ ;  $r^2$  0.593), and mass and distance ( $P < 0.001$ ;  $r^2$  0.679). All variable outcomes of the golf swing and CMJ demonstrated good day-to-day reliability ( $r^2 > 0.80$ ;  $P < 0.001$ ; CV < 5%). Discussion The significance found between distance and CMJ provides convincing evidence that lower limb power is directly related to striking distance. Further evidence for the above statement is also afforded by the positive relationship between maximum vertical GRF and striking distance. A strong positive relationship was also noticed between subjects' mass and distance. However, due to the positive relationship between CMJ and ball distance it is likely that this mass will be proportionately composed of lean efficient tissue (Kawashima et al, 2003). As a consequence, lower limb power, and possibly hypertrophy, training may have performance benefits for elite level golfers. References Hume PA, Keogh J, Reid D. (2005). Sports Med, 35, 429-449. ### GENDER DIFFERENCES IN PHYSIOLOGICAL CHARACTERISTICS OF JUNIOR TENNIS PLAYERS.

GIANNOPOULOS, A., DELIS, D., THEOS, A.

UNIVERSITY OF ATHENS

Introduction Gender differences in aerobic capacity and muscle strength during growth have been studied thoroughly (1, 2). Previous studies have also examined anthropometric and somatotype characteristics of junior tennis players, but not the physiological ones (3). Therefore, the purpose of the present study was to examine the gender differences in physiological characteristics of junior tennis players. Methods 17 male (group M) and 14 female (group F) tennis players (age:  $16.5 \pm 1.2$  vs  $15.1 \pm 0.5$  yrs, height:  $174.1 \pm 2.0$  vs  $164.6 \pm 1.7$  cm, body mass:  $67.4 \pm 3.9$  vs  $55.9 \pm 1.2$  kg, mean  $\pm$  SE) participated in this study. Sit and reach (SR) flexibility test, maximum handgrip strength, agility T-test and 20m shuttle run test (for the prediction of VO<sub>2</sub>max) were measured. Differences between the two groups in VO<sub>2</sub>max, agility T-test, SR and handgrip strength were analyzed using T-Test, while relationships between variables were assessed using the Pearson's product moment correlation coefficient (r). Results are presented as mean  $\pm$  SE. Results VO<sub>2</sub>max differed significantly between groups ( $M = 38.8 \pm 2.7$  vs  $F = 28.6 \pm 1.9$  ml/kg/min,  $p < 0.01$ ) and so did the handgrip strength levels ( $M = 33.1 \pm 2.1$  vs  $F = 24.8 \pm 0.9$  kg of force,  $p < 0.001$ ). On the other hand, group F performed significantly better in SR test compared to group M ( $F = 20.6 \pm 1.6$  vs  $M = 13.1 \pm 2.0$  cm,  $p < 0.01$ ). Furthermore VO<sub>2</sub>max and agility T-test were significantly correlated in group M ( $r = 0.63$ ,  $p < 0.01$ ), but not in group F ( $r = 0.11$ , n.s.). Discussion The results of the present study are inconsistent with previous studies outlining significant gender differences in flexibility, aerobic capacity and muscle strength (1, 2). However further research is needed in the case of tennis players. 1. Pate, RR., Wang, CY., Dowda, M., Farrell, SW., O'Neill, JR. (2006). Cardiorespiratory fitness levels among US youth 12 to 19 years of age: findings from the 1999-2002 National Health and Nutrition Examination Survey. Arch Pediatr Adolesc Med., 160 (10), 1005-1012. 2. ## IMPACT OF PHYSICAL PERFORMANCE ON TENNIS RANKING IN JUNIORS –RESULTS FROM THE NATIONWIDE GERMAN TENNIS TEST

ULBRICHT, A.1, FERRAUTI, A.1, PFANNKOCH, P.2, GEWEHR, J.1, FERNANDEZ-FERNANDEZ, J.1

1: RUHR-UNIVERSITY BOCHUM; 2: GERMAN TENNIS FEDERATION

**Introduction** The German Tennis Test consists of a two times annual physical testing of all 300 junior squad players including basic (e.g. abdominal strength endurance), semispecific (e.g. 10 m sprint) and specific tests (e.g. service velocity). Data feedback is given with individualized training advices. In the present study we compared the physical performance testing results with the positions of all players on the German junior ranking list. This age independent list (under 12 to under 18) includes more than 2000 male and female junior players and the players position depends on the number and quality of tournament match wins. **Methods** 178 boys (m14: n=75, m16: n=63 and m18: n=40) and 105 girls (f14: n=57, f16: n=30, f18: n=18) were tested for biometric data (body height, body weight, BMI, range of arms, skin fold thickness), flexibility (stand and reach, internal and external shoulder rotation), strength (hand grip, push-ups, back extension, crunches), upper body power (medicine ball throw, forehand and backhand side throw, service velocity), speed, agility and jumping ability (10, 20 m linear sprint, counter movement jump, horizontal jump, foot tapping frequency, repetition jump efficiency, tennis specific shuttle sprint) and tennis specific endurance (Hit & Turn Tennis Test (Ferrauti et al. 2011)). Pearson's product moment correlations were calculated between the test results and the German junior tennis ranking for male and female under 14, under 16 and under 18 players. **Results** Service velocity (m14: r=.506, m16: r=.397, m18: r=.558, f14: r=.554, f16: r=.688, f18: r=.314) and medicine ball throw (m14: r=.482, m16: r=.301, m18: r=.333, f14: r=.432, f16: r=.513) showed the highest correlation to the players ranking position. Further significant correlations were found between rankings and the Hit & Turn endurance test performance, especially in females (f16: r=.594), as well as for hand grip force and body height. Semi- and tennis-specific agility, speed and jumping ability were less correlated to the ranking. No correlations were found between basic tests (e.g. core strength endurance) and rankings. **Discussion** Our results underline the importance of the upper body power for junior tennis player's performance. Coaches should concentrate more on the development of these capacities, since in professional tennis the service velocity increased significantly during the last decade (Weber et al. 2010). More research should be focused on the development and evaluation of upper body power intervention programs. **References** Ferrauti A, Kinner V & Fernandez-Fernandez J. (2011). ## PSYCHOBIOLOGICAL MARKERS OF STRENGTH TRAINING IMPACT IN YOUNG TENNIS PLAYERS

SARABIA, J.M., JUAN-RECIO, C., HERNÁNDEZ, H., URBÁN, T., MOYA, M.

SPORTS RESEARCH CENTRE, MIGUEL HERNANDEZ UNIVERSITY OF ELCHE, ALICANTE, SPAIN

**Introduction** Training load individual control and its effect on performance is one of the most important issues nowadays in the field of sport science (Borresen & Lambert, 2009). The aim of this study was to evaluate the individual capacity to respond or adapt to a strength training program based on maintenance of mechanical power rather than an absolute measure of changes in physiological variables that occur with training. **Methods** Ten young male tennis players (mean age: 15.60 ± 0.70) with no experience in strength training programs (STP) took part in this study. The intervention period was 6 weeks (2 d/w) where they worked a bench-press exercise with free weights and semi-squat in the Smith machine (steady load of 60% of the MDS). Before and after the intervention period, the players' upper and lower limb power was direct and indirectly assessed. During the study subjects completed a training diary that included these variables: hours of sleep, morning weight and heart rate, a muscle soreness scale, RPE and POMS. To determine testosterone (T) and cortisol (C) three saliva samples/week were collected, on the same day of the week at different hours: 8:00, 11:00 and 18:00. **Results** Statistical analysis was divided in 2 parts: a related samples t-test to the kinetic and dynamic variables, and an analysis of repeated measures for the biological and psychological training data diary. The t-test revealed that the STP significantly improved the CMJ in 15" (p<.05); maximum acceleration and strength in bench press (p<.01); maximum power, average power of the propulsive phase, and maximum speed in semi-squat (p<.05) and distance reached and output speed with medicine ball (p<.01). Repeated measures analysis showed an increase in muscle soreness (weeks 2-3, p=0.038; F=6,493) in RPE (weeks 3-4, p=0.027; F=7,822) in the tension subscale of POMS (weeks 4-5, p=0.025; F=8,018). Decreases were found in the total score of POMS (weeks 5-6, p=0.014; F=10,500), saliva T at 8.00 (weeks 5-6, p=0.042; F=5,609), saliva T at 11.00 (weeks 5-6, p=0.019; F=8,169) and T average day in saliva (weeks 5-6, p=0.026; F=7,077). There were no significant differences in saliva C. **Discussion** STP based on maintenance of mechanical power with training frequencies of 2 d/w, appear to be appropriate to improve some kinetic and dynamic variables (Legaz-Arrese et al., 2007). Moreover, some biological markers (T) and psychological (muscle soreness, RPE, tension subscale and total score of the POMS) seem to be sensitive to training load changes and record the impact in young tennis players. **References** Borresen J, Lambert M. ## BONE QUALITY OF THE CALCANEUS IN YOUNG FEMALE GYMNASTS TRAINING ON HIGH VERSUS LOW IMPACT LOADING SURFACES

GERRITS, K.H.L., CRINS, M.H.P., VAN DER EB, J., DE HAAN, A.

RESEARCH INSTITUTE MOVE, VU UNIVERSITY AMSTERDAM

**Bone quality of the Calcaneus in Young Female Gymnasts Training on High versus Low Impact Loading surfaces** Gerrits K.H.L., Crins M.H.P., Van der Eb J. and De Haan A. Research Institute MOVE, Faculty of Human Movement Sciences VU University Amsterdam, the Netherlands **Introduction.** Gymnastics is a demanding sport characterized by high volume loading and high impact loading of both the upper and lower extremities. High impact loading sports are associated with increased risk of injuries and stress fractures. Opposite, high impact loading is associated with higher bone health and higher values of bone quality compared to controls. The purpose of this study was to examine the differences in bone quality between young female gymnasts training on high versus low impact loading surfaces and age-matched control subjects. **Methods.** The local ethical committee approved this study The study included 82 young female

subjects; 18 gymnasts training on high impact surfaces (Hi-group), 26 gymnasts training on low impact surfaces (Li-group) and 38 age-matched control subjects. To determine bone quality, all subjects underwent Quantitative UltraSound (QUS) measurements of the calcaneus with use of the CUBAclinical (McCue CUBAclinicalTM, Contact Ultrasound Bone Analyser). The Broadband Ultrasound Attenuation (BUA), the Speed of Sound (SoS) and the stiffness index (SI) were determined as indices of bone quality. Before examining the effects of different impact loading surfaces on bone quality, the reproducibility of the apparatus was assessed. Results. This study showed that QUS measurements with use of the CUBAclinical are reproducible (ICC .72 - .99), and showed that SoS is influenced by activity shortly before the measurement. Besides, the present study showed that both the Hi-group and the Li-group had higher SoS ( $1685 \pm 32$  m/s and  $1664 \pm 22$  m/s respectively) and SI values ( $105 \pm 19$  and  $93 \pm 17$  respectively), compared to the control group ( $1614 \pm 27$  m/s,  $74 \pm 20$ ,  $P < 0.05$ ), indicating higher bone quality of the calcaneus of gymnasts compared to controls. Moreover, the Hi-group had higher SoS values than the Li-group ( $P < 0.001$ ). To correct for a possible influence of menarche on bone quality, each of the Hi-, Li-, and control group were separated into 2 groups with subjects who did menstruate and those who did not. As a result, differences in bone quality between gymnasts training on high versus low impact loading surfaces disappeared. These results suggest that possibly there is no effect of different degrees of impact loading on QUS parameters of the calcaneus in gymnasts. Conclusion. The present study shows that young female gymnasts have higher bone quality of the calcaneus than controls, suggesting that skeletal loading produces positive adaptive responses in the growing skeleton subjected to repetitive impact loading. Furthermore, the results of this study provide no evidence for a differential effect on these adaptive responses between subjects training on different impact loading surfaces.

### DOES PHYSICAL ACTIVITY INFLUENCE BONE STATUS IN PREPUBERTAL AGE?

BOSNYÁK, E., SZMODIS, M., FARKAS, A., TRÁJER, E., UDVARDY, A., KOMKA, ZS., PROTZNER, A., SZÓTS, G., TÓTH, M.

FACULTY OF PHYSICAL EDUCATION AND SPORT SCIENCES, SEMMELWEIS

Introduction Lifestyle, genetics and environmental factors are established determinants of bone density. The aim of this pilot study was to examine how the influence of football on bone tissue was reflected by the acoustic parameters of bone, measured by calcaneal quantitative ultrasound (QUS) at both heels, whether intensive training causes higher bone density even in childhood and to assess the correlation of stiffness index (SI) with activity level. Methods 78 prepubertal boys, members of a Hungarian football academy and 37 non-athletic controls participated in this pilot study. Calcaneal QUS parameters were examined with a Sonost 3000 bone densitometer. The measurements included speed of sound (SOS, m/s), broadband ultrasound attenuation (BUA, dB/MHz), and a calculated stiffness index (SI, %). Anthropometric data as body weight and height were recorded and body mass index was calculated (BMI, kg/m<sup>2</sup>). Statistical analysis was made by Statistica for Windows 9.0 software, linear correlation, Student t-test were used to compare the groups. Results The mean age of athletes was  $9.97 \pm 1.20$  years, while  $11.03 \pm 1.03$  in the control group. The means of BMI in the two groups were  $16.66 \pm 1.89$  vs.  $19.70 \pm 4.13$ , ( $p < 0.05$ ). Significant correlations were found comparing bone density values to the age in decimal years (SOS right side:  $0.38$ ; BUA right:  $0.28$ ; SI right:  $0.34$ ). Control group had significantly higher SOS values measured on the right heel, than those of the soccer players ( $1499.14 \pm 10.86$  vs.  $1493.31 \pm 10.7$ ,  $p < 0.05$ ). There was no difference between the two groups examining BUA on the right heel ( $75.54 \pm 11.47$  vs.  $71.83 \pm 11.25$ ). The mean SI on the right foot was  $47.58 \pm 9.70$ . Football academy children had significantly lower SI than control children ( $46.25 \pm 9.51$  vs.  $50.37 \pm 9.69$ ,  $p < 0.05$ ). The football players showed higher SOS on the right than on the left side, whereas the BUA differed the opposite way: the rates on the left side were slightly higher than on the right. There was no significant difference between the right and left foot of the soccer players' SI (SI right  $46.26 \pm 9.49$  and SI left  $47.17 \pm 9.93$ ). Discussion The result of the present study shows that no influence of physical activity is observed in prepubertal boys at bone status. Bone density of prepubertal boys is principally determined by the age, and not by the physical activity. Our aim is a longitudinal examination to observe if the high level of physical activity induce any improvement in bone density among the analysed sample. Future data will be required to support our expectations. ### A SURVEY OF BONE HEALTH OF PREMENOPAUSAL RUNNERS IN RECREATIONAL LEVEL FOCUSING ON UCOC, PHYSICAL FUNCTION AND NUTRITION

SUMIDA, S.1, IWAMOTO, J.2, OTANI, T.1,2

KEIO UNIVERSITY

Introduction Exercise and nutrition primarily play an important role in the strategy for reducing the risk of osteoporosis. Exercise has an anabolic effect to bone, and improves the bone strength indices of the femoral neck in children. Regarding nutrition, not only calcium and vitamin D but also vitamin K is known to be important nutritional elements for maintaining bone health. Vitamin K is a cofactor for  $\gamma$ -carboxylation of osteocalcin (OC). Under the vitamin K insufficiency, OC loses an ability to bind the mineral to hydroxyapatite, and then becomes undercarboxylated osteocalcin (ucOC), which is released into blood. Thus, vitamin K status in the bone can be evaluated by measuring the serum ucOC level. It has been reported that Vitamin K supplementation reduces the serum ucOC level, and improves the bone strength indices of the femoral neck in postmenopausal women. Therefore, we hypothesized that both vitamin K supplementation and exercise may contribute to improve bone metabolism and increase bone strength. In this study, a cross-sectional study was conducted to evaluate the relationships among ucOC, physical function and nutritional status of premenopausal runners in recreational level. Methods Forty-two premenopausal women (mean age: 37.9 years) who had habitual running activities at a recreational level (mean quantity: 26.7 km/week) were participated in the study. Serum ucOC was evaluated to assess vitamin K status in the bone. Serum OC and bone-specific alkaline phosphatase (BAP) as bone formation markers, and urinary levels of cross-linked N-terminal telopeptides of type I collagen (NTX) as a bone resorption marker, were also evaluated. Physical function parameters such as muscle strength, muscle power and aerobic capacity were measured and nutritional status was assessed using questionnaires. The relationships among variables were assessed by the Pearson's correlation coefficients focusing on ucOC. Results Significant negative correlations were found between ucOC and age ( $r = -0.415$ ), daily intakes of vitamin D ( $r = -0.425$ ) and vitamin K ( $r = -0.328$ ). Significant positive correlations were found between ucOC and OC ( $r = 0.742$ ) and BAP ( $r = 0.313$ ). However, no significant correlation was found between ucOC and physical function parameters. Discussion It was found that daily intakes of vitamins D and K and bone formation markers, but not physical function parameters, were relevant factors of vitamin K status, evaluated by ucOC, in the bone. These results suggest that age and vitamins D and K intakes may influence ucOC, and that vitamin K insufficiency may be related to an increased bone turnover. Vitamin K nutrition and physical function may independently contribute to bone health in different manners.

## BONE OSTEOGENIC RESPONSES IN SHORT-TERM RESISTANCE TRAINING UNDER HYPOXIA

HONDA, A., KON, M., TAWARA, N., TODO, Y., SUZUKI, Y.

JAPAN INSTITUTE OF SPORTS SCIENCES

**Introduction & Purpose** It is widely known that physical training, such as jump and resistance training, increases BMC and BMD. However, as it takes several months to observe bone quantitative changes by training, there have been few studies that have investigated the effects of short-term training on osteogenic responses. In addition, previous studies reported that acidosis inhibited bone formation. Training under hypoxia induced higher lactate production, i.e. acidosis, compared to under normoxia. Therefore, we hypothesized that training under hypoxia had adverse effects on osteogenic responses. The purpose of this study was to investigate this hypothesis by short-term resistance training under hypoxia. **Methods** Subjects were 16 healthy male, and they were randomly divided into 2 groups; NT (normoxic training, n=7) and HT (hypoxic training, n=9). Subjects performed bench-press and leg-press, 10 time × 5 set for each at 70 % 1RM, 2 times/week for 8 weeks. HT group exercised in hypoxic training room (O<sub>2</sub> = 14.4%), and stayed under the condition for 1 h in each session. At pre and post training, BMD of whole body, neck and total proximal in right femur were measured by DXA. Additionally, at the first and last session, subjects had blood samplings taken at rest under normoxia, baseline, 0, 15, 30 and 60 minutes after training under their condition to analyze serum BAP, OC, ICTP, NTx, and plasma IL-6. All measurements were performed in the morning after overnight fast. Two-way ANOVA was used to examine the main effect and interaction. **Results & Conclusion** The body mass and lean body mass significantly increased in both groups with training. BMD of all sites did not change with training and hypoxia. The rest levels of BAP, OC, and ICTP at the last session were significantly higher than those at the first session, and NTx and IL-6 did not change. Additionally, though all parameters except for NTx at the first session showed significant changes over time, the patterns of changes were similar between the two groups in both training session. There were no significant hypoxia main effects in all parameters, and no significant interactions except for the change of OC at the last session. In conclusion, we demonstrated that short-term resistance exercise increased bone metabolic, especially bone formation though BMD did not change. Additionally, these results indicated that hypoxia did not affect osteogenic responses, contrast to our hypothesis.

## THE EFFECT OF ROWING ON BONE CONTENT REDISTRIBUTION

MOURTAKOS, S.P., KAVOURAS, S.A., BARDIS, K.N., VASILIOU, S., TENTA, R., SIDOSSIS, L.S.

HAROKOPION UNIVERSITY

**THE EFFECT OF ROWING ON BONE CONTENT REDISTRIBUTION** Mourtakos S.P, Kavouras S.A, Bardis K.N, Vasiliou S, Tenta R, Sidossis L.S, Laboratory of Nutrition & Clinical Dietetics, Department of Nutrition and Dietetics, Harokopio University, Athens, Greece **Introduction** The bone response to exercise is site-specific and load-dependent. There is also evidence that elevated levels of bone turnover markers in blood may be found in athletes compared to less active individuals (Maimoun et al., 2004). This research investigated the long term effect of rowing on bone density in elite rowers. **Methods** Forty men assigned into two groups of twenty. The first consisted of world class rowers, while the second of twenty active but no athletic men. Bone mineral density (BMD), body mineral content (BMC) and areal bone mineral density (aBMD) were measured by dual-energy X-ray absorptiometry (DXA). Blood samples were analyzed for bone turnover markers RANKL (Receptor Activator of NF-κB-Ligand) and OPG (Osteoprotegerin). **Results** The results, revealed no statistical difference in total bone density TBMD, total body mineral content TBMC and areal bone mineral density aBMD in most body parts between the elite level rowers and the control group. BMC Trunk (11.5%, p=0.02) and BMC Trunk/ TBMC ratio (6.1%, p=0.01), was statistically higher in rowers than in the control group while BMC legs/ TBMC ratio (3.7%, p=0.007) was statistically higher in the control group. Furthermore the bone turnover markers OPG (20.5%, p=0.03) and RANKL (80%, p=0.01) were statistically higher in rowers than in control group, while OPG/RANKL ratio (32.3%, p=0.01) was statistically higher in the control group. **Discussion** The current indicated that rowing exercise does not induce any significant increase in the TBMD. Nevertheless, rowing may increase BMD at site-specific bone areas (Magkos F., et al 2007). In particular, rowing is associated with an apparent redistribution of bone mass from the lower limbs to the trunk as also seen in other sports like water polo (Kavouras S.A., et al 2006). On the other hand, biochemical markers demonstrated that bone remodeling was more evident in rowers than in the control group. Even though the serum levels of both markers were higher in rowers, RANKL levels were found even higher, indicating substantial rates of bone resorption (Ziegler S., et al 2005, Jurimae J, et al 2006). **References** Jurimae J, Purge P, Jurimae T, von Duvillard SP. ## VISUALIZATION FOR ANATOMICAL AND PHYSIOLOGICAL CHARACTERISTICS OF ACTIVE MOTOR UNITS BY SIMULATION AND INVERSE ANALYSIS OF SURFACE MUAPS

SAITOU, K.I., INOUE, S.2, MIYAZAKI, M.3, ITOH, H.4

1 NAGOYA GAKUIN UNIVERSITY, 2 SAGA UNIVERSITY, 3 OBIRIN UNIVERSITY, 4 NAGOYA INSTITUTE OF TECHNOLOGY

**Introduction** In order to investigate the activity of motor units (MUs) recorded with non-invasive surface EMG method during muscle contraction, we must calculate the surface-EMG-variables such as averaged rectified value, median frequency and muscle fibre conduction velocity (MFCV) from the surface EMGs. These calculation methods supply indirectly the information about the averaged tendency of activities of many MUs, but can not reveal the anatomy and physiology of active MUs recruited during the muscle contraction. In this study, we tried to construct the procedure that could visualize the information about anatomy and physiology of active MUs recruited during muscle contraction. **Methods** The procedure in this study consisted of three parts. First was the part in which the parameters such as location and strength of current source, firing time and MFCV were estimated from measured surface motor unit action potentials (MUAPs) through the inverse analysis. Second was the part which reproduced the surface MUAP train by using the parameters estimated in the first part and the surface MUAP model. The last part was for comparison between measured surface MUAPs and surface MUAPs reproduced in second part. This study used alternative surface MUAPs generated with simulation as measured surface MUAPs which were needed in the first part. The surface MUAP trains were simulated with one to ten models of MUs which were defined about size, depth of centre, current strength, fibre density, muscle fibre conduction velocity and firing rate. **Results and Discussion** In this study, cross correlation coefficients (CC) were used for comparison between alternative surface MUAP trains and reproduced surface MUAP trains. For example, in the case of using one MU model whose size, depth of centre, number of muscle fibres, fibre density and firing rate were 2.0 mm, 6.0 mm, 20 fibres, 6.8 fibre/mm<sup>2</sup> and 20 Hz respectively, CC between the alternative MUAP train and the reproduced MUAP

train was 0.980. The MUAP train was reproduced by MU model whose depth of centre, current strength and MFCV were 5.0 mm, 2.51 nAm and 4.034 m/s, respectively. In the case of using two MUs model, the CC declined to 0.958 with influence of another MU. The possibility of visualization of the anatomical and physiological information for active MUs was shown under the condition of a few MUs recruited. The issues that this system can reveal how many MUs active and the methods how to separate activities of those MUs are still open. References Farina D. et al. (2002). *Biol. Cybern.*, 86, 445-456. ### IS THE USE OF ULTRASOUND-DERIVED PREDICTION EQUATIONS FOR ADULTS USEFUL FOR ESTIMATING TOTAL AND REGIONAL SKELETAL MUSCLE MASS IN JAPANESE PREPUBERTAL CHILDREN?

MIDORIKAWA, T., OHTA, M., HIKIHARA, Y., TORII, S., BEMBEN, M.G., SAKAMOTO, S.

J.F. OBERLIN UNIVERSITY

**Introduction** Skeletal muscle (SM) mass has been used as a very important index for predicting exercise performance and estimating nutritional status during different growth stages. However, there are very few effective field methods to accurately and non-invasively estimate SM mass in children. Recently, we have developed ultrasound-derived prediction equations for estimating total and regional (i.e. arm, trunk, thigh and lower leg) SM mass in adult males and females (Sanada et al. 2006). Ultrasound itself is a non-invasive, safe measure of muscle thickness of the extremities and trunk in children. However, it is unknown whether these adult based equations, which include height and muscle thicknesses, are a valid method to estimate SM mass in children. Thus, the purpose of the present study was to investigate the validity of the adult based equations for total and regional SM mass in Japanese prepubertal children. **Methods** A total of 91 healthy Japanese prepubertal children aged 6-12 years participated in this study (46 boys and 45 girls). Contiguous MRI images with a 1-cm slice thickness were obtained from the first cervical vertebra to the ankle joints as reference data. The SM volume was calculated from the summation of digitized cross-sectional areas. The regional SM volume was determined by anatomical landmarks visible in the scanned images. The volume units were converted into mass by an assumed SM density (1.041g/cm<sup>3</sup>). Muscle thickness was measured by B-mode ultrasound at 9 sites on different muscles (lateral forearm, anterior and posterior upper arm, abdomen, subscapular, anterior and posterior thigh, anterior and posterior lower leg). **Results** When total and regional SM mass were estimated using adult prediction equations, mean values between measured and predicted total and regional segments of SM mass were significantly different for prepubertal children except for the thigh segment for boys. **Conclusion** These results suggest that the adult ultrasound-derived prediction equations are limited availability in prepubertal children. Therefore, a larger study for developing a SM mass prediction model is needed in prepubertal children. **Reference** Sanada K, Kearns CF, Midorikawa T, Abe T. (2006) Prediction and validation of total and regional skeletal muscle mass by ultrasound in Japanese adults. *Eur J Appl Physiol* 96, 24-31.

### STUDY OF BONE AMMOUNT IN FEMALE STUDENTS-A LOOK AT THE RELATIONSHIP AMONG NONE AMOUNT, HIP-JOINT MUSCLE STRENGTH, AND PHYSICAL ACTIVITY-

YAMAMOTO, T.1, KITA, T.2, AKITA, K.3, MIURA, K.3, MIURA, M.3, YOSHIHARA, S.4, TAMURA, M.5, HYUN, C.6, YI, K.7

1:MUSASHINO ART UNIV.(JAPAN), 2:TEIKYO UNIV. OF SCIENCE(JAPAN), 3:TOYO UNIV.(JAPAN), 4:ST.MARIANNA UNIV.(JAPAN), 5:MEJI UNIV.(JAPAN), 6:KAWASAKI UNIV. OF MEDICAL WELFARE(JAPAN), 7:EWHA UNIV.(KOREA)

**Intoroduction:**This study investigated the bone amounts and exercise levels of female students and examined the data based on statistical analysis. It produced some interesting findings concerning the relationship between bone amount and exercise. **Method:**The subjects (female students) were surveyed with respect to the following factors: body measurements, daily activity, bone amount, and hip joint muscle strength. The data obtained were then statistically analyzed. **I Measuring instruments:** (1) Ultrasound bone densitometer, (2) body composition scale, and (3) hip joint muscle strength measuring instrument. **Results:**The subjects were examined as to their physical characteristics,daily activities,bone amount ,and hip-joint muscle strength. The data obtained were used coefficients to carry out various statistical analyses. The analyses. resulted in the following findings:1)The correlation anlysis showed a significantly positive correlation between bone area ratio and the hip-joint abductor strength( $r=.55, p<.01$ ). 2)In the variance analysis, there was a tendency for the abductor strength of subjects who used to play sports in school to be higher on average, among subjects with a very high or very low level of satisfaction with their walking distance and among subjects with particularly high bone amount. However, only the results obtained from subjects with a very low level of satisfaction with their walking distance were statistically significant. 3)In the cluster and cross-sectional analyses, the 39 subjects could be divided into three groups: those with low muscle strength and low bone amount(26 subjects), those with high adductor strength(8 subjects), and those with high abductor strength and high bone amount (5 subjects). No significant variance was seen among the three groups in regard to the proportion of subjects who used to play sports in school. However, four out of the five subjects with high abductor strength and high bone amount used to play sports in school. The ratio is far higher than the comparable ratio for all subjects combined(38.5%). 4)Combining the results of the above three sets of analysis, it was found that there is a close correlation between bone amount,physical activity, and muscle strength. **Discussion/Conclusion:**If exercise is necessary to increase bone amount, and if sufficient bone amount is necessary to improve motor ability and muscle strength, physical education instructors may need to maintain a stronger awareness of the importance of diet, which supports the development of bones and the overall body. In addition to providing better coaching to students on skills and training, it may be necessary to provide guidance on diet while seeking the cooperation of experts in the field. **References:**Yamamoto Tadahiro et al(2008)Research about the masurement of the torque - Comparison of Hip-and Elbow-Joint Muscle Strength Measurements, The12th Annual Congress of the EUROPEAN COLLEGE OF SPORT SCIENCE ,Estoril

### LONGITUDINAL CHANGES IN BONE MASS IN ADOLESCENT CYCLISTS.

**Introduction:** Adolescence is a critical period to improve bone mass and conserve it for lifelong (1). Cross-sectional studies have shown that professional cyclists had low bone mineral density (BMD) (2), which has also seen to decrease during one year of cycling in adults (3). Therefore, the aim of this study was to analyze the changes in bone mass during a one year season of cycling training in adolescence. **Methods:** A total of 16 male adolescents [9 cyclists and 7 controls;  $15.8 \pm 1.4$  years (mean  $\pm$  SD)] participated in this study. The cyclists trained as a mean 14 h/week. Control group continued with their usual activities. Bone mineral content (BMC), BMD and area were determined in the whole body, lumbar spine, hip and hip subregions by dual-energy X-ray absorptiometry (DXA). Two-way repeated-measures ANOVAs were used to evaluate differences in BMD and BMC, adjusted for age and changes in height, lean mass. **Results:** Cyclists were lighter and had less lean and fat masses than the controls at the baseline and after one season period (all  $p \leq 0.05$ ). At initial, cyclists had lower levels of BMC at whole body, pelvis, lower extremities and femoral neck; lower BMD at pelvis, lower extremities and hip; and lower area at whole body and lower extremities (all  $p \leq 0.05$ ). From pre- to off cycling season cyclists increased significantly less the BMC at whole body, pelvis, lower extremities; the BMD at pelvis, lower extremities; and the area at the pelvis (all  $p \leq 0.05$ ). **Discussion:** Adolescent cyclists had lower BMC, BMD and area than normo-active counterparts, also showing decreased bone mass accumulation. Cycling participation during adolescence may negatively affect bone health, involving peak bone mass acquisition. **Acknowledgements:** Funding by Ministerio de Ciencia e Innovación, Instituto de Salud Carlos III (DPS2008-06999) and Presidencia del Gobierno de España, Consejo Superior de Deportes (21/UPB20/10). **REFERENCES** 1. **Weak bone structure in adolescent cyclists.** Guillén-Ballester Aab, Olmedillas Hab, González-Agüero Aab, Gómez-Cabello Aab, Bueno-Fenero Sd, Moreno LAac, Casajús JAab and Vicente-Rodríguez Gab a GENUD "Growth, Exercise, Nutrition and Development" Research Group. Universidad de Zaragoza, Spain. b Faculty of Health and Sport Science (FCSD), Department of Physiotherapy and Nursing. Universidad de Zaragoza, Ronda Misericordia 5, 22001-Huesca, Spain. c School of Health Science (EUCS). Universidad de Zaragoza, C/ Domingo Miral s/n, 50009-Zaragoza, Spain. dHospital Clínico Universitario Lozano Blesa. (Zaragoza) Servicio Cirugía B Aim: Determine the status of bone structure in adolescent male cyclists. **Methods:** nineteen male adolescents (9 cyclists and 10 controls),  $15.8 \pm 1.4$  years old (mean  $\pm$  SD) voluntarily participated in this study. The cyclists group trained at a mean of 7 hours per week for ~3 years. Maximum oxygen uptake, ( $\text{VO}_2\text{max}$ ) was measured in a maximal cicloergometric test. Peripheral quantitative computed tomography (pQCT) was used to analyze the total bone mineral content (TotC), volumetric density (TotD) and area; trabecular and cortical density and area; and cortical thickness and bone/muscle ratio at the diaphysis and epiphysis of tibia and radius. **Results:** cyclists had higher  $\text{VO}_2\text{max}$  than controls ( $59.7 \pm 8.9$  vs.  $48.0 \pm 8.9$  ml/kg/min,  $p < 0.05$ ). Cyclists showed a 25% less TotC, 11.5% lower TotD and 14% lower trabecular density at the diaphysis of the tibiae compared to controls (all  $p < 0.05$ ). Similarly, cyclists exhibited lower cortical area (18%), cortical density (1.8%), and cortical thickness (17.9%); with a bone-muscle ratio 1 point of percentage lower than the control group (all  $p < 0.05$ ). No significant differences were found at the radius except for bone-muscle ratio, which was 0.6 points of percentage lower than in controls ( $p < 0.05$ ). **Conclusion:** these results suggest that cycling during adolescence may be associated with low bone mineral content and density and weaker bone structure compared to adolescents who do not practice cycling. This may negatively affect peak bone mass development and increase the risk of bone fracture later in life. **Funding** This study has been funded by Ministerio de Ciencia e Innovación, Instituto de Salud Carlos III (DPS2008-06999) and Presidencia del Gobierno de España, Consejo Superior de Deportes (21/UPB20/10).

### IMPACT OF PHYSICAL FITNESS ON BONE DENSITY IN A FEMALE GREEK ADOLESCENT POPULATION

SARRA, A.1, SOULTANAKIS, H.2, KARANTZA, M.1, PAPAETHYMIU, M.1, BAKOULA, C.1, CHROUSOS, G.1

1:1ST DEPARTMENT OF PEDIATRICS, ATHENS UNIVERSITY, AGIA SOPHIA CHILDREN'S HOSPITAL, CENTRE FOR HEALTH AND PREVENTION IN ADOLESCENCE; 2: FACULTY OF PHYSICAL EDUCATION & SPORTS SCIENCES, UNIVERSITY OF A

**Introduction** Although peak bone mass is 60% to 85% is genetically determined (Ralston H.S., 2007), environmental and lifestyle factors such as physical activity, have a great impact and they should not be ignored in the prevention and management of osteoporosis, as they are the ones that can be truly modified even since adolescent years. The purpose of this study was to determine the effect of several parameters of physical fitness on total hip bone density in a Greek female adolescent population (Vaughn EJ et al., 2009). **Methods** Sixty healthy female adolescents with a median age of 13.70 (12.00, 15.80) years, recruited at the Centre for Health and Prevention in Adolescence of the 1st Department of Pediatrics, of Athens University, were included. Bone mineral density (BMD) was measured at the upper femur by Dual-Energy X-ray Absorptiometry (DEXA). The European physical fitness test battery (EUROFIT) was used for the assessment of physical fitness parameters (flexibility, explosive and static strength, trunk strength and cardio respiratory endurance). Anthropometric measurements such as: height, weight, Body Mass Index (BMI), and % body fat were also included. Statistical analysis was performed by using the statistical package Stata 10.1. Statistically significant were considered all the results with a two sided  $p < 0.05$ . **Results** Adolescent girls had a mean ( $\pm$  SD) BMD values at the upper femur of  $0.947 \pm 0.144$  g/cm<sup>2</sup>. BMD of the upper femur was positively correlated to weight, height, body mass index (BMI), sum of Skinfold thickness and handgrip strength. Body fat percentage and lean mass were also correlated to higher BMD. There was a negative correlation between  $\text{VO}_2\text{max}$  and BMD. Handgrip strength, BMI and the hours that adolescents devoted to regular exercise were positive and independent predictive factors of bone density. **Discussion** Physical fitness status is an indicator of good health and certain parameters of physical fitness are related to bone health. Such parameter is strength which seems to have predictive value for bone mineral density in female adolescents (Vicente-Rodriguez G. et al., 2008). It is of great importance to specify if these parameters can be used for the early detection of those adolescents with potential risk of osteoporosis later in their life. **References** Ralston HS. ## COMPARABLE EFFECTS OF SLOW RESISTANCE TRAINING AND BRISK WALKING ON BODY COMPOSITION AND BONE HEALTH STATUS IN YOUNG ADULT WOMEN

KIMURA, Y., OHKI, K., NAKAGAWA, N., EZAKI, T., SATO, T.

RESEACH CENTER FOR FITNESS AND HEALTH SCIENCES

**Introduction** Regardless of age or gender, children and adults who maintain an active lifestyle have significantly greater body composition and bone mass than sedentary counterparts. The aim of this study is to assess the effects of resistance training (RT) and walking exercise (WK) on body composition, bone and mental health status in sedentary young adult women. **Methods** Thirty-two subjects (Mean age 20.8 yrs.) were divided into RT group (n=12), WK group (n=13) and control group (CN; n=7). RT group trained four exercises (squat, bent-leg sit-ups, push-up, back extension) using body weight as a load, with slow maneuver four times per week. WK group instructed to wear a pedometer, and walked briskly, more than 10,000 steps a day four times per week. We evaluated body composition, bone status (ultrasound parameters of the calcaneus and urinary deoxypyridinoline (DPD) levels), and mental health parameters, at baseline and after 12 weeks of training session. **Results and Discussion** RT group showed significant changes in fat mass, waist, hip, thigh and upper arm circumferences, and triceps, abdominal and thigh thickness. WK group showed significant changes only in thigh circumference, and abdominal and thigh subcutaneous fat thickness. RT group showed significant changes in ultrasound parameters, such as speed of sound and stiffness. WK group showed small changes in these three items, but the changes were not significant. There was a significant decrease in DPD only in RT group. A significant improvement in RT group was seen in regard to subjective health, everyday feelings, human relations and subjective happiness. The subjective health and subjective happiness increased significantly in WK group. CN group shows no significant changes in any measurements. **Conclusions** It suggest that slow resistance training using body weight as a load was effective to improve body composition and bone health status, and that it is an available method for improving mental health parameters, such as subjective health and life satisfaction, in which resistance training indicated different changes from walking exercise.

#### EFFECT OF ACUTE SPRINT INTERVAL EXERCISE ON POST-EXERCISE OXYGEN UPTAKE, SUBSTRATE METABOLISM AND BLOOD PRESSURE

BURNS, S., CHAN, H.H.M.

NANYANG TECHNOLOGICAL UNIVERSITY

**Introduction** Recent data suggest sprint interval exercise may improve metabolic and vascular risk factors in both normal-weight (Rossow et al., 2010) and overweight (Whyte et al., 2010) individuals with some of the benefit coming from acute rather than training effects. We aimed to examine the effect of acute sprint interval exercise on post-exercise oxygen uptake, substrate metabolism and blood pressure. **Methods** Following ethical approval, eight healthy males (aged  $23.2 \pm 1.2$  y, height  $1.73 \pm 0.07$  m, body mass  $68.5 \pm 9.5$  kg, mean  $\pm$  SD) completed two trials, exercise and control, in a random balanced order. On the exercise trial participants reported to the laboratory at 0830 after a 10-h overnight fast. After 15-min of seated rest each participant performed four 30-s maximal sprints on a cycle ergometer against a resistance equivalent to 6.5% of their body mass. Each sprint was separated by 3-min of active recovery and 1.5-min of passive recovery. Upon completion of the fourth sprint participants were seated in a chair to recover for 2-h. Measurements of oxygen uptake and respiratory exchange ratio (RER) were made continuously for 15-min at baseline and for 2-h post-exercise via a metabolic cart. Blood pressure was measured at baseline and 0, 15, 30, 60, 90 and 120-min post-exercise. On the control trial participants rested in the laboratory with oxygen uptake, RER and blood pressure measured at corresponding times. Baseline measurements were compared between trials using paired t-tests. Two-way ANOVA (repeated measures) was used to determine differences between trials and over time in post-exercise oxygen consumption, RER and blood pressure. Data are mean  $\pm$  SD. **Results** No differences were seen in oxygen uptake, RER or blood pressure at baseline. Oxygen consumption was significantly higher post-exercise than control (exercise:  $45.9 \pm 7.2$  L vs control:  $30.9 \pm 5.5$  L, main effect of trial,  $P < 0.001$ ) with the elevation in oxygen consumption lasting for 30-mins post-exercise (trial  $\times$  time interaction,  $P < 0.001$ ). The RER was significantly raised immediately after exercise but was lower on exercise than control from 30-90-min (trial  $\times$  time interaction,  $P < 0.001$ ). Systolic blood pressure was elevated immediately post-exercise but was significantly decreased on the exercise trial compared with control from 60-120-min post-exercise (trial  $\times$  time interaction,  $P < 0.001$ ). **Discussion** These data demonstrate potential for sprint interval exercise to be considered as an intervention in obesity management and for the prevention of high blood pressure in adults. **References** Rossow L, Yan H, Fahs CA, Ranadive SM, Agiovlaitis S, Wilund KR, Baynard T, Fernhall B (2010). #### SIGNIFICANT RELATIONSHIP BETWEEN SLOW COMPONENT OF OXYGEN UPTAKE KINETICS AND PULMONARY GAS EXCHANGE VARIABLES DURING INCREMENTAL EXERCISE

JEON, Y.1, IM, J.2, KANG, Y.3, KIM, D.4, AHN, M.5, KIM, C.6, KIM, B.7

1-5: KAIST (S.KOREA), 6-7: DAEJEON U. (S.KOREA).

**Introduction** : The objects of this study were (1) to confirm the correlation between the  $\Delta VO_2$  (6th-3rd min) value as a  $VO_2$  slow component and other pulmonary gas exchange variables such as  $VO_{2max}$ ,  $VO_2$  at MRT and  $VO_2$  at AnT, and (2) to obtain the linear regression equation for  $VO_{2max}$  by using  $VO_2$  slow component. **Methods** : Thirty college students performed incremental exercise on treadmill until exhaustion by Bruce protocol. Respired gas fractions at the mouthpiece were continuously measured by mass spectrometry breath-by-breath. **Results** : We verified that the  $\Delta VO_2$  (6th-3rd min) as a  $VO_2$  slow component is closely correlated with  $VO_{2max}$  ( $r = 0.890$ ;  $P < 0.01$ ),  $VO_2$  at MRT ( $r = -0.824$ ;  $P < 0.01$ ),  $\Delta VO_2$  (End of exercise (EE)-6th min) ( $r = -0.821$ ;  $P < 0.01$ ),  $\Delta VO_2$  (EE-3rd min) ( $r = -0.695$ ;  $P < 0.01$ ), and  $VO_2$  at AnT ( $r = -0.688$ ;  $P < 0.01$ ), having inverse proportional relationship. The  $VO_{2max}$  could be estimated with a linear regression analysis;  $[VO_{2max} = -0.049 \times (VO_2 \text{ slow component}) + 68.593, SEE = \pm 2.48, r = -0.890]$ . Other linear regression equations of variables were also gained;  $[VO_2 \text{ at MRT} = -0.041 \times (VO_2 \text{ slow component}) + 52.039, SEE = \pm 2.72, r = -0.824]$ ,  $[\Delta VO_2 \text{ (EE-6th min)} = -3.034 \times (VO_2 \text{ slow component}) + 2769.847, SEE = \pm 205.31, r = -0.821]$ ,  $[\Delta VO_2 \text{ (EE-3rd min)} = -2.034 \times (VO_2 \text{ slow component}) + 2769.847, SEE = \pm 205.31, r = -0.695]$ , and  $[VO_2 \text{ at AnT} = -0.028 \times (VO_2 \text{ slow component}) + 43.222, SEE = \pm 2.87, r = -0.688]$ . **Discussion** : We conclude that the  $VO_2$  slow

component could be the important variable of regression analysis of VO<sub>2</sub>max. The association between VO<sub>2</sub> slow component and VO<sub>2</sub>max can be better predictive of aerobic performance than VO<sub>2</sub>max alone. Also, we can find out the physiological mechanism of VO<sub>2</sub> slow component through exploring the physiological relationship between VO<sub>2</sub> slow component and pulmonary gas exchange variables that have strong correlation with VO<sub>2</sub> slow component.

### ARE STRENGTH AND PULMONARY PARAMETERS RELATED TO SEASONAL PERSONAL BEST IN ELITE YOUTH ROWERS?

ZINNER, C.1,2, KRUEGER, M.1,2, WIRTZ, N.1,2, SPERLICH, B.1,2, KLEINOEDER, H.1,2, MESTER, J.1,2

GERMAN SPORT UNIVERSITY, COLOGNE

**INTRODUCTION:** Ergometer rowing has widely been used in training and preparation of athletes for many years. By the use of spirometric devices with these rowing ergometers a more detailed analysis of performance during their career becomes possible. Further, measuring the development of strength is an essential part of screening the training progress of youth and elite athletes. We hypothesized that the performance on the water of an athlete is correlated with his strength and his pulmonary conditions. To test this hypothesis elite youth rowers of the North Rhine-Westphalia (NRW) squad were tested. **METHODS:** 30 rowers (18 male and 12 female) of the NRW youth squad ( $16.7 \pm 0.9$  yrs;  $184.5 \pm 7.7$  cm;  $78.1 \pm 9.0$  kg) participated in the study. 20 of them took part in international competitions in the last year prior to the study. The athletes performed a ramp test protocol on an indoor rowing ergometer (Concept 2, Model D) to measure VO<sub>2</sub>max (nSpire, Zano 600). The intensity of the first step were oriented to the personal best of the athlete. The first step lasted 2min. After the initial step the resistance was increased by 30 Watt every 30 s until exhaustion. Additionally the maximal isometric and dynamic strength for the m. latissimus dorsi and the m. quadriceps femoris were measured. **RESULTS:** The mean value of rel.VO<sub>2</sub>max was 58.5 ml/kg/min (range 42.2 – 72.2). Rel.VO<sub>2</sub>max as well as the peak power output achieved during the ramp test on the ergometer showed positive significant correlations with the seasonal 500m personal best (pb) (rel.VO<sub>2</sub>max vs. pb:  $p < 0.003$ /  $r = 0.55$ ; PPO vs. pb:  $p < 0.001$ /  $r = 0.92$ ). The isometric and the dynamic strength of the two muscles measured showed significant correlations with the seasonal 500m pb as well (lat.: dyn/iso vs. pb:  $p < 0.001$ /  $r = 0.78$ /  $0.82$ ; quadr.: dyn/iso vs. pb:  $p < 0.001$ /  $r = 0.84$ /  $0.68$ ). **DISCUSSION:** We could show that the correlation between rel.VO<sub>2</sub>max determined on a common rowing ergometer and the performance on the water is on a high level. Vogler et al. (2010) support our results indicating that ergometer rowing simulates rowing on the water on a very high level regarding the used energy systems during maximal and submaximal rowing. The high correlation between the seasonal 500m pb and the results of the isometric and the dynamic strength of the two most important muscles during rowing show that screening these strength conditions could help to increase performance of the athlete and should be taken into account during testing procedures. **REFERENCES** Vogler AJ, Rice AJ, Gore CJ. Physiological responses to ergometer and on-water incremental rowing tests. *Int J Sports Physiol Perform.* 2010 Sep;5(3):342-58.

### THE INFLUENCE OF TRAINING WITH REDUCED BREATHING FREQUENCY ON PERFORMANCE WITH THIS KIND OF BREATHING AND ON CO<sub>2</sub> SENSITIVITY

KAPUS, J., USAJ, A.

UNIVERSITY OF LJUBLJANA, FACULTY OF SPORT

**Introduction** Due to simple regulation of breathing during exercise, reduced breathing frequency (RBF) has been often used during regular swimming training since 1970's. Most of previous studies investigated the acute effects of RBF during exercise. According to our knowledge only one study has examined the influence of training with RBF. Kapus et al. (2005) obtained that swimmers decreased their breathing frequency during a maximal 200 meters front crawl with an optional breathing pattern, due to four weeks of the training with RBF (taking a breath every fourth stroke cycle during front crawl swimming). However, the mechanisms responsible for this training adaptation have been still unclear. Therefore, the purpose of the study was to examine the influence of training with RBF on ventilation during exercise with RBF and on ventilatory sensitivity to inhaled CO<sub>2</sub>. **Methods** Cycle ergometry was used for testing and training. RBF was defined as 10 breaths per minute and was regulated by a breathing metronome. Before and after six weeks of training (three training sessions per week) twelve healthy male subjects (average: age 24, height 180, weight 79, Vo<sub>2</sub>peak 43.3 ml\*kg<sup>-1</sup>\*min<sup>-1</sup>) performed: 1) incremental test with spontaneous breathing (SB) and with RBF to obtain peak power output (PPO) in both breathing conditions (PPOSB and PPORBF), 2) constant test at 50 W with breathing ambient air and hypercapnic gas mixture (3% carbon dioxide, 21% oxygen and 76% nitrogen) to determine CO<sub>2</sub> sensitivity. Subjects were randomly assigned to two groups: experimental (the E group) and control (the C group). At each interval training session subjects in the E group completed from two to eight intervals with RBF of duration equal to 60% and 75% of T<sub>max</sub> (time to exhaustion at PPORBF). The C group performed similar interval set, however, with SB and at PPOSB. Results Both groups increased PPORBF (the E group:  $42 \pm 11$  %, the C group:  $11 \pm 9$  %). However, these improvements were significantly greater in the E group than the C group. Furthermore, the E group had significantly higher peak values of VE ( $39.24 \pm 4.55$  vs.  $28.29 \pm 5.61$  l/min) obtained during incremental test with RBF and lower CO<sub>2</sub> sensitivity ( $18.16 \pm 13.23$  vs.  $31.46 \pm 21.56$  l/min\*kPa) after the training in comparison with pre-training conditions. There were no significant training effects on these parameters at the C group. **Discussion** The results of the present study indicated that the training with RBF increased VE during the exercise with this kind of breathing and decreased sensitivity to higher CO<sub>2</sub>. Both adaptations could be the reasons for greater improvement in PPORBF in the E group in comparison with the C group. **References** Kapus J, Ušaj A, Kapus V, Štrumbelj B. (2005). *KinSi*, 11, 17-24.

### AN INVESTIGATION OF THE ENDOGENOUS COMPONENT OF THE CIRCADIAN VARIABILITY OF MUSCLE FORCE.

ROBERTSON, C., ROBINSON, W., SMITH, M., BURNISTON, J., ATKINSON, G., WATERHOUSE, J., EDWARDS, B.J.

LIVERPOOL JOHN MOORES UNIVERSITY

**Introduction:** Previous findings of time-of-day differences in muscle force output could be confounded by diurnal fluctuations in environmental and behavioural 'masking' factors such as prior sleep, time awake, ambient temperature and energy intake. The purpose of this study was to examine whether there is a circadian rhythm in muscle force that is independent of these masking factors. **Methods:** Ten male trained individuals were assessed for 24-h consecutively in the laboratory. The participants followed a 6-h 'ultra-short' sleep-wake cycle (2-h of sleep in darkness and 4-h of wakefulness in dim light). This protocol distributes behavioural and environmental masking factors equally across the 24-h period and reduces effects due to time awake. After 90-min of each 240-min wake period, participants consumed a standardised meal (~500 Kcal) so that the daily energy intake on test days was controlled (~2500 Kcal). There were four experimental sessions (at 09:00, 15:00, 21:00 and 03:00 h), administered in a counter-balanced design to minimise any learning effects, and there were 72 hours between each trial. Core body temperature was measured rectally, and Perception of Mood State (POMS) questionnaires were completed during each experimental session. The performance measures employed were Biodex isokinetic dyna-

ometry (flexion and extension at 60 and 240° s<sup>-1</sup>) and maximal contractions via isometric percutaneous stimulation of the quadriceps muscles (eight single square-wave electrical impulses, 100  $\mu$ s, over an 8s sampling period, two impulses delivered before and after the contraction with four impulses delivered during contraction). Muscle temperature was taken after the 5 minute warm-up, prior to the isokinetic dynamometry and then prior to the maximal isometric contractions. Data were analysed by cosinor analysis and analysis of variance models. Results: Rectal and muscle temperatures showed significant circadian rhythms ( $P < 0.0005$ ) with acrophases at 16:37 h and 15:31 h, respectively, this is the first time that a circadian rhythm for muscle temperature has been observed. There was a significant time-of-day effect for the POMS variables fatigue and vigour ( $P < 0.05$ ); vigour, which paralleled the rhythm of core temperature, showed an inverse profile to that of fatigue. Discussion: Participants were able to muster physical efforts that were similar to those produced when fatigue was perceived to be less. However, the main finding of this study was that circadian rhythms of the investigated measures of muscle force were weak ( $P > 0.05$ ). Since this protocol minimised fatigue related to time awake, we conclude that conventionally-measured circadian rhythms of muscle force might be considerably influenced by time-awake effects.

### STABILITY OF RATING OF PERCEIVED EXERTION AT LACTATE THRESHOLD

MAMEN, A., BIRKELAND, V., VAN DEN TILLAAR, R.

*SOGN OG FJORDANE UNIVERSITY COLLEGE*

**Introduction** The sensation of physical effort has been tried to be quantified in a number of ways. The scales developed by Gunnar Borg have been widely used for recording perceived physical exertion under different conditions (Noble and Robertson, 1996; Borg and Borg, 2002). The lactate threshold is an entity for intensity description that is used much, and the rating of exertion at this point has been investigated by several researchers (Noble and Robertson, 1996). However, is this rating stable if another protocol was to be used? Therefore the purpose of this study was to investigate how stable the rating would be if the protocol for reaching the threshold point was manipulated. **Methods** 20 trained subjects participated, mean (range) age 40 (24 to 65 yr). Firstly they performed a standard threshold test, warming up at 1.67 m/s for 10 min, then increasing the speed every 5th minute with 0.42 m/s. This test was extended until voluntary exhaustion for recording of maximal oxygen uptake. After the threshold speed had been calculated, the subjects performed two tests in random order; a short protocol that brought them up to their threshold speed in 15 min (3 steps) and a long protocol of 30 min duration (six steps). At each stage rating of perceived exertion (RPE), oxygen uptake and heart rate were recorded. Mean differences were analysed with paired t-tests. Level of significance was set to  $p \leq 0.05$ . **Results** RPE scores differed significantly between the short and the long protocol: mean (95% confidence interval) 13.2 (12.6–13.9) vs. 14.0 (13.3–14.7),  $p < 0.04$ , despite that oxygen uptake: 43.2 ml/kg/min [32.1  $\mu$ mol/kg/s] (41.9–44.5 ml/kg/min) vs. 44.6 ml/kg/min [33.2  $\mu$ mol/kg/s] (43.5–45.7 ml/kg/min), heart rate: 157 beats/min (154–160) vs. 160 beats/min (156–164), lung ventilation: 82.9 L/min (77.5–88.3) vs. 79.7 L/min (73.2–86.2) and breathing frequency: 0.72 Hz (0.67–0.77) vs. 0.72 Hz (0.67–0.77) being equal in the two protocols. Significant correlations ( $p < 0.05$ ) were found between percentage of maximal RPE and both the percentage of maximal pulmonary ventilation ( $r = 0.91$ ) and percentage of maximal breathing frequency ( $r = 0.80$ ). **Discussion** The findings indicate an effect of duration on the subjective sensation of effort also in step protocols. The longer protocol allowed for more heat to accumulate, and the time spent near the threshold velocity was longer due to the smaller increases in velocity of that protocol. Such factors may be important for the sense of effort. Lung ventilation and breathing frequency was strongly correlated with RPE, and with a longer time with elevated respiration, the perceived effort increased. This is important knowledge when designing training programmes based on RPE scores, as even small differences in RPE might give critical differences in intensity. **References** Borg, E, Borg, G. *Acta Psychol (Amstl)*. **Introduction** The ability to accurately control and monitor exercise intensity (EI) during training sessions plays a key role in planning the athletic season. This can be achieved by means of rating of perceived exertion (RPE) (Borg, 1998) and heart rate (HR) (Achten and Jeukendrup, 2003). Over the years several RPE- and HR-based methods have been proposed to quantify global EI. However, to date no study has been conducted with regards to race walking (RW). Thus, this case study aimed to investigate the typical RPE and HR seasonal variations of an international level race walker training for a 50-km race and to examine the relationship between RPE and HR to further confirm the use of RPE to assess EI during RW-specific training. **Methods** Training data were collected during the competitive season 2009 (127 training sessions) consisting of four macrocycles of intense training interspersed by one week of tapering before the Italian 50-km championship. The Borg's 6-20 RPE scale (Borg, 1998) was used to measure the athlete perception of effort referred to the whole training session. HR was recorded using a short-range telemetry system and expressed relative to the maximum value (%HRmax) of the athlete determined during an incremental maximal test. The relationships between RPE and %HRmax were analysed using Pearson's product moment correlation. Statistical significance was set at  $P < 0.05$ . **Results** The athlete completed the event in 4h 14min 02s (personal best time, 39min 48s slower than the World Record). The mean RPE was 11.1 (1.6), 13.1 (1.3), 13.2 (1.5), 12.4 (1.3) and 11.4 (1.0), 13.5 (0.8), 12.7 (0.4), 12.0 (1.5) for the training and tapering period, respectively. The mean %HRmax was 83.7 (2.0), 85.3 (4.6), 84.8 (4.1), 85.7 (3.8) and 83.0 (0.7), 85.7 (4.5), 84.8 (1.6), 85.4 (2.5) % for the training and tapering period, respectively. The correlation between the mean RPE and %HRmax showed a very large significant relationship ( $r = 0.74$ ,  $P = 0.04$ ). **Discussion** The result found indicates that a very large and significant relation exists between RPE and HR. This finding is in line with previous studies which showed how RPE is correlated with many physiological variables, such as HR (Chen et al., 2002), and provides evidence which confirms that RPE can be considered a simple and valid method for quantifying the global EI during RW-specific training. **References** Achten J, Jeukendrup AE. **Introduction** Recent studies have opened a debate about the neurophysiological bases of the perceived effort (PE) (Marcora, 2009). The fluctuations dynamics of the parameter during exercise might give a hint on the type of interaction existing between the different inputs

which form it. Our aim was to study the fluctuations dynamics of the PE during a continuous cycle ergometer test performed until the exhaustion point. Methods Nine physically-active students, who were previously familiarized with the experiment protocol, performed a continuous cycle ergometer test at a previously determined intensity (rate of 4 on the modified Borg scale) until they were unable to maintain the established pedalling frequency for more than 30 s. During the test they reported every change in their PE (any increase or decrease) at least every 15 s. The obtained data series of these changes were integrated and divided into ten non-overlapping temporal windows. The median probabilities of finding either an increase or a decrease in PE were calculated for these windows and for each participant, and were then compared using the Friedman ANOVA test. The Kendall's coefficient of concordance was also calculated with aim to test the behavioural consistency of probabilistic measures among temporal windows. Results The instability of PE dynamics was observed throughout the trial and was manifested in two different time scales (tenths of minutes and minutes). The analysed data series revealed significant differences between the probabilities of fluctuations ( $p < 0.01$ ), as well as low consistency ( $r = 0.39$ ) among the ten windows. Three main portions were distinguished, coinciding with the initial, middle and end part of the test. The median probability of finding an increase in PE was high in the first period (85%), reached a plateau in the middle periods (60%), and then rose progressively to 100% in the last two periods. Discussion The greater probability of finding increases in the PE in the first and, especially, the last portion may correspond, respectively, to the uneasiness that accompanies the change of exercise intensity (also known as second breath) and to the closeness of the termination point. The observed dynamics in the different time scales point towards complex links between the psychological and neuromuscular activation during fatiguing exercise (Hristovski & Balagué, 2010). In conclusion, PE seems to show fluctuating dynamics in different time scales during continuous cycle ergometer exercise performed until the exhaustion point. ### CHANGES IN RESPIRATORY FUNCTIONS DURING SNOW SHOVELING WITH PAST MEDICAL HISTORIES OF BRONCHIAL ASTHMA

TAKAGI, Y.1, WAKURI, H.2, NISHIMURA, K.3, FUJIWARA, Y.4, ARAKANE, K.1, HAYASHI, S.4, ONODERA, S.5

1: GRADUATE SCHOOL, KAWASAKI UNIVERSITY OF MEDICAL WELFARE, 2: IINAN TOWN, 3: HIROSHIMA INSTITUTE OF TECHNOLOGY, 4: GRADUATE SCHOOL, HIROSHIMA UNIVERSITY, 5: KAWASAKI UNIVERSITY OF MEDICAL WELFARE

Introduction: The purpose of this study was to investigate changes in respiratory functions during snow shoveling with past medical histories of bronchial asthma. Methods: 7 Japanese males (age:  $23.3 \pm 2.4$  years, weight:  $67.3 \pm 9.7$  kg, height:  $174.1 \pm 7.8$  cm) with a past medical history of bronchial asthma (=Asthma group) and 6 controls (=Non-asthma group, age:  $24.3 \pm 3.7$  years, weight:  $75.2 \pm 16.3$  kg, height:  $171.5 \pm 6.6$  cm) volunteered to remove snow (15 minutes) in December 2010. Changes of participant's FEV%, FEV1.0, and SpO2 were measured at rest time (room) and after a lapse of 5 minutes from end of snow shoveling (Ex 5). Ambient temperature was set 21.0 degrees C, and atmospheric temperature was  $1.5 \pm 1.1$  degrees C. Results: There were no significant changes in measured value at rest between groups. Significant reductions in FEV% ( $78 \pm 7\%$ ), FEV1.0 ( $3.75 \pm 1.09$  L) and SpO2 ( $95 \pm 2\%$ ) were observed at Ex5 in Asthma group ( $p < 0.05$ ). No significant differences were found on them (FEV%:  $88 \pm 7\%$ , FEV1.0:  $4.51 \pm 0.76$  L, SpO2:  $96 \pm 1\%$ ) in Non-asthma group. Asthma group demonstrated lower each measurement at Ex5 as compared with the values of Non-asthma group. Discussion: Based on the results, stress on respiratory functions was indicated greater after snow shoveling in Asthma group. It was considered that caused significant decrease in FEV%, FEV1.0 and SpO2 were enhanced airway reactivity by synergistic effects of increase of oral-breathing from high-intensity intermittent work and exposure to cold temperature. Though conditions in Asthma group after snow shoveling indicates mild asthma attack in clinical estimation, it was safety range of work. Conclusion: These data suggest that stress on respiratory functions was indicated greater when removing snow for 15 minutes in cold environment in individuals with past medical histories of bronchial asthma. ### PP-PM17 Physiology: Circadian/Precooling

#### THE EFFECT OF SUPPLEMENTAL OXYGEN, WATER IMMERSION OR MASSAGE THERAPY ON POST-EXERCISE INFLAMMATION, PERCEPTUAL RECOVERY, AND NEXT DAY PERFORMANCE.

PEELING, P.1,2, FULTON, S.1, SIM, M.2, WHITE, J.2

1: THE WESTERN AUSTRALIAN INSTITUTE OF SPORT, 2: THE UNIVERSITY OF WESTERN AUSTRALIA

Introduction The effect of different recovery modalities on post-exercise inflammatory responses, perceptual recovery, and subsequent day performance was investigated. Methods Eight trained athletes completed four swimming sessions consisting of 20 x 200 m efforts, in a repeated-measures, counterbalanced design. At the conclusion of each session, athletes undertook a 30 min recovery modality, including either; contrast water therapy (CWT), massage therapy (MT), supplemental oxygen (HYP), or passive rest (CON). Venous blood samples were collected pre- and post-swim, and immediately after the 30 min recovery intervention, which were analysed for levels of Interleukin-6 (IL-6). Additionally, athletes were asked to rate their perceived recovery at the conclusion of the 30 min intervention, and upon returning to the pool 12 h later, after which, a 200 m time-trial was completed as a measure of next day performance. Results The results showed that there was a significant increase in IL-6 at the completion of exercise, which persisted after 30 min of recovery ( $p < 0.05$ ); however, there were no differences between groups. The athletes perception of recovery recorded immediately after the 30 min recovery period was significantly lower in the CON trial when compared to the other three modalities ( $p < 0.05$ ); however, there were no differences in the 12 h post-recovery 200 m time-trial performances. Discussion These results suggest that a 30 min recovery intervention using CWT, MT or HYP has limited influence on reducing the inflammatory response or on improving subsequent day performance. However, athletes may acutely perceive their recovery to be greater when some form of intervention is implemented.

**PRECOOLING LEG MUSCLE PRIOR TO AND DURING WARM-UP FOR INTERMITTENT SPRINT EXERCISE IN THE HEAT.**

SNELLING, A., CASTLE, P., MAXWELL, N.

UNIVERSITY OF BRIGHTON

**Introduction** Twenty minutes of thigh muscle precooling has shown to improve intermittent sprint performance in the heat by ~4% (Castle et al. 2006). Central fatigue mechanisms have been proposed for reduced performance in prolonged activities in the heat in comparison to a temperate environment (Kay et al. 2001). Precooling may influence central activation of exercising muscles, leading to improved self-paced endurance exercise (Duffield et al. 2010). The influence of a warm-up following precooling, including cooling during this period has however, received little attention. This study investigated the effect of precooling and warm-up cooling of the thigh on central activation of the rectus femoris muscle during intermittent sprint exercise in the heat. **Methods** Seven males performed four cycling intermittent sprint protocols (CISP) in hot, humid (30°C, 50% relative humidity) conditions following 20 minutes localised thigh precooling (PRE), 7 minutes warm-up cooling (W-UP), precooling and warm-up cooling (COMB) or no cooling (CON) in a randomised order. The CISP consisted of twenty, 2 minute periods (10s passive rest, 5s maximal sprint, 105s active recovery). Maximum voluntary contraction of the rectus femoris muscle was performed to normalise sprint EMG data. Muscle temperature of the vastus lateralis (Tm) was also measured. Results Average peak power output (PPO) showed an 8% increase in PRE (982±166W) over CON (911±161W P<0.05). No such increase was evident for COMB or W-UP (928±161W, 930±160W respectively P>0.05). Resting Tm (33.5±2.4°C) was reduced by precooling in PRE and COMB to 19.3±2.1°C and 20.2±2.9°C respectively (P<0.05). Prior to the CISP, Tm was 35.1±1.8°C, 33.3±2.9°C, 31.3±2.7°C\* and 29.9±1.6°C\* for CON, PRE, W-UP and COMB respectively (\*P<0.05 in comparison to control). There was no difference in post CISP Tm across all conditions (P>0.05). Localised thigh cooling did not influence central activation of the rectus femoris during the CISP for any condition. **Discussion** Twenty minutes of precooling the leg muscles improved intermittent sprint performance in the heat (PRE) by 8%, supporting findings of Castle et al. (2006), and occurred without a concomitant increase in EMG activity. Continuing cooling in the warm-up (COMB) did not further enhance intermittent sprint exercise in the heat but did blunt the rise in Tm seen in PRE. Precooling followed by a warm-up (PRE) improves the Temperature-Force relationship of muscle and enhances intermittent sprint exercise in the heat. **References** Castle P, MacDonald A, Philp A, Webborn A, Watt P, Maxwell, N. 2006. *J Appl Physiol*, 100, 1377-84. **COMPARISON OF DIFFERENT PRECOOLING TECHNIQUES AND THEIR EFFECT ON REPEAT SPRINT ABILITY IN NON HEAT ACCLIMATISED TEAM SPORT ATHLETES**

BRADE, C., DAWSON, B., WALLMAN, K.

UNIVERSITY OF WESTERN AUSTRALIA

**Introduction** The effect of precooling on repeat sprint performance has had limited research attention. Wearing an ice jacket and the ingestion of an ice slushy prior to performance represent convenient methods of precooling and have been separately shown to enhance exercise performance (Arngrimsson et al., 2004; Siegel et al., 2010; Uckert and Jock, 2007; Ishan et al., 2010). Using multiple cooling methods simultaneously as a precooling strategy has yet to be researched. Therefore, the aim of this study was to compare different precooling methods, both individually and in combination, on repeat sprint performance. **Methods** Twelve male team sport players were randomly assigned (counterbalanced) to four experimental conditions, including a cooling jacket with phase change material (PC25), ingestion of an ice slushy (IS), the combination of the cooling jacket and ice slushy (PC25 + IS), and a control condition (CONT). Experimental sessions consisted of a 30 min precooling period followed by a 70 min repeat sprint cycling protocol that consisted of 2 x 30 min periods of exercise and a 10 min (half time) cooling period. Each half comprised 30 x 4 s maximal sprints interspersed with exercise at varying intensities. Exercise was completed in hot and humid conditions (~35.0°C and 60% RH). Physiological measures included core (TC) and skin temperature (TSk), heart rate, nude body mass, rating of perceived exertion and thermal sensation. Performance measures obtained were peak and mean power and work done. Results Total mean power and work performed were significantly higher in the PC25 + IS compared to IS condition. Effect sizes indicated a trend for lower TC in PC25 + IS compared to PC25 and CONT conditions (precooling) and compared to the IS condition (half time). The change in mean TSk over half time was significantly greater during the PC25 condition compared to IS, and showed a tendency for a greater change compared to all other conditions. Total sweat loss was significantly greater in the IS and PC25 + IS conditions compared to the PC25 and CONT conditions. **Discussion** This study shows that intermittent sprint performance in hot and humid conditions, was enhanced by using two methods of precooling simultaneously, perhaps facilitated by a trend for a lower TC in the PC25 + IS condition. The use of an ice jacket containing phase change material and the ingestion of an ice slushy provide convenient methods of precooling which are easily applied within the time constraints of team sports in field settings. **References** Arngrimsson S, Petitt D, Stueck M, Jorgensen D, Cureton K. **COLD WATER IMMERSION DOES NOT INFLUENCE MUSCLE GLYCOGEN RE-SYNTHESIS FOLLOWING EXHAUSTIVE EXERCISE**

GREGSON, W.1, ALLAN, R.1, HOLDEN, S.1, PHIBBS, P.1, CAMPBELL, I.1,2, WALDRON, S.1,3, JOO, C.1, MORTON, J.1

LIVERPOOL JOHN MOORES UNIVERSITY, UK, 2 UNIVERSITY HOSPITAL OF SOUTH MANCHESTER, UK 3 LANCASHIRE TE

Cold water immersion does not influence muscle glycogen re-synthesis following exhaustive exercise Warren Gregson<sup>1</sup>, Robert Allan<sup>1</sup>, Susan Holden<sup>1</sup>, Padraic Phibbs<sup>1</sup>, Iain Campbell<sup>1,2</sup>, Sarah Waldron<sup>1,3</sup>, Chang Hwa Joo<sup>1</sup>, James Morton<sup>1</sup> <sup>1</sup> Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, UK <sup>2</sup> Department of Anaesthesia, University Hospital of South Manchester NHS Foundation Trust, UK <sup>3</sup> Lancashire Teaching Hospitals NHS Trust, UK. **Introduction** Cold water immersion (CWI) enhances post-exercise recovery (Bailey et al., 2007). Potential mechanisms include cold induced reductions in limb blood flow (Gregson et al., in press) which may reduce muscle damage and inflammation following exercise. However, this reduction in limb blood flow may also be problematic as it could result in reduced substrate delivery thereby reducing the efficacy of post-exercise nutritional interventions. The aim of the present study was to therefore test the hypothesis that post-exercise CWI reduces muscle glycogen re-synthesis following exhaustive exercise. **Methods** Nine healthy males (24±4 years) performed exhaustive cycling (on the morning after having completed intermittent exhaustive cycling the evening before) on two separate occasions in a counterbalanced randomised crossover design. On each occasion, subjects rested passively (CON) or undertook 10-min of CWI (8oC) 20-min after the completion of exercise. Carbohydrates were consumed at hourly intervals (0.6 g/kg body mass) during the 4h recovery period. Muscle biopsies, rectal, muscle and skin temperature

were taken at regular intervals during the 4h recovery period. All data were analysed using a two-factor (condition x time) within participants general linear model (GLM). Results Rectal temperature was similar between conditions during the 4 h recovery period ( $p = 0.30$ ), however, skin and muscle temperature were significantly lower in the CWI condition compared to CON ( $p < 0.001$ ). Muscle glycogen levels were similar at exhaustion ( $\sim 75$  mmol/kg dw;  $p = 0.72$ ) and increased by similar amounts after 1 h (CWI,  $99 \pm 29$ ; CON,  $91 \pm 34$  mmol/kg dw) and 4h (CWI,  $157 \pm 59$ ; CON,  $160 \pm 34$  mmol/kg dw) of recovery ( $p < 0.01$ ). Discussion Data demonstrate that reduced limb blood flow in response to CWI (Gregson et al., in press) does not influence rates of muscle glycogen re-synthesis following exhaustive exercise. Cold water immersion is therefore unlikely to have adverse effects on athletes where short recovery periods between successive bouts of training and competition necessitates the rapid replenishment of muscle glycogen stores. ## DOES RAISING MORNING RECTAL TEMPERATURE TO EVENING LEVELS OFFSET THE DIURNAL VARIATION IN MUSCLE FORCE PRODUCTION?

EDWARDS, B.J., PULLINGER, S.A., KERRY, J., ROBINSON, W., ROBERTSON, C., WATERHOUSE, J.M.

LIVERPOOL JOHN MOORES UNIVERSITY

**Introduction** Muscle force production and power output in active males, regardless of the site of measurement (hand, leg or back), is higher in the evening than the morning. This diurnal variation is attributed to motivational, peripheral and central factors and higher core temperatures in the evening. Therefore, the purpose of this study was to investigate whether increasing morning rectal temperatures to evening resting values, by active or passive warm-up, leads to muscle force production and power output becoming equal to evening values in motivated subjects. **Methods** Ten healthy active males (mean  $\pm$  SD: age,  $21.2 \pm 1.9$  years; mass,  $75.39 \pm 8.32$  kg; height,  $175.6 \pm 6.0$  cm) completed the study. The subjects were familiarized with the techniques and protocol and then completed four sessions (separated by  $>48$  h): control morning (07:30h) and evening (17:30h) sessions and then two further sessions at 07:30h but preceded by active or passive warm-ups to raise core temperature to evening values. The sessions were counterbalanced in order of administration. During each trial, 3 measures of handgrip, isokinetic leg strength measurements (of knee flexion and extension at  $1.05 \text{ rad.s}^{-1}$  and  $4.19 \text{ rad.s}^{-1}$  through a  $90^\circ$  range of motion) and 4 maximal voluntary contractions (MVC) on an isometric ergometer (utilizing the twitch-interpolation technique) were performed. Rectal temperature, rating of perceived exertion (RPE) and thermal comfort (TC) were measured. Measurements were made after the subjects had reclined for 30min at the start of the protocol and after the warm-ups and prior to the measures for strength. Warm-ups were either active (cycle ergometer at 150W) or passive (resting in a room at  $35^\circ\text{C}$ ). Data were analysed using ANOVA models with repeated measures. Results Rectal temperatures were higher at rest in the evening ( $\sim 0.53^\circ\text{C}$ ;  $p < 0.05$ ) but there were no differences after the active or passive warm-ups, the subjects' ratings of TC reflecting this. Right grip strength, isokinetic knee flexion for peak torque and peak power at  $1.05 \text{ rad.s}^{-1}$  and knee extension for peak torque at  $4.19 \text{ rad.s}^{-1}$ , all showed higher values in the evening. All other measures of strength and power showed a statistical trend to be higher in the evening than in the morning ( $0.10 > p > 0.05$ ). There was no significant effect of 'warm-ups' on any strength and power variables, and subjects reported maximal values for effort and RPE for each strength measure. In summary, effects of time of day were seen in some measures of muscle performance, in agreement with past research. However, in this population of motivated subjects, there was no evidence that increasing morning rectal temperature to evening values by active or passive warm-up increased muscle strength to values found in the evening.

## EFFECTS OF MORNING OR EVENING WHEEL-RUNNING ON THE PHASE OF CIRCADIAN RHYTHM AND THE EXPRESSION OF CLOCK-CONTROLLED METABOLIC-RELATED GENES IN MICE

ANDO, K.1,2, MORIYA, Y.2, HIRAO, A.2, UCHIDA, S.1, SHIBATA, S.2

WASEDA UNIVERSITY

**Introduction** It is known about the good effects of exercise on our health and energy expenditure, however we do not know the best clock time of day for exercise. Mammals including human have circadian clock systems which are operated by clock genes expressed in the brain, peripheral organs and skeletal muscles. Therefore, it is interesting to know (1) that time-dependent exercise can reset circadian rhythm similar to light-induced reset, and (2) that time-dependent exercise can cause anti-obesity effect. So, we studied whether morning exercise or evening exercise can reset mice peripheral clock and can reduce weight gain through the expression of clock-controlled metabolic-related genes in liver, adipose and muscles under high fat diet feeding conditions. **Materials & Methods** We accomplished 2 experiments. Firstly, we examined the effects of voluntary wheel-running with fixed-time (ZT0-4, or ZT12-16) on the phase of liver bioluminescence rhythm in the mouse carrying with Per2::luciferase knock-in. ZT0 is lights-on time and ZT12 is lights-off. Secondly, we examined the effects of voluntary wheel-running on the expression of clock-controlled metabolic-related genes in the liver and soleus muscle. Mice were applied to exercise for 4 weeks with wheel running during early night (ZT23.5-0) or early morning (ZT12-12.5). Mice were kept under LD condition (L:D=12h:12h) and allowed free access to drinking water and High Fat Diet (25% fat). **Results** (1) No phase-shifting effect was observed by fixed-timed wheel-running, suggesting that physical activity itself does not influence the liver and soleus clocks. It means that the entraining effect of the exercise on Per2, Bmal-1 rhythm is weaker than that of light simulation. (2) The numbers of wheel-running was comparable between morning exercise group and evening exercise groups suggesting the same exercise load between two groups. Whereas, body weight gain and size of visceral and subcutaneous fat was lower in evening group than morning group. The expression levels of Ppar $\alpha$ , mUCP3, Rev-erba were higher in evening group than in morning group. Thus, evening exercise more strongly promoted the expression of metabolic-related genes. **Discussion** We found that evening exercise promotes energy expenditure more than morning one in mice, and that evening exercise increases the expression of metabolic-related genes. These results suggest that people can make more metabolic activation with evening physical exercise without phase-shift of peripheral clock. Exercise program considering clock time of exercise may be useful for the prevention and improvement of obesity in human. References C.Canto et al.(2009) *Nature*, Apr 23;458(7241):1056-60. ### TEMPERATURE CIRCADIAN VARIATIONS IN WORKER IN HOT ENVIRONMENT

RACINAIS, S., FAROOQ, M.A., FERNANDEZ, J., HYNES, R., GRANTHAM, J.

ASPETAR, QATAR ORTHOPAEDIC AND SPORTS MEDICINE HOSPITAL - QATAR ALUMINIUM LIMITED

**Introduction:** Body core temperature follows a circadian rhythm. This rhythm is endogenous with an acrophase around 18h00 in temperate environment. This rhythm persists at rest in hot countries but the acrophase can be advanced according sunrise and sunset time. However, the effect of working in hot conditions on this rhythm is not known. **Research questions:** Does core temperature follow circadian variations under working conditions in hot environment? What are the characteristics of these variations? Does this affect the health and safety of worker having shift work? **Methods:** 29 employees from the aluminum industry participated in this preliminary study. These participants worked indoors where the temperature was typically in excess of 40°C; however, there were isolated areas above 70°C. Additionally, each worker wore protective clothing consisting of suit, gloves and mask. Core temperature (ingestible pill) data covering a 24-h circadian cycle were obtained in 10 workers during morning, afternoon and night shifts over three separate days. Circadian variation in temperature was characterized using a cosinus function (cosinor model). The mesor (average) and acrophase (time of the peak) of the function have been calculated for each participant as well as for the entire population. **Results:** Body core temperature at work fluctuates during the day with an acrophase at 15h50 and a mesor of 37.45°C. This represent an average core temperature half a degree higher than generally observed in general population at rest. There are large differences between the individual acrophase times probably due to different working activities as well as the influence of synchronization/shift from the previous days. However, core temperature was consistently higher in the afternoon than during the morning or the night. Peak values of core temperature showed an acrophase at 14h57. **Discussion:** The current data showed that workers from the aluminum industry present relatively elevated average core temperature with the highest values being reached during the afternoon shift. This suggests that special attention should be given to the afternoon shift and that break/cooling procedure should be implemented if necessary. These preliminary observations have to be completed by clinical and behavioral observations.

### DOES RAISING MORNING RECTAL TEMPERATURE TO EVENING LEVELS OFFSET THE DIURNAL VARIATION IN MUSCLE FORCE PRODUCTION?

PULLINGER, S.A., ROBINSON, W., ROBERTSON, C., WATERHOUSE, J.M., EDWARDS, B.J.

RESEARCH INSTITUTE FOR SPORTS AND EXERCISE SCIENCES,

**Introduction** A plethora of research has shown distinct cyclic variation to be present in core temperature throughout the solar day (Drust et al., 2005: Chronobiol Int. 22:21–40). It is well documented that muscle strength and power output, regardless of the site (grip, leg, back etc.), are higher in the evening than the morning and thus display circadian rhythmicity in phase with the rhythm of core temperature (Reilly and Waterhouse, 2009: Eur J Appl Physiol. 106:321-332). The purposes of the present study were to investigate whether muscle contraction (using a muscle lab force-velocity transducer) displays diurnal variation and whether increasing morning rectal temperatures to evening values by an active warm-up leads to an increase in muscle contraction in the morning to evening values in motivated subjects. **Methods** After having been familiarized with the techniques and protocol, ten healthy active males (mean  $\pm$  SD: age 21  $\pm$  1.3 yrs, height 176.5  $\pm$  5.9 cm and body mass 82.8  $\pm$  15.7 kg) completed three sessions (separated by at least 48 h); a morning (07:30 h) session, an evening (17:30 h) session, and a further morning (07:30 h) extended active warm-up session, where rectal temperatures were increased to evening levels. During each trial, 3 measures of handgrip strength, bench press and back squat were performed. Rectal (T<sub>rec</sub>) and intra-aural temperatures, thermal comfort and effort were measured throughout. Three measures of muscle temperature were also taken. The local Ethics Committee of the University approved the study. **Results** Values of T<sub>rec</sub> (~0.63°C) and intra-aural (~0.50°C) values were higher at rest in the evening compared to the morning (P<0.05) and there was no difference from the evening resting values after the active warm-up in the morning (P>0.05); these differences were reflected by the subjects' ratings of thermal comfort. Muscle temperatures also displayed significant diurnal variation, with higher values in the evening (P<0.05). Left and right isometric grip strength, average power and force and peak velocity at 20 kg load for bench press, and average power and peak velocity at a 40 kg load for bench press, all showed diurnal variations with evening values greater than in the morning (P<0.05). All other measures of strength and power showed no diurnal variation. There was no effect of active warm-up on any strength or power variable, these still remaining below evening values, and subjects reported maximal values for effort and RPE for each strength measure. **Discussion** These results suggest that the muscle lab force-velocity transducer used in this study might not be sensitive enough to detect diurnal variation in all strength measures. In addition, in this population of motivated subjects, there was no evidence that increasing morning rectal temperature by an active warm-up to evening values increased muscle strength to that found in the evening. This result agrees with Reilly and Waterhouse (2009), who suggested that the rhythm of muscle strength might not be wholly mediated by core temperature variation.

### RELATIONSHIP BETWEEN DAILY PHYSICAL ACTIVITY LEVELS AND BEDTIME MELATONIN CONCENTRATIONS IN SCHOOL-AGE CHILDREN

SHIMAMOTO, H.1, SHIBATA, S.2, WAKAMURA, T.3, SHIBATA, M.4

1: OSAKA UNIVERSITY (OSAKA, JAPAN), 2: KOBE CITY COLLEGE OF NURSING (KOBE, JAPAN), 3: KYOTO UNIVERSITY (KYOTO, JAPAN), 4: UNIVERSITY OF HYOGO (AKASHI, JAPAN)

**Introduction** In recent times, the bedtimes of school-age children in Japan have gradually extended, and their total sleep time has decreased. From the viewpoint of growth and development, it is very important that school-age children have sufficient sleep at suitable hours. Exercise has been considered a synchroniser of human circadian rhythms (Miyazaki et al. 2001, Shibata et al. 2010), and an inactive lifestyle may cause retreatment of circadian rhythms. The purpose of this study was to determine the effect of daily physical activity (DPA) levels on the circadian rhythm of melatonin in school-age children. **Method** The study population comprised 55 boys (age, 9–11 years). We determined their DPA levels, melatonin levels at bedtime, waking times, and bedtimes over a 1-week period. DPA was defined as the number of steps taken daily and was determined using accelerometry. Saliva samples were collected at bedtime on 2 week-nights, and the saliva melatonin concentrations were determined. We thought that bedtime melatonin concentrations would be affected by the childrens' social schedules, e.g. the waking time and the bedtime; therefore, we analyzed the subjects whose waking times and bedtimes were within the range of 1 standard deviation (SD) of the mean waking time and bedtime of all the subjects. **Results** The grand means of the waking times and bedtimes were 6:36 (SD, 26 min) and 22:06 (SD, 35 min), respectively; therefore, we analyzed the data for the 24 subjects who woke up between 6:10 and 7:02 and went to bed between 21:31 and 22:41. The mean (SD) values for DPA levels and bedtime melatonin concentrations were 17,163 (3,330) steps and 8.6 (5.3) pg/ml, respectively. A significant positive correlation ( $r = 0.63$ ,  $p$

< 0.01, n = 24) was observed between the DPA levels and bedtime melatonin concentrations. Discussion In this study, the subjects had similar social schedules; however, the bedtime melatonin concentrations were correlated with DPA levels. Our results suggest that lower DPA levels cause retreatment of the circadian rhythms of melatonin and that increased DPA levels contribute to synchronization of circadian rhythms in children. ### **SLEEP AND REST-ACTIVITY CIRCADIAN RHYTHM AFTER CONTINUOUS SPORT COMPETITIONS LASTING THREE TO SEVEN DAYS. COMPARISON BETWEEN THREE DIFFERENT RACES.**

CALOGIURI, G., WEYDAHL, A.

*FINNMARK UNIVERSITY COLLEGE*

**Introduction.** Rest-activity circadian rhythm is strongly linked to the organism's entrainment. Sleep loss and prolonged fatigue might affect the circadian system, inducing neuro-behavioral deficits. Finnmarksløpet (FL) is Europe's longest sled-dog race, with a 500km and a 1000km category. The competition lasts up to 7-days; the participants (mushers) are physically active most of the time, having little and fragmented rests. The same is the situation in the about 5-days 700km biking event OffroadFinnmark (OF). FL and OF provide interesting conditions for investigating the effects of strenuous physical activity and sleep loss. The aim of this study was to investigate the rest-activity circadian rhythm (RACR) and sleep patterns in mushers and off-road bikers after they participated in the competitions lasting 3- to 7-days. **Methods.** 16 subjects (5 participants at the FL-500km, 5 at the FL-1000km, and 6 bikers in the OF-700km) underwent continuous actigraph monitoring (AW4, CNT) for 5-days before and after the race. The actigraphy data were analyzed by Non-Parametric Circadian Rhythm Analysis (NPCRA), Activity Analysis and Sleep Analysis (Actiwatch Activity and Sleep Analysis software, CNT). The parameters of rest-activity rhythm and sleep quality were analyzed for variance by 2-way ANOVA, and t-test was used for post-hoc analysis. **Results.** In all the races the participants had the chance to sleep for about 3/4-h per day. The long lasting physical activity with fragmented sleep induced a mild phase delay for the athletes of all the races, but a proper free-running effect was not evident. The RACR showed reduced amplitude: there were significant differences between the races, and the reduction was greatest after the race with the largest degree of sleep loss (FL-1000km). The intradaily stability (IS) of the RACR was significantly reduced for the FL-1000km mushers; while the interdaily variability (IV) was significantly increased for the FL-500km mushers, and there was a tendency for the OF-700km bikers. Reduced sleep quality was found only among the FL-1000km mushers. **Discussion and Conclusion.** A period of 3-days of little and fragmented sleep (3-4 hours/per day), in which the subjects were engaged in a prolonged physical effort in intensity zone 1, affected the RACR's structure. A longer period (5/7-days) in such a condition induced even more accentuated alterations, with disturbance in the nocturnal sleep. This induced a sort of vicious circle that made the re-adjustment of the RACR difficult; while increased IV in the 500km mushers and the bikers might indicate a faster re-adjustment.

#### **SURVEY OF INDUSTRY AND CONSUMER VIEWS ON FITNESS**

DJOBOVA, S., DASHEVA, D., PEEVA, P., GEORGIEV, N.

*NATIONAL SPORTS ACADEMY*

**Introduction** The current survey is a part of the European Transfer of Innovation project – № 2009 – BG1-LEO05-01602, funded by the Lifelong Learning Program of the European commission. One of the aims of the project was to perform national need analysis in order to provide an overview of the training needs and the users' requirements in the fitness and health industry. One of the major conclusions of survey performed on the EU health and fitness industry is that the fitness Industry will need a better qualified workforce in the future. In respond to this statement, our effort is focused on transfer, upgrade and creation of program for sport centres employees (Hanna RK, Subic A., 2008). **Methods** The systematic literature review, paper and web-based questionnaires, consultations for obtaining expert opinions, discussions with university authorities have been used. The 200 sports and physical education students and 500 consumers of fitness services were investigated by the specially developed questionnaires based on business requirements for improving employability in the sector. Descriptive statistics were completed to determine the frequencies and percentages. **Results** Organizing and managing the training process in the field of sport for health and recreation (23%) and Planning, programming and organization of sports events, fitness activities and competitions (15%) are the two highly rated skills and abilities from the students. About the consumers the organisational skills also leading (18%) and in the second place is competency connected to the organisation of the training process (17%). For the personal qualities ranking, the students determine the responsible (22%) and easy to make contact (15%) and the consumers also stress the responsibility as a most important personal skill (18%) closely following by communication abilities (17%). **Discussion** The abilities and skills related to all aspects of the training process are ranged as the two most important. On third place is the ability to motivate the clients. This result is correlating with the 'communication' from the personal qualities, which is ranked as second. The other leading personal qualities are responsibility, motivation for professional growth, and team work abilities (Ryan, P. 2003). The results represented show the need of new approach in the design of training programs with greater stress on the training process. **References** 1. Hanna RK, Subic A. (2008). #### **RELIABILITY AND VALIDITY OF ACCELEROMETER DEVICES WHEN USED TO DETECT DIFFERENCES IN ACTIVITY INTENSITY AND ESTIMATE ENERGY EXPENDITURE IN LEAN AND OVERWEIGHT ADULTS.**

KHALID S. ALJALOOD; ADRIENNE R. HUGHES; STUART D.R. GALLOWAY

*KING SAUD UNIVERSITY*

Reliability and validity of accelerometer devices when used to detect differences in activity intensity and estimate energy expenditure in lean and overweight adults. Khalid S. AlJalood, Adrienne R. Hughes, Stuart D.R. Galloway. Health and Exercise Science Research Group,

School of Sport, University of Stirling, FK9 4LA, SCOTLAND, U.K. Introduction: Many devices are available for monitoring of free living physical activity. These devices can detect movement but also posture or physiological variables such as heart rate or heat flux. More information is required on the reliability and validity of these devices under laboratory conditions to judge their value as free living activity monitoring tools. Methods: 61 adults (n= 30 lean and n= 31 overweight/obese) attended for 3 lab sessions. On the first session body mass, height, BMI, body fat and resting heart rate (HR) were recorded, and familiarisation with equipment and procedures was performed. On the 2nd session they were instrumented with three accelerometer devices (ActiGraph, ActivPAL and SenseWear Pro) and then asked to walk on a treadmill at three speeds (3km/h, 4.5km/h and 6km/h) for 5 minutes each at 0% grade. After a 10 min seated recovery period these speeds were replicated on an incline (5% grade). This protocol was repeated on the 3rd session. HR, indirect calorimetry (for energy expenditure determination) and outputs from the three accelerometer devices were recorded throughout. Results: All accelerometers were reliable on the flat and on an incline across all speeds. ActiGraph, ActivPAL and SenseWear Pro gave strong intra-instrument reliability (ICC)  $r = 0.99$ ,  $r = 0.99$  and  $r = 0.96$  all at  $p < 0.001$ , respectively. ActiGraph was valid on more occasions (speeds, gradients) for lean and overweight/obese than the other devices. ActiGraph and SenseWear were able to detect differences in activity intensity between all of the walking speeds on 0% and 5% grade in lean and overweight/obese adults. The ActivPAL was unable to detect differences in activity intensity in overweight/obese adults. All devices had problems with validity of energy expenditure estimates during walking. Conclusion: All of the studied devices are reliable. The ActiGraph and SenseWear Pro were also sensitive enough to detect differences in activity intensity across all speeds examined. ActivPAL could detect differences in activity intensity for lean but not for overweight / obese adults. None of the devices could accurately quantify energy expenditure across all speeds and gradients studied but ActiGraph was considered valid at more speeds on level ground than the other devices. Caution must be taken when using these devices to measure differences in activity intensity or energy expenditure in free living situations, particularly in overweight/obese adults.

### CHANGES OF PHYSIOLOGICAL PARAMETERS IN A SPORTIVE DRUMS ALIVE®-DRUMMING ACTIVITY AND ITS EFFECTS ON CONCENTRATION AND AWARENESS PERFORMANCE

WRIGHT, P., EHNOLD, P., ROSCHMANN, R., WOLF, I.

CHEMNITZ UNIVERSITY OF TECHNOLOGY

Objectives This article will discuss the interim results of a study that investigated a fitness trend that uses elements of drumming and aerobics called Drums Alive®. The focus of the analysis lies on the behaviour of physiological parameters during this intervention in adults of different ages. This should produce information on the typical work intensity of this exercise. Furthermore, the effects on acute concentration and awareness performance after a session of Drums Alive® in students were investigated. The here presented study is part of a bigger project „THE DRUM BEAT – Chemnitz Drumming Project“, which evaluates the possibilities of using this type of drumming exercise in various areas of fitness, education and therapy. Methodology The study design included two sessions to allow the subjects to get used to the movement patterns of Drums Alive® and a third testing session with 27 adults (14 students, 18-22 years and 13 older adults who were between 30 and 65 years of age, described here as AC 30-65). During the testing session physiological data was collected which included heart rate, blood lactate, range of perceived exertion and exemplary spirometry data in two subjects as well as concentration and awareness tests using the d2-test in the students group only (N=16; the d2 students intervention group had two more subjects in this group compared to the physiological data). In order to compare the latter data (concentration performance) a control group of 17 students was used. Results All physiological parameters showed a significant increase compared to the resting values. The intervention can therefore be described as an effective exercise. The blood lactate values showed a mean increase from  $1.16 \pm 0.31$  to  $3.75 \pm 1.91$  [mmol/L] in the overall group (students and AC 30-65, N=27), which corresponds with the changes in heart rate. An increase from  $84 \pm 14$  to  $155 \pm 16$  could be shown. This is also reflected in the high RPE-values of 16 towards the end of the main phase of the Drums Alive® session. The results of the d2-tests showed a slightly better performance in the intervention group (students) compared to the control group, but no significant difference. Conclusions This study proved significant physiological effects in the Drums Alive® exercise session and gave hints on a positive effect on concentration performance. However, more research is necessary before a final statement on the effects of this type of sportive drumming exercise can be given.

### ACCELEROMETER MEASURED PHYSICAL ACTIVITY DIFFERS BETWEEN WRIST AND HIP PLACEMENT SITES IN CHILDREN AGED 10-11 YEARS

ROUTEN, A.C.1, UPTON, D.1, EDWARDS, M.G.2, PETERS, D.M.1,3

1:UW (WORCESTER, UK), 2:UCDL (LOUVAIN, BELGIUM), 3:UJA (KRISTIANSAND, NORWAY)

Introduction The Actiwatch 4 accelerometer (AW4) has been validated as a measure of physical activity (PA) in children (Puyau et al., 2004), however the variance in PA that may be attributable to monitor placement site is not known, despite this being marketed as a wrist worn accelerometer. The purpose was to investigate whether AW4 measured PA counts and time spent in moderate-to-vigorous physical activity (MVPA) differed between the hip and wrist, worn on the dominant and non-dominant sides in children aged 10-11 years. Methods Sixteen boys and 9 girls (Mean  $\pm$  SD Age:  $11.1 \pm 0.5$  ys; Ht:  $141.8 \pm 7.2$  cm; Wt:  $37.5 \pm 8.5$  kg; BMI:  $18.6 \pm 3.3$  kg/m<sup>2</sup>) wore an AW4 on the dominant hip (DH), non-dominant hip (NDH), dominant wrist (DW) and non-dominant wrist (NDW) for 4 hours during a school day, including recess and lunchtime. Side dominance was assessed through writing preference. Mean PA counts (counts/10sec), and minutes of MVPA using hip derived cut-off's derived by Puyau et al., (2004) were calculated. Results One-way repeated measures ANOVA, revealed a significant placement effect for mean PA counts ( $F(1.5, 30.6) = 53.6$ ,  $p = 0.01$ , partial  $\eta^2 = 0.72$ ) and minutes of MVPA ( $F(1.9, 39.0) = 109.5$ ,  $p = 0.01$ , partial  $\eta^2 = 0.84$ ). Post hoc paired t-tests with Bonferroni correction revealed differences between DH and DW ( $85.6 \pm 50.5$  vs.  $154.5 \pm 42.2$  counts/10sec, 95% CI:  $-89.1$  to  $-48.6$  counts/10sec,  $p = 0.01$ ,  $d = -1.5$ ;  $55.3 \pm 24.0$  vs.  $100.3 \pm 26.9$  mins, 95% CI:  $-54.5$  to  $-35.6$  counts/10sec,  $p = 0.01$ ,  $d = -1.7$ ) and NDH and NDW ( $85.0 \pm 44.7$  vs.  $147.0 \pm 37.6$  counts/10sec, 95% CI:  $-74.4$  to  $-49.6$  counts/10sec,  $p = 0.01$ ,  $d = -1.5$ ;  $54.3 \pm 22.9$  vs.  $99.0 \pm 23.3$  mins, 95% CI:  $-50.2$  to  $-39.1$  counts/10sec,  $p = 0.01$ ,  $d = -1.9$ ). No differences in mean PA counts or minutes of MVPA were found between DH and NDH or DW and NDW ( $p > 0.05$ ). Discussion Neither mean PA counts nor minutes of MVPA differed between the D and ND placement at either the wrist or hip which is consistent with previous data in other devices (Van Hilten et al., 1993) and shows that side dominance is not an important monitoring issue. Wrist measured PA counts and minutes of MVPA were, however, considerably greater than those derived from the hip. Physical activity data derived from wrist and hip placements are therefore not comparable and further investigation is required to develop suitable cut-off points for wrist measured physical activity if such devices, which are inherently more participant friendly, are to be used in future physical activity research. ## PILOT STUDY OF THE FITNESS SERVICE QUALITY DELIVERY

DASHEVA, D., DJOBOVA, S., PEEVA, P., GEORGIEV, N.

NATIONAL SPORTS ACADEMY

**Introduction** This pilot study is a part of the European Transfer of Innovation project – № 2009 – BG1-LEO05-01602, funded by the Liveling Learning Program of the European commission. One of the aims of the overall project was to perform national need analysis in order to provide an overview of the training needs and the users' requirements in the fitness and health industry. Yet the lack of studies regarding the status of the health and fitness industry of Bulgaria such as the credentials of education and certification of the fitness professionals surges the fitness industry into the unknown. The purpose of this study was to investigate the clients' opinion about the quality of fitness services. **Methods** The web-based questionnaire and interview with open-ended questions have been used. The 500 consumers of fitness services from more than 120 fitness centers were investigated. Descriptive statistics were completed to determine the frequencies and percentages. Results 32% from the surveyed chooses the fitness venue from the quality of the equipment following by the abilities of the instructors (20%) and quality of services offered (16%). At the same time 32% from the clients are not interested at all of the qualification of the instructors and 28 % are absolutely sure that their instructors are not certified. In the same time clients stress on the professional qualification as being the most important factor (35%). **Discussion** The findings of the study demonstrate that although the industry seems to be in a rapid growth phase, there are problems that would not allow the future success of the industry (Sekendiz, B., 2005). The consumers underestimate the credentials of the fitness professionals and at the same time quickly withdraw if their goals are not met. The industry lacks standardization, and regulations are not adequate to save it from abuse (McDonnell, A. B. (2004). Although the Bulgarian health and Fitness Association emerged as the major certification body, it holds less than 1/3 of the industry. The major part of the Fitness centers does not meet the national and European standards. Base on the findings, the clients must be more demanding towards their fitness instructors. In turn this will motivated the instructors and fitness centers itself to be certified. In general this will improve the quality of Fitness industry in Bulgaria. **References** 1. McDonnell, A. B. (2004). Retention: It's All About Customer Service. *Fitness Management*. Retrieved on March 10, 2004. 2. Sekendiz, B. (2005). ## INTERNET-BASED VERSUS PRINT-BASED BEHAVIORAL INTERVENTION FOR PHYSICAL ACTIVITY PROMOTION AMONG UNIVERSITY STUDENTS – A RANDOMIZED CONTROLLED TRIAL

LEUNG, E., WONG, S., HUANG, W.

THE CHINESE UNIVERSITY OF HONG KONG

**Background:** A considerable proportion of university students cannot meet the recommendation criteria for physical activity (PA) (Seo et al., 2007). Most university students are familiar with computer use; the Internet may have the potential for delivering behavioral program for PA promotion. **Purpose:** The study examined the effectiveness of using Internet to a deliver behavior change program for PA promotion among the university students. **Methods:** A total of 111 Hong Kong university students were randomly assigned to one of the three groups, i.e. the Internet-based group (IB), print-based group (PB), and control group (C). Participants of the IB group received the online behavior change program entitled "Active Living Every Day (ALED)" (Blair et al., 2001). Participants of the PB group received the same program through face-to-face classes. Participants of group C did not receive any intervention treatment. The assessment of PA level and meeting the ACSM criteria of sufficient PA were carried out at baseline, 3rd month and 6th month. Results: Increased in PA ( $P < 0.05$ ) was found in the print-based and Internet-based groups at the 3rd and 6th month assessments. Increased in the proportion of participants meeting the ACSM criteria of sufficient PA was found in the IB group at the 3rd month assessment **Conclusion:** Internet-based PA programs may be an effective channel for promoting PA among university students. **References:** Blair, S. N., Dunn, A. L., Marcus, B. H., Carpenter, R. A., & Jaref, P. (2001). Active living every day: get active with a 20-step program. *Human Kinetics*, Champaign, IL. ## VALIDITY OF THE ACTISmile WORN AT TWO MEASUREMENT SITES

MÄDER, U., HÄNGGI, J., ROOS, L., RUCH, N.

FEDERAL OFFICE OF SPORTS

**Introduction** The aim of the present study was to validate the measurement characteristics of a device that gives the user a feedback in terms of performed health-enhancing physical activity (HEPA). **Method** The ActiSmile (Actismile, Bern-Liebefeld, Switzerland) is a device that measures time spent walking and running and classifies it as HEPA and assigns the remaining time to non-active time. The integrated monitor gives a feedback to the user in terms of a smiley whether the minimum of the recommended amount of HEPA (1,2) is achieved. Five women ( $39.9 \pm 15.3$  y,  $169.5 \pm 47.4$  cm,  $63.3 \pm 18.8$  kg) and six men ( $41.1 \pm 12.2$  y,  $180.3 \pm 7.4$  cm,  $81.3 \pm 10.5$  kg) participated in the study. They wore one ActiSmile on a belt at the hip (AS-hip) and one in the trouser pocket (AS-pocket). The following six activities were performed: moderate and fast level walking, moderate walking uphill and downhill, level running and level biking. All activities were performed for 3 min and 25 s: as the ActiSmile records only one-minute activity blocks, i.e. blocks of 60 s, this allows some tolerance at the beginning and ending of the activities. Data of the ActiSmile was downloaded after every single activity to determine the proportion of time recognised as walking, running or non-active time. Recognition rates of the device worn at the hip and the one carried in the trouser pocket were compared using a Chi2-test. Another bout of moderate level walking was performed for 5 min to validate the smiley that is given at the achievement of the HEPA recommendation. The amount of time until the smiley appeared was measured and compared to the 5-min level by a Wilcoxon-signed-rank-test. **Results** Recognition rate of moderate level walking was 100% and 97% in the AS-hip and the AS-pocket, respectively. Recognition rate of walking uphill (downhill) was 100% (100%) and 96% (87%) in the AS-hip and the AS-pocket device, respectively. 10% of walking downhill was assigned to running activities by the AS-pocket. 96% (AS-hip) and 84% (AS-pocket) of fast walking was assigned to walking. 4% (AS-hip) and 12% (AS-pocket) of fast walking was assigned to running activity. 87% and 86% of running was assigned to running activity, 10% and 14% to walking activities by the AS-hip and the AS-pocket, respectively. There were no significant differences between the two devices in all activities ( $p > 0.05$ ). The smiley appeared after 4 min 59 sec  $\pm 11$  sec. There was no significant difference to the 5 min level after which the smiley should appear. **Discussion** The ActiSmile is a small and easy manageable feedback device that measures precisely time spent in continuous walking and running when worn at the hip or in a trouser pocket. It gives the user a valid feedback on the achievement of HEPA recommendations. **References** (1) Pate RR et al. Physical activity and Public

Health. *Jama*, 273 (5), 402-07,1995. (2) Martin BW et al. Physical activity and health – what are the recommendations and where do we find the Swiss population? *Schw. Z. Sportmed. Sporttraumat.* 57 (2), 37 -43, 2009.

### INTRA- AND INTER-INSTRUMENT RELIABILITY OF THE ACTIWATCH 4 ACCELEROMETER IN A MECHANICAL LABORATORY SETTING

ROUTEN, A.C.1, UPTON, D.1, EDWARDS, M.G.2, PETERS, D.M.1,3

1:UW (WORCESTER, UK), 2:UCDL (LOUVAIN, BELGIUM), 3:UJA (KRISTIANSAND, NORWAY)

**Introduction** The Actiwatch 4 (AW4) has been proposed as a valid measure of physical activity in children (Puyau et al., 2004), yet no studies have investigated its reliability. The purpose was to investigate in the AW4 in a controlled mechanical setting, the intra- and inter-instrument reliability of mean physical activity counts and time spent in moderate (MPA), vigorous (VPA), and moderate-to-vigorous physical activity (MVPA), which is the most frequently employed outcome in physical activity epidemiology studies in children (Janssen and LeBlanc, 2010). **Methods** Twenty seven AW4 were attached to an isokinetic dynamometer (Computer Sports Medicine Inc., Stoughton, MA, US) and subjected to constant speed angular movement for 30 mins at 50 deg/sec representing MPA (Condition A) & 200 deg/sec representing VPA (Condition B), with a repeat trial conducted. Reliability was assessed using coefficient of variation (CV), absolute percent error (APE), and intraclass correlation coefficients (ICC). Results Mean physical activity counts displayed acceptable reliability according to CV in both conditions, however the APEinter in Condition A was greater than the inter-unit threshold of 5% suggested by Esliger & Tremblay (2006) (A: CVintra=4.6%, APEintra=6.6%, CVinter=6.4%, APEinter=5.2%; B: CVintra=3.9%, APEintra=5.6%, CVinter=5.9%, APEinter=4.7%). Time spent in MPA and VPA displayed better reliability with low CV values observed and APEinter values of <5% (A: CVintra=3.2%, APEintra=2.3%, CVinter=4.3%, APEinter=3.2; B: CVintra=0.0%, APEintra=0.0%; CVinter=0.0%; APEinter=0.0%). Time spent in MVPA displayed excellent reliability (CVintra, APEintra, CVinter, & APEinter=0.0%) in both conditions. Discussion Mean AW4 activity counts exhibit reliability statistics that are comparable to other accelerometers (Esliger & Tremblay, 2006). Reliability is improved when activity counts are categorised as time spent in MPA and VPA, with MVPA displaying the greatest reliability. As MVPA is the subcomponent of physical activity most associated with health benefits in children (Janssen and LeBlanc, 2010), it would appear that the Actiwatch 4 is a reliable accelerometer for measuring time spent in this health enhancing physical activity category, at least from testing in a mechanical laboratory setting. STATE UNIVERSITY OF LONDRINA, SPONSORED BY ARAUCARIA FOUNDATION

**CRITERIA FOR USE OF PHYSICAL BEST AND FITNESSGRAM FOR ANALYSIS OF BODY MASS INDEX AND AEROBIC FITNESS IN CHILDREN AND ADOLESCENTS** Oliveira, AR.1,2, Arruda, GA.1,3, Greca, JPA.1, Neri, FS.1, Cabral, L.I, Teixeira, M.1, Pires Jr, R.1 1: UEL (Londrina, Brazil), 2: CNPq, 3: CAPES (Brasilia, Brazil) **Introduction** The aim of this study was to assess the agreement between the criteria of the Physical Best (AAHPERD, 1988) and Fitnessgram (Meredith; Welker, 2004) for the Body Mass Index (BMI) and 1600m Run/Walk according to gender. **Methods** The subjects belonged to the same elementary school in Londrina (Parana, Brazil) and the Perobal Project at the State University of Londrina, a partnership with the Ayrton Senna Institute/AUDI:AG, Sao Paulo-SP. The sample involved 73 individuals, 39 boys 12.66 (1.56) years old; body mass 42.21 (13.22) kg, height 149.84 (9.82) cm; and 34 girls 12.34 (1.57) years, body mass 46.97 (12.60) kg, height 150.45 (7.99) cm. Only 43 participated in the Walking/1600 m run (N=73), with 23 boys 12.12 (1.47) years, body mass 42.24 (15.66) kg, Height 147.42 (9.37) cm; and 20 girls, 11.79 (1.41) years, body mass 45.17 (13.44) kg, height 148.30 (7.64) cm. Body mass and height were measured according to Gordon et al (1988) and calculated the BMI. The cardiorespiratory function was assessed through the walk/1600m (AAHPERD, 1988). The Kolmogorov-Smirnov test was used to analyze the distribution of variables. Mean and standard deviation were used to characterize the sample. The agreement level was evaluated by the percentage. Results The BMI mean was 18.55 (4.29) kg/m<sup>2</sup> in boys and 20.53 (4.26) kg/m<sup>2</sup> for girls. The mean time for the Run/Walk test was 12.32 (1.86) min. for boys and 14.77 (2.36) min. for girls. The BMI propositions agreed in 76.9% of cases for boys. Among the 74.4% of subjects who responded to the Physical Best 23.1% did not attend the Fitnessgram. The propositions mutually classified 70.6% of cases for girls. The 76.5% who attended the Physical Best 20.6% did not attend the Fitnessgram. Propositions classified in agreement 78.3% of individuals in the Run/Walk 1600m test. Among the 21.7% that met the criterion on the Fitnessgram no one attended the Physical Best. The proposals agreed on 100% of cases. Only 5% of girls met both criteria, and 95% did not attend any of the criteria. Discussion The proposals seem to agree on the predominant part of cases for both BMI (> 76.5%) and for aerobic fitness (> 78.3%). However for the BMI cutoff points of Fitnessgram were responsible for a higher proportion of non-attendance and the Run/Walk 1600 m test cutoff points of Physical Best. The use of different cutoff points for the same individual should be used with caution especially for the morphological component. ### VALIDITY OF THE ACTISmile WORN AT TWO MEASUREMENT SITES BY CHILDREN

RUCH, N., JOSS, F., HÄNGGI, J., MÄDER, U.

FEDERAL INSTITUTE OF SPORT

**Introduction** The aim of the present study was to validate the ActiSmile (Actismile, Bern-Liebfeld, Switzerland), a device that gives feedback to the user in terms of physical activity (PA) for children. **Method** The ActiSmile is a device that measures time spent in walking and running. The remaining time is classified as no activity. Nine children (7 girls and 2 boys, 8.8 ± 2.9 y, 1.38.1 ± 0.25 cm, 33.4 ± 13.7 kg) participated in the study. They wore one ActiSmile on a belt on the hip (hip device) and one in the trouser pocket (pocket device) except for biking, where the pocket device was moved into the sock of the subject. Five activities were performed such as moderate and fast level walking, moderate running, kickboarding and level biking. All activities were performed for 3 min and 25 s: as the ActiSmile records only one-minute activity blocks, i.e. blocks of 60 s, this allows some tolerance at the beginning and ending of the activities. Data of the ActiSmile was downloaded after every single activity to determine the proportion of time recognised as walking, running or no activity. Recognition rates of the two devices were compared using a Chi2-Test. Results Recognition rate of moderate level walking was 97% in the hip

device and the pocket device, respectively. Fast walking was mainly assigned to walking (hip device: 63%, pocket device: 75%) whereas a smaller part was assigned to running activity (hip device: 33% and pocket device 18%). The remaining time was classified as no activity. 79% and 72% of running was assigned to running activity, 14% and 21% to walking activities. The remaining time was assigned to no activity by the hip and the trouser device, respectively. 96% (hip device) and 100% (pocket device) of the activity kickboarding was assigned to walking. 6% was classified as no activity by the hip device. 90% of biking was classified as walking by the pocket device whereas the hip device classified 48% as walking. 52% (7%) of biking was assigned to no activity by the hip (pocket) device. A significant difference between the two devices was not found for any activity. Discussion The ActiSmile measures precisely time spent in continuous walking and running when worn on the hip or in a trouser pocket. It classifies frequent children-specific activities such as kickboarding and biking mainly as walking. Conclusion The ActiSmile is a small and easy manageable feedback device for children that recognises not only walking and running activities. It is able to identify other children-specific activities such as biking and kickboarding as moderate activities by assigning them to the activity walking.

#### UTILIZATION OF WORK RATE INCREMENT AS IMPORTANT PARAMETER OF AEROBIC FUNCTION DURING INCREMENTAL TREADMILL EXERCISE

IM, J.1, JEON, Y.2, KIM, D.3, KANG, Y.4, AHN, M.5, KIM, C.6, KIM, B.7

1,2,3,4,5:KAIST(S.KOREA), 6,7:DAEJEON U.(S.KOREA).

In this study, we verify  $VO_{2\text{gain}}(\Delta VO_2/\Delta \text{work rate})$  is useful parameter which can determine aerobic capacity through finding close correlation with Anaerobic Threshold( $AnT$ ) and Maximal Oxygen Uptake( $VO_{2\text{max}}$ ). As a result of this study, we certain that  $VO_{2\text{gain}}$  can be alternative variable for  $AnT$  and  $VO_{2\text{max}}$ , and also  $VO_{2\text{gain}}$  can be important mediator of regression equation for  $AnT$  or  $VO_{2\text{max}}$  estimation. For this way, we don't need to do further exercise testing for obtaining accurate  $AnT$  and  $VO_{2\text{max}}$ . Thirty seven male college students performed incremental treadmill exercise test. We derived regression equations and found significant correlations of  $VO_{2\text{max}}$  with  $VO_{2\text{gain}}$  ( $VO_{2\text{gain}} = 0.064(VO_{2\text{max}})+33.201$ ,  $SEE=\pm 23.35$ ,  $r=0.843$ ,  $P<0.01$ ),  $\Delta VO_2(VO_{2\text{gain}}(EE-3rd \text{ min}) = 0.068(VO_{2\text{max}})+32.717$ ,  $SEE=\pm 29.27$ ,  $r=0.801$ ,  $P<0.01$ ), and  $\Delta VO_2(VO_{2\text{gain}}(EE-6th \text{ min}) = 0.087(VO_{2\text{max}})+15.536$ ,  $SEE=\pm 59.68$ ,  $r=0.641$ ,  $P<0.01$ ). By analyzing relationship between  $VO_{2\text{gain}}$  and  $VO_2$  at  $AnT$ , we found brilliant correlation between them ( $VO_{2\text{gain}}=0.077(VO_2 \text{ at } AnT)+68.46$ ,  $SEE=\pm 29.65$ ,  $r=0.730$ ,  $P<0.01$ ). For these reasons,  $VO_{2\text{gain}}$  can widely use with other variables in oxygen uptake kinetics such as  $AnT$  and  $VO_{2\text{max}}$ . Finally we conclude  $VO_{2\text{gain}}$  has significant reliability in oxygen uptake kinetics.

#### ACUTE SUPPLEMENTATION WITH LEUCINE REDUCES A MARKER OF SKELETAL MUSCLE DAMAGE IN UNTRAINED RATS SUBJECTED TO AN ACUTE BOUT OF EXERCISE TO EXHAUSTION

PAULA, T.D.1, PANTALEÃO, L.C.2, LOPEZ, L.1, TIRAPEGUI, J.1

1: FCF – USP (SÃO PAULO, BRAZIL), 2: ICB – USP (SÃO PAULO, BRAZIL), UNIVERSITY OF SÃO PAULO

Introduction Recent studies have associated unusual high intensity physical exercise with subsequent muscle injuries. In this regard, amino acid supplementation stands out as an effective strategy in controlling cell damage, and researchers have demonstrated the potential of branched chain amino acids (BCAA) supplementation in reducing the extent of damage, and promoting muscle recovery (Anthony et al., 1999). As leucine plays an important role in regulating anabolic mechanisms stimulating the rate of mRNA translation mediated by the protein kinase mTOR (Anthony et al., 2001; Kimball e Jefferson, 2006), it is speculated what would be the possible effects of exclusive leucine supplementation in a model of strenuous and unusual physical activity. Thus, the aim of the present study is to evaluate the effect of leucine supplementation on serum creatine kinase levels – a marker of muscle damage – and on phosphorylation of proteins involved in mTOR pathway in the skeletal muscle of untrained adult rats subjected to an exercise session to exhaustion. Methods Therefore, 17 male adult Sprague-Dawley rats were divided into two groups receiving supplementation with either leucine (135 mg/100 g) or a mix of non-essential amino acids (43.35 mg/100 g) at the end of a session of acute exercise. The animals were killed 3 hours after the exercise session for blood sampling and excision, freezing and storing of skeletal muscle samples. Creatine kinase levels were obtained by spectrophotometry using a commercial kit and the protein phosphorylation was quantified by Western Blotting. Results We observed a significant reduction on serum creatine kinase levels in response to leucine supplementation. However, no effect was observed in the phosphorylation of mTOR, 4E-BP1 and S6K1. Discussion Stock et al., (2010) examined the effects of adding leucine to pre and postexercise carbohydrate beverages on selected markers of muscle damage and conclude that the leucine supplementation didn't reduce serum creatine kinase levels, but we observed that leucine supplementation caused a possible reduction on muscle damage in untrained rats subjected to acute exercise and, as no change was observed in mTOR activity, this effect does not seem to be associated with this pathway. #### SHORT-TERM EFFECTS OF BCAA, ARGININE AND CLA SUPPLEMENTATION ON REST ENERGY EXPENDITURE AND BODY COMPOSITION.

SPONSIELLO, N.,TAMBURO, S.

CAMERINO UNIVERSITY; ITALIAN SOCIETY OF SPORT NUTRITION AND WELLNESS

Background – Previous works assumed that the BCAA (branched- chain amino acids), L- arginine and CLA (conjugated linoleic acid) supplementation may affect rest energy expenditure (REE) and the decrease of fat rate.1,2,3,4 This study aims at testing whether these substances can actually increase rest energy expenditure and improve body composition. Methods and results – 25 healthy volunteers, aged 18-44 years have been tested. (Twenty-two men and three women among athletes, sportsmen/sportswomen, sports-practicing subjects and inactive subjects: in general all active). All subjects started a normocaloric and balanced diet 1 week before the first calorimetry test, keeping it on till the 2° test. They began the supplementation with two products available in the market: X-Treme CLA and X-

Treme NOX, (Inkospor Italy Ltd). One, CLA, contains conjugated linoleic acid and the other, NOX, contains branched-chain amino acids, arginine, green tea extracts, caffeine and vitamin C. Volunteers have been given the above mentioned integrators for two weeks. Rest energy expenditure (REE kcal/day), free mass rate (FFM %), fat mass rate (FM %), body weight (Kg) and BMI (Kg/m<sup>2</sup>), have been monitored before and after the two week cycle. Results - The supplementation intake has led to significant results as it follows: (\*p<0,005) (-1,24%) body weight, BMI (-1,25%), FM (-4,28%) and FFM(+1,07%). The REE hasn't led to significant results (p=0,0179) despite a 10,9 % increase. Beyond the results we need to highlight that six subjects were excluded from the REE average as the tests were not reliable for different reasons. Discussion - The results about REE and slight variations on body composition due to the two supplements intake are consistent with this study. We are convinced that the action of the ingredients taken singularly is not clear/evident. Even if the calorific increase of rest energy expenditure (REE) is slight, we think that it can help subjects control their weight. The combination between balanced diet and adequate physical activity may benefit the fat mass decrease and the improvement of body composition in sportsmen and inactive subjects. Even though the results are encouraging, medium- and long- term studies on these data are required in particular on rest energy expenditure and its variables affecting calorimetry. Introduction Prolonged physical exertion may lead to post exercise suppression of mucosal immune parameters. We investigated the effect of astaxanthin (Asx) supplementation on salivary IgA (sIgA) responses in young soccer players following 2 hours of forced training. Methods 35 soccer players (age 17.9±0.72 years), were randomly divided into 2 groups: astaxanthin (Asx) and placebo (P) group. The Asx group was supplemented with 4 mg of Asx. Saliva samples were obtained before and after the forced training. We have done analysis before, after 45 and after 90 days of supplementation. Saliva samples were analyzed for sIgA concentrations by ELISA test. sIgA secretion rate (mg/min) was determined by multiplying the absolute sIgA concentration (mg/ml) with saliva flow rate (ml/min). Results: In the pre-supplemental period training induced significant decrease in sIgA concentration and sIgA secretion rate in young elite soccer players (p<0.05). Significant pre- to post-training decrease in sIgA concentration and sIgA secretion rate was also observed after 45 and 90 day of supplementation in both Asx and P group (p<0.05). However, significant effect of Asx supplementation was observed in pre-training sIgA concentrations and sIgA secretion rate. In Asx group, these parameters remained unchanged after 45 days of supplementation, but increased significantly over the remaining time (p<0.05). In P group, we detected decrease in sIgA response after 45 days and 90 days of observational period, but without statistical difference. Conclusion: Asx supplementation did not attenuate exercise-induced decrease in sIgA response. However, increase in resting IgA concentrations and sIgA secretion rate in Asx group suggest that the astaxanthin supplementation could improve mucosal immunity after a minimal period of 90 days of regular taking of Asx. Glesson M, Pyne D. (2000). Immunology and Cell Biology, 78, 536–544. Higuera-Ciapara I, Félix-Valenzuela L, Goycoolea F. (2006) Critical Reviews in Food Science and Nutrition, 46(2), 185-196.

## BRANCHED-CHAIN AMINO ACID SUPPLEMENTATION ON EXERCISE-INDUCED MUSCLE DAMAGE: A PILOT INVESTIGATION

HOWATSON, G., HOAD, M., GOODALL, S., TALLENT, J., BELL, P., FRENCH, D.N.

NORTHUMBRIA UNIVERSITY

Introduction Branch chain amino acids (BCAA) are a substrate for protein synthesis and have been shown to conserve muscle mass and be beneficial to conditions characterised by protein loss and catabolism (1). Evidence suggests BCAA to be of benefit in recovery from heavy endurance activity (3). However only one investigation (2) has examined the efficacy of BCAA following a damaging bout of eccentrically biased resistance exercise that was designed specifically to cause temporary muscle damage; this was conducted with untrained individuals using an isolated muscle group. Therefore the aim of this study was investigate the effect of BCAA supplementation on recovery from a damaging bout of sport specific eccentrically biased exercise in resistance-trained individuals. Methods Twelve volunteers were supplemented with either 20 g of BCAA or placebo for 7 days prior to, and 4 days following a damaging bout of eccentric biased exercise in a double blind, randomized trial. Additional BCAA or placebo (20 g) was administered before and following the exercise. The damaging bout consisted of 100 drop-jumps from a 60 cm platform. Indices of muscle damage; creatine kinase (CK), maximum isometric voluntary contraction (MVC), vertical jump (VJ), muscle soreness (DOMS) and thigh and calf limb girth were taken pre-exercise, 24, 48, 72 and 96 h post-exercise. Results There was significantly less CK (P = 0.028; 95% CI – 5-67 IU/L) and DOMS (P < 0.001; 95% CI – 11-32 mm) in the BCAA group). In addition, the decrement in MVC was less (73% vs. 82%) in the BCAA group (P = 0.01; 95% CI – 1.4-8.4%). There were no differences between groups for VJ, or limb girth. Discussion Twelve days of BCAA supplementation taken before and following a damaging bout of heavy plyometric exercise provides a protective effect from the negative signs and symptoms of muscle damage. Although the mechanisms of action are not fully understood, it has been postulated that BCAA supplementation modulates protein and/or the secondary inflammatory process associated with heavy exercise (1). Our observations support others (2,3) that demonstrated a positive effect with BCAA supplementation following heavy exercise. The current data extend this knowledge to support the efficacy of BCAA supplementation before and following high intensity plyometric exercise. References 1. ## READINESS TO INVEST EFFORT IS AUGMENTED FOLLOWING INGESTION OF A CAFFEINE CONTAINING ENERGY DRINK PRE AND POST RESISTANCE EXERCISE

DUNCAN, M., STANLEY, M.I., PARKHOUSE, N.I., SMITH, M.I., COOK, K.

COVENTRY UNIVERSITY

**Introduction** Recent research has suggested that there is a need to examine the effects of caffeine containing supplements on resistance exercise performance (Beck et al., 2008) and that scientists examine psychological variables, such as readiness to invest effort, alongside performance with caffeine ingestion (Astorino and Roberson, 2010). The aim of this study was to examine the effect of a caffeine containing energy drink 'Quick Energy' on repetitions to failure and readiness to invest effort pre to post resistance exercise. **Methods** Following ethics approval and informed consent, 11 resistance trained individuals underwent assessment of 1 repetition maximum testing (1RM) in the bench press, deadlift, barbell row and back squat. Participants then completed two trials (caffeine and placebo) separated by 72 hours and 72 hours post 1RM testing. Participants ingested solutions containing 'Quick Energy', an energy drink containing 125mg caffeine or a placebo diluted into 250ml artificially sweetened water in a double blind, randomised order. 60mins post ingestion, participants completed a resistance exercise session comprising of repetitions to failure at 60%1RM in each of the 4 exercises separated by 5mins rest. Prior to ingestion, prior to exercise and post exercise participants also completed measures of readiness to invest physical (RTIPE) and mental (RTIME) effort (Tenenbaum et al., 2001). **Results** Participants completed significantly more repetitions to failure and reported significantly greater RTIME ( $P = .05$ ) in the presence of caffeine compared to placebo ( $P = .05$ ). A significant solution X time interaction ( $P = .05$ ) for RTIPE indicated a greater increase in RTIPE pre ingestion to pre exercise and higher RTIPE post exercise in the presence of the caffeine containing energy drink compared to placebo ( $P = .05$ ). **Discussion** These results support prior claims that caffeine containing supplements can enhance resistance exercise to failure (Beck et al., 2008). This study indicates consumption of a caffeinated solution also resulted in greater readiness to invest effort, agreeing with prior data (Tenenbaum et al., 2001). In this case of RTIPE, ingestion of caffeine not only resulted in increased RTIPE before exercise but also a smaller decline in RTIPE post resistance exercise compared to placebo. The results of the present study suggest that consuming the energy drink 'Quick Energy' can augment readiness to invest effort over consumption of a placebo solution pre and post exercise. **References** Astorino TA, Roberson DW. (2010). J Strength Cond Res, 24, 257-265. Beck TW, Housh TJ, Malek MH, Mielke M, Hendrix R. (2008). J Strength Cond Res, 22, 1654-1658. Tenenbaum G, Hall HK, Calagnini K. (2001). ## THE EFFECT OF A CAFFEINE CONTAINING ENERGY DRINK 'QUICK ENERGY' ON REPETITIONS TO FAILURE, PERCEIVED EXERTION AND PAIN PERCEPTION FOLLOWING RESISTANCE EXERCISE

DUNCAN, M.J.I., STANLEY, M.I., PARKHOUSE, N.I., SMITH, M.I., COOK, K.I.

COVENTRY UNIVERSITY

**Introduction** The effect of caffeine on endurance performance is well reported but less research is available in relation to resistance exercise performance (Duncan and Oxford, 2011). Research has suggested that scientists examine the effect of caffeine containing supplements on multiple resistance exercises rather than examining one exercise only as is common (Duncan and Oxford, 2011). The aim of this study was to examine the effect of a caffeine containing energy drink 'Quick Energy' on repetitions to failure, perceived exertion and pain perception following a bout of resistance exercise. **Methods** Following ethics approval and informed consent, 11 resistance trained individuals underwent assessment of 1 repetition maximum testing (1RM) in the bench press, deadlift, barbell row and back squat. They then completed two trials (caffeine and placebo) separated by 72 hours. Participants ingested solutions containing 'Quick Energy', an energy drink containing 125mg caffeine or a placebo diluted into 250ml artificially sweetened water in a double blind, randomised order. One hour post ingestion, participants completed a resistance exercise session comprising of repetitions to failure at 60%1RM in the 4 exercises separated by 5mins rest. Rating of perceived exertion (RPE) and pain perception were assessed following each exercise using the Borg (1970) 6-20 scale and Cook (1998) pain scale. **Results** Participants completed significantly more repetitions ( $P = .02$ ) and RPE was significantly lower in the caffeine condition compared to placebo ( $P = .002$ ). Irrespective of solution ingested, RPE was lower ( $P = .001$ ) for upper body compared to lower body exercises. Pain perception was also lower with caffeine compared to placebo ( $P = .001$ ). **Discussion** These results support claims that caffeine ingestion enhances resistance exercise to failure and dampens RPE (Duncan and Oxford, 2011). In this case the dose of caffeine ingested, in the form of an energy drink, was lower than doses previously found to be ergogenic (Astorino and Roberson, 2010). Prior research has also suggested caffeine ingestion reduces pain perception during aerobic exercise (Cook et al., 1998). The current study supports suggestions (Astorino and Roberson, 2010), that this is also the case for resistance exercise. The results of the present study suggest that consuming the energy drink 'Quick Energy' results in enhanced resistance exercise performance and dampened perceptions of pain and exertion. **References** Astorino TA, Roberson DW. ## EFFECTS OF CAFFEINE, SODIUM BICARBONATE AND THEIR COMBINED INGESTION ON HIGH-INTENSITY CYCLING PERFORMANCE

KILDING, A.E., OVERTON, C., GLEAVE, J.

AUT UNIVERSITY

**EFFECTS OF CAFFEINE, SODIUM BICARBONATE AND THEIR COMBINED INGESTION ON HIGH-INTENSITY CYCLING PERFORMANCE** Kilding, A.E., Overton, C. and Gleave, J. Sport Performance Research Institute New Zealand, AUT University, Auckland, New Zealand **Introduction** In recent years, the practice of consuming potentially performance enhancing nutritional ergogenic aids by athletes has become increasingly prevalent. Previous studies have documented that caffeine and sodium bicarbonate, amongst other substances, can enhance exercise performance (e.g. Jenkins et al 2008; Requena et al 2005). However, research considering the effects of simultaneous ingestion of caffeine and sodium bicarbonate prior to high-intensity exercise is limited (Pruscino et al 2008). Thus, the aim of the present study was to compare the effects of ingesting caffeine and sodium bicarbonate on 3 km laboratory time trial (TT) performance when taken individually and simultaneously. **Methods** Adopting an acute, double-blind, crossover design, 10 well-trained cyclists (age  $24.2 \pm 5.4$  yrs) completed four 3 km TT's on a laboratory-based cycle ergometer. At specific times prior to each TT, participants ingested either: 3 mg/kg body mass (BM) of caffeine (CAFF); 0.3 g/kg BM of sodium bicarbonate (SB); a combination of both (CAFF+SB); or a placebo (PLAC). Prior to and during each 3 km time trial, physiological, perceptual, and performance measurements were determined. **Results** In CAFF, SB, and CAFF+SB, mean power output during 3 km TT's was improved compared to PLAC (2.4, 2.6, and 2.7% respectively), resulting in a faster

time to completion (-0.9, -1.2, and -1.2% respectively). Effects sizes (ES) for all trials were similar (0.21 to 0.24). A significant increase in post-TT blood lactate, pH, and NaHCO<sub>3</sub> was noted in SB and in CAFF+SB when compared to CAFF and PLAC trials ( $P < 0.05$ ). No significant differences between conditions were observed with regards to perceived gastric discomfort ( $P < 0.05$ ). Discussion When ingested individually, both caffeine and sodium bicarbonate enhanced high-intensity exercise performance in trained cyclists. However, simultaneously ingesting caffeine and sodium bicarbonate prior to high-intensity exercise trials did not further enhance the ergogenic effect and therefore this practice is not recommended. ### GLYCEROPHOSPHOCHOLINE INTAKE ENHANCES GROWTH HORMONE SECRETION AND FAT METABOLISM IN YOUNG SUBJECTS

KAWAMURA, T.1, SATO, K.1, FUJITA, S.1, OKUBO, T.2, HIBINO, H.2, GOTO, K.1, HAMAOKA, T.1, IEMITSU, M.1

1: FACULTY OF SPORT AND HEALTH SCIENCE, RITSUMEIKAN UNIVERSITY, SHIGA, JAPAN., 2: NOF CORPORATION, KANAGAWA, JAPAN.

Background: Choline is an important nutrient, which relates to cholinergic neuronal action as well as fat and cholesterol metabolism. Since choline is not synthesized in vivo, it needs to be ingested from food, such as beans and eggs. Glycerophosphocholine (GPC) synthesized from bean, has been used for medicines and supplement. GPC is a putative acetylcholine precursor, which could potentially enhance growth hormone (GH) secretion through acetylcholine-induced catecholamine. Purpose: The primary aim of the study was to clarify whether an acute intake of GPC enhances GH secretion. Furthermore, the secondary aim of the study was to investigate whether GPC-induced change in GH secretion concomitantly affects fat metabolism in the liver. Methods: To reveal GH and fat metabolism responses by an acute intake of GPC, eight healthy male ( $25 \pm 1$  years) subjects participated in the study. Fasting blood samples were obtained before and additional samples were taken at 30, 60 and 120 min after 1000 mg GPC intake. Moreover, all subjects repeated an identical protocol with placebo intake on another. Blood samples were analyzed for hormones and metabolites. Results: Plasma total choline levels significantly increased at 60 and 120 min after GPC intake. In response to a single dose of GPC, plasma GH secretion was enhanced significantly after 60min, whereas no significant change was observed for the placebo intake. Additionally, plasma free fatty acid (FFA) was raised at 120 min after GPC intake as compared with the placebo intake. Plasma acetoacetate and 3-hydroxybutyrate levels, which are the indexes of fat metabolism in the liver, both increased at 120 min after GPC intake, but no change was seen after placebo intake. GH, FFA, acetoacetate and 3-hydroxybutyrate alterations are greater at GPC intake compared with the placebo intake. No significant change in plasma glucose level was observed in either group. Conclusion: In response to an acute intake of GPC, GH secretion was enhanced in concomitant with plasma choline level. Furthermore, significant increase in FFA and concomitant increase in acetoacetate and 3-hydroxybutyrate were observed only after the choline intake. These findings suggest that a single dose of GPC intake may enhance GH secretion and fat metabolism in concomitant increase with choline level in young subjects. ### EFFECTS OF CAFFEINE SUPPLEMENTATION ON THE INFLAMMATORY RESPONSE INDUCED BY A 15 KM-RUN COMPETITION

TAULER, P.1, MONJO, M.1, MARTÍNEZ, S.2, BOSCH, E.2, MORENO, C.2, MARTÍNEZ, P.2, AGUILÓ, A.2

UNIVERSITY OF THE BALEARIC ISLANDS

Introduction Caffeine is commonly used by endurance athletes to improve performance. In addition to the ergogenic effects, caffeine could influence the inflammatory response induced by exercise because of its effects on catecholamines and because immune cells are one of the targets of caffeine. The aim of the study was to determine the effect of caffeine supplementation on the inflammatory response induced by physical activity in a competition. Methods A double-blinded study of supplementation with caffeine was performed. Athletes participating in the study ( $n=33$ ) completed a 15-Km run competition. Before competition athletes took 6 mg/kg body weight of caffeine (caffeine group,  $n=17$ ) or a placebo (placebo group,  $n=16$ ). Blood samples were taken before competition, immediately after finishing the competition and, also, two hours after finishing the competition. White blood cell counts, plasma AST and CK activities, as well as IL-6 and IL-10 levels were measured. Furthermore, IL-10 mRNA leukocyte expression was also measured by Real-time RT-PCR. Results The competition induced muscle damage, characterized by significant and similar increases in CK and AST activities in both placebo and caffeine groups. Caffeine supplementation induced higher increases in circulating total leukocyte count and neutrophils, with significant differences between groups after the short recovery period. However, caffeine ingestion did not influence lymphocyte response to the competition. Increases observed in IL-6 and IL-10 plasma levels after the competition were higher in the caffeine than in the placebo group. Total leukocyte IL-10 mRNA levels in response to the competition were similar in both groups, with significant increases two hours after finishing the competition. Discussion Changes observed in leukocyte counts were in agreement with previous results. It has been reported that caffeine supplementation induced higher increases in neutrophil number due to increased catecholamine levels in response to exercise and supplementation. IL-6 and IL-10 response to exercise was influenced by caffeine, with higher increases in the caffeine group. IL-6 has been proposed as the key factor in the response to exercise. In fact, IL-10 increases in response to IL-6. Because IL-6 and IL-10 have been classified as anti-inflammatory cytokines, caffeine supplementation seems to enhance the anti-inflammatory response to exercise. References Graham, T.E. Sports Med, 2001. 31(11): p. 785-807. Graham, T.E. and L.L. Spriet, J Appl Physiol, 1995. 78(3): p. 867-74. Pedersen, B.K., et al. Proc Nutr Soc, 2004. 63(2): p. 263-7.

### EFFECTS OF A COMBINED TREATMENT WITH CAFFEINE AND EXERCISE ON INSULIN RESISTANCE IN SKELETAL MUSCLES AND LIVER

MASATO, S., DAISUKE, S.

THE JIKEIKAI UNIVERSITY SCHOOL OF MEDICINE

PURPOSE: Keijzers reported that caffeine decreased insulin sensitivity by ~15% in healthy humans. Caffeine is known to promote lipolysis and enhance energy expenditure. Therefore, chronic consumption of caffeinated beverages may improve insulin resistance (IR). Moreover, it would be interesting to elucidate whether a combination of caffeine and exercise improves IR through reduction in visceral fat mass (VFM) and triglyceride (TG) content and increases glycogen (Gly) accumulation in the liver and skeletal muscles. The present study aimed to clarify the effects of caffeine intake and exercise and their combined effects on VFM and the contents of TG and Gly, known as

indicators of insulin resistance, in obese diabetic OLETF rats. **METHODS:** Twenty-four OLETF rats were divided into the following groups: sedentary (-Sed), exercise (-Ex), caffeine (-Caf), and a combination of exercise and caffeine group (-Ex & Caf). Each treatment was conducted in rats from 25 to 29 weeks of age. Rats in the -Caf and -Ex & Caf groups were fed rat chow containing 0.25% caffeine. Rats in the -Ex and -Ex & Caf groups were allowed to voluntarily run every day. Body weight (BW) and blood pressure were measured once every week. After completion of the 5-week treatment, blood samples were collected. Fasting blood glucose (FBG), insulin, leptin, and lipid concentrations were measured. HOMA-IR was also calculated. The liver, skeletal muscles, and VFM were weighed. The TG and Gly contents in the liver and quadriceps femoris were measured. **RESULTS AND DISCUSSION:** FBG and HOMA-IR remarkably improved in the case of rats in the -Ex and -Ex & Caf groups after the treatment. In particular, VFM tended to be lower in the -Ex & Caf group than in the -Ex group and the -Caf group. The liver TG and Gly contents were considerably higher in the -Sed group than in the other 3 groups. The results of the present study indicate that chronic consumption of caffeine improves IR in the liver and skeletal muscles, decreases TG content in the skeletal muscle and the liver, and increases Gly content in the quadriceps femoris. Interestingly, a combined treatment with caffeine and exercise considerably decreased TG content in the liver and increased Gly content in the quadriceps femoris; however, the TG content in the quadriceps femoris and the Gly content in the liver did not differ between the -Ex, -Caf, and -Ex & Caf groups. **CONCLUSION:** The results suggest that a combined treatment with caffeine and exercise is more efficacious than is single treatment with either caffeine or exercise for improving IR in the skeletal muscles and for reducing VFM and serum lipid concentrations.

### EFFECTS OF CAFFEINE SUPPLEMENTATION ON OXIDATIVE STRESS AND ENERGETIC METABOLISM IN A 15 KM-RUN COMPETITION

AGUILÓ, A.1, MARTÍNEZ, S.1, BUJOSA, G.2, SALVÀ, A.1, MARTÍNEZ, P.1, MORENO, C.1, TAULER, P.2

UNIVERSITY OF BALEARIC ISLANDS

**Introduction** Caffeine is an ergogenic aid commonly used by endurance athletes. It has been suggested that caffeine, as a consequence of ergogenic mechanisms, could increase oxidative stress induced by exercise. The aim of the study was to determine the effect of caffeine supplementation on energy metabolism parameters and on the oxidative stress induced by physical activity in a competition. **Methods** A double-blinded study of supplementation with caffeine was performed. Athletes participating in the study (n=33) completed a 15-Km run competition. Before competition, athletes took 6 mg/kg body weight of caffeine (caffeine group, n=17) or a placebo (placebo group, n=16). Blood samples were taken before competition, immediately after finishing the competition and, also, two hours after finishing the competition. Caffeine, glucose, free fatty acids and lactate levels were measured in plasma. Furthermore, oxidative stress markers (MDA and lipid hydroperoxides) as well as antioxidant (vitamin C and uric acid) levels were also determined in plasma. **Results** Plasma caffeine was detected only in the caffeine group after supplementation. Glucose and lactate plasma levels increased after the competition, with significant higher increases in the caffeine group than in the placebo one. However, no differences between groups were observed in plasma free fatty acids levels, which had been also increased after the competition. Oxidative stress markers increased after the competition. Lipid hydroperoxides increases were higher in the caffeine group than in the placebo one. MDA increases were non significantly higher in the caffeine group. Similar increases were observed in both groups after the competition in plasma vitamin C and uric acid levels. **Discussion** Results obtained in the present study confirm the paradoxical finding that caffeine supplementation induces higher increases in lactate levels in response to exercise. It has been suggested that this response could be induced by an effect of caffeine on lactate clearance. On the other hand, this study revealed a possible effect of caffeine increasing oxidative stress characterized by markers such as lipid hydroperoxides, with a significant difference between groups, and MDA, with a non significant difference between groups. **References** Graham, T.E. #### MATHEMATICAL MODEL FOR THE EFFECTS OF ACCELERATIONS AND DECELERATIONS DURING VARIABLE POWER CYCLING TIME TRIAL PERFORMANCE

WELLS, M., ATKINSON, G., MARWOOD, S.

LIVERPOOL HOPE UNIVERSITY.

**Mathematical model for the effects of accelerations and decelerations during variable power cycling time trial performance** M. Wells.1, G. Atkinson.2 and S. Marwood.1 1:Faculty of Science and Social Sciences (Liverpool Hope University, Liverpool) 2:R.I.S.E.S (Liverpool John Moores University, Liverpool) **Introduction** Previous researchers have modelled the impact of stochastic versus constant power output during a cycling time trial (TT) and demonstrated an increase in the time to complete a flat, windless course when power output fluctuates (Swain, 1997; Atkinson et al., 2007). These researchers modelled relatively long variation periods (5 km and greater) and considered the effects of acceleration and deceleration to be negligible. We aimed to examine the effects of more frequent variations in power output and include acceleration/deceleration components in our model of cycling. **Methods** We used a previously validated equation of motion (Martin et al., 2006) and forward integration (2 Hz) to account for the effects of acceleration and deceleration. Assuming a starting speed of 1m.s<sup>-1</sup>, the time to complete a flat, windless 40-km TT was calculated utilising a hypothetical rider with a mass of 70 kg, bicycle mass of 10 kg and a drag area of 0.2914 m<sup>2</sup>. A range of mean power outputs of 200 – 600 W (50 W increments) were considered and within-race power was systematically varied by  $\pm 0$ ,  $\pm 5$ ,  $\pm 10$  or  $\pm 15\%$  for periods of variation of 1.25, 2.5, 5, 10, 20 and 40 km; all possible combinations were modelled. **Results** Increasing the amplitude of variation and period of power variation caused independent increases in completion time. For a mean power output of 400 W, there was an increase in completion time of 0.02, 0.09 and 0.23% when the amplitude of variation during 5-km periods was increased from 0% (constant state) to 5, 10 and 15%, respectively. When the period of variation was decreased from 40 km (constant state) to 20, 10, 5, 2.5 and 1.25 km with 10% amplitude of variation, there was an increase in completion time of 0.10, 0.10, 0.09, 0.09 and 0.07% respectively. This negative impact of increasing amplitude and period of variation was attenuated as mean power output increased. **Discussion** The present data, which controlled for the influences of acceleration and deceleration, demonstrate that constant, versus variable, power output produces the shortest TT duration when external conditions are constant. However, the effects of varying power output decrease as the amplitude and period of variation are reduced. Though attenuated at higher power outputs these effects are reasonably consistent, suggesting that regardless of ability cyclists should attempt to maintain the

highest possible constant power output. References Atkinson G, Peacock O, Passfield L. (2007). *Journal of Sports Science*, 25, 1001-1009. Martin J, Gardner A, Barras M, Martin D. (2006). *Med Sci Sports Exerc*, 38, 592-597. Swain D. (1997). *Med Sci Sports Exerc*, 29, 1104-1108.

### **NORMALIZATION OF KNEE EXTENSOR SURFACE EMG TO JOINT ANGLE**

EARP, J.

EDITH COWAN UNIVERSITY

**Introduction** Surface electromyography (sEMG) normalization is the process of comparing a referenced contraction to those collected within or between testing sessions increasing reliability when comparing measurements between different trials or days. sEMG signals are often normalized to a given force or velocity, however, joint angle is rarely taken into account. Maximal muscle activity changes with joint angle due to a range of factors and it is important to perform normalization when sEMG is measured over a large (range of motion) ROM. **Methods** Sixteen healthy physically active men (n=8) and women (n=8) performed large ROM (110°-0°) isokinetic knee extensions at 30°·s<sup>-1</sup>, during which joint position and sEMG of the vastus lateralis (VL), medialis (VM) and rectus femoris (RF) were recorded and analyzed using a custom LabView program. sEMG signals (2000 Hz) were full-wave rectified, filtered using a Butterworth 6th-order 10-500Hz bandpass filter, and smoothed using a 2nd-order 6-Hz linear envelope. Treated signals were then fitted to one of four joint angle-sEMG models: linear (Lin) or 2nd (2P), 3rd (3P) or 4th (4P) order polynomials. The mean-squared error (MSE), sEMG activation range and sEMG values at 0°, 45°, 90° and 110° knee flexion were compared between normalization models. Ten subjects performed an additional five isotonic knee extensions using a range of loads. sEMG was then normalized using the four joint angle-sEMG models as well as to the peak RMS (2.5s window). Repeated measures ANOVAs with Bonferroni post hoc tests were used to determine differences between the four normalization methods ( $p < 0.05$ ). Results Maximal muscle activation varied significantly between joint angles for the RF (25%), VM (16%) and VL (12%). The average MSE decreased for all recorded knee flexors as the complexity of the fitted curve increased (Lin<2P<3P<4P), but increases were not always statistically significant. However, differences in signal variance and MSE were observed between Lin and 2P for VL and 2P and 3P for VM and RF. Differences between normalization models were greatest at 0° and 110° for the RF and VM muscles. sEMG signals corrected for knee angle during isotonic trials had significantly greater peak and average values than when normalized using the peak RMS. **Conclusions** Maximal sEMG values were influenced by joint angle. Also, signals normalized to knee angle were significantly different to those normalized using peak RMS, supporting the efficacy of a knee angle-dependent normalization model. All normalization models appeared to provide valid corrections, but using 2P when correcting for VL and 3P when correcting for RF and VM better match the true signals than less complex processing methods.

### **3D ACCELEROMETER AS A TOOL FOR SPEED DEVELOPMENT IN SPRINT**

DJORDJEVIĆ, S.1,2, MEGLIČ, A.1

UNIVERSITY OF PRIMORSKA (2), KOPER, SLOVENIA, TMG-BMC LTD. (1) LJUBLJANA, SLOVENIA

**Introduction** Sprint running is a very dynamic sporting activity where intensive events and impact forces occur in very short time intervals. Inefficient and uneconomical running results in lower maximal speeds and increase of musculoskeletal injuries. However it is generally accepted that sprint performance can improve considerably with training. Because of the limitation and subjectivity of our senses different tracking systems are used. **Methods** There are currently several fundamental tracking technologies, such as mechanical, optical, acoustic and inertial tracking. Among these, inertial tracking technology has attracted considerable interest since accelerometer technology has advanced significantly, making these devices small, light and portable enough to be placed on the athlete body. We used a triaxial accelerometer LIS331HH (ST Microelectronics, USA), that returns a real valued estimate of acceleration along the x, y and z axes. The accelerometer is capable of sensing accelerations up to 24 g. The sensor unit (HSS1, TMG-BMC, Ltd., Slovenia) included a triaxial accelerometer, triaxial gyroscope, microcontroller and a wireless module. Whole unit weighted 25 grams. Data were sampled at 1 kHz, stored in internal memory or transmitted wirelessly to a computer, allowing for measurements to be taken on a track in real competitive or workout situation. A group of sprinters (six females and two males) running 40 m flying were monitored with the sensor unit attached to the lumbar spine (L4-L5 position). Running speed was approximately 10 m/s for males and 9.4 m/s for females. During this near to constant velocity phase athletes made 17-18 steps. Since human running is a periodic system in dynamic equilibrium (Hamill & al. 1995) a special algorithm was designed to detect individual steps in accelerometer signal. Several identification strategies are possible but we obtained the most robust results with localizing maxima and minima within a fixed interval. Because the individual steps are not equidistant, dynamic time warping was used. Thus aligned signals are suitable for further statistical analysis or for mapping characteristics of the reference step to others. **Results** Different kind of asymmetrical movement was found at nearly all sprinters. The asymmetry could be as large as 20 %. **Discussion** Described method allows us to easily detect the errors in the running technique. The obtained results also demonstrate that fatigue influences the signal pattern. We demonstrate that the use of 3D accelerometer and data analysis software can help us optimize the training, increase running efficiency and reduce the risk of injuries. ### **CHOOSING THE RIGHT BODY POSITION FOR ASSESSING TRUNK FLEXORS AND EXTENSORS TORQUE OUTPUT**

SZPALA A.1, RUTKOWSKA-KUCHARSKA A.1, DRAPALA J.2, BRZOSTOWSKI K.2

1. UNIVERSITY SCHOOL OF PHYSICAL EDUCATION IN WROCLAW, 2. WROCLAW UNIVERSITY OF TECHNOLOGY

**Introduction** Sitting position is generally adopted when measuring torques produced by flexors and extensors of the trunk (Wit A., 1992). Results of such measurements are influenced by the strength of both abdominal muscles and flexors of the hip joint. In order to assess the effect of exercises used to strengthen the abdominal muscles it was necessary to find such a measuring position which engaged mainly the abdominal muscles. The objective of the study was an assessment of EMG activity of abdominal and spinal muscles during the measurements of muscle torques in the sitting position, as well as in the lying position. **Methods** Thirteen female students of the University School of Physical Education in Wrocław participated in the study. The methods of measuring muscle torques and surface electromyography (sEMG) were used under static conditions. The torques were measured on a multifunctional chair in the lying and sitting position (Szpala et al., 2010). The surface EMG electrodes were placed on the right and left hand side of m. rectus abdominis (RA) and m. erector spinae (ES) (Clark et al., 2003). Signals from both muscles were sampled at 1000 Hz. **Results** The maximal torques of trunk flexors in the sitting position and in the lying position were similar: 130.6±31.7 Nm and 129.8±37.9 Nm, respectively. By contrast, the torque of trunk extensors was significantly larger when the measurement was carried out in the sitting position (228.1±76.4 Nm) as compared with the lying position (148.8±25.3 Nm). The ratio of the maximal torques of flexors and extensors of the trunk in the examined

women was 0.572 in the sitting position and 0.872 in the lying position. Both RA and ES showed higher EMG activity in the lying position than in the sitting position. Discussion The higher EMG activity of the RA muscle in the lying position at the same values of the trunk flexors torque in both positions may suggest that in the sitting position flexors of the hip joint are more engaged than abdominal muscles. That is why, in order to assess the effects of abdominal muscles training, measurements of the trunk flexors torque should be performed in the lying position (Szpala et al., 2011) References Wit A. ### **"DGPSANA": ADVANCED RTK-GNSS DATA ANALYSIS IN ALPINE SKIING DAILY TRAINING**

SUPEJ, M.

UNIVERSITY OF LJUBLJANA, FACULTY OF SPORT

"DGPSana": ADVANCED RTK-GNSS DATA ANALYSIS IN ALPINE SKIING DAILY TRAINING Supej, M. Dept. of Biomechanics, Faculty of Sport, University of Ljubljana, Ljubljana, Slovenia Introduction It has been shown that among the fastest alpine skiers time differences in shorter sections along the course can vary by 10% (Supej & Cernigoj, 2006). Despite that, the technique and/or tactical differences are often too minute to observe with the naked eye. Furthermore, established photocells provide only limited time information. The aim of the present study was to demonstrate the usefulness of a high-end Global Navigation Satellite System (GNSS) in daily alpine ski training, by using custom-built analysing routines. Methods Two elite skiers participated in the study, each performing four runs through a 29-gate long slalom course. The runs were simultaneously recorded with a camcorder and an RTK GNSS Leica GX1230 GG (Leica Geosystems AG, Heerbrugg, Switzerland). The GNSS surveys positions with 1–2 cm accuracy at a 20 Hz sampling rate. Skis and centre-of-mass trajectories were calculated using the methodology described by Supej et al. (2008). A "DGPSana" custom-built analysis system was designed in Matlab R2007a (Mathworks Inc., Natick, MA) in order to calculate and analyse the mechanical parameters simultaneously with recorded video clips. Results DGPSana enabled detailed analysis of the recorded data after the training session. The gate-to-gate lag times showed differences between the runs ranging up to 0.1 s (10%). For each run, sections of different performance levels were identified using cumulative gate-to-gate lag times. In addition, the *diffle\_mech* (Supej 2008) values showed the exact location where the skier's energy behaviour was good or poor. The centre-of-mass velocities were used to examine the consequences of energy behaviour. Finally, the comparison of trajectories demonstrated the differences in skied lines. Discussion The results demonstrated the high usability of the RTK GNSS data for daily training purposes, when they were analysed using DGPSana. The methodology enables 1) quantifying skiers' mistakes and 2) identifying differences that cannot be observed by a computer-aided video analysis. Finally, RTK GNSS with DGPSana provides coaches a daily training tool to judge technique and tactics differences more precisely. References Supej, M., Cernigoj, M. (2006). ### **FLEXO-ROTATION TRUNK TEST VALIDITY FOR MEASURING ABDOMINAL MUSCLE FATIGUE**

VERA-GARCIA, F.J., PECO-GONZÁLEZ, N., BROTONS-GIL, E., GARCÍA-VAQUERO, M.P.

MIGUEL HERNANDEZ UNIVERSITY OF ELCHE

Introduction The assessment of trunk muscle fatigue is a fundamental component of a physical fitness appraisal. Sagittal trunk extension and flexion tests (Coorevits et al., 2008; Knudson and Johnston, 1995) are generally used for measuring the back and abdominal muscle endurance. However, trunk endurance tests involving rotation or side bending are lacking. A flexo-rotation trunk (FRT) field test was developed to assess abdominal endurance simultaneously on a large number of people. The aim of this study was to evaluate the validity of the FRT test using surface electromyography (EMG). Methods Twenty-seven healthy subjects executed the FRT test. In this test participants performed the maximum number of cross-crunches in 90 s. Each repetition started in supine position with knee flexion at 90°, straight arms and hands overlapped over the pubis. Then, subjects curled up and twisted the trunk in order to touch their partner's fist placed on the lateral of his/her left knee. Subjects alternated left and right trunk twist. EMG was bilaterally recorded from rectus abdominis (RA), internal oblique (IO) and rectus femoris (RF), and the hip motion was measured using an electrogoniometer. The mean power frequency of the raw EMG (MPF) was calculated to evaluate muscle fatigue. In addition, in order to explore the role of the muscles in the FRT test, the raw EMG was rectified, averaged, and normalized to maximal voluntary isometric contraction (% MVC). Results At the beginning of the FRT test, the mean levels of RA activation (about 30% MVC) were higher ( $p < 0.05$ ) than those of IO (about 20% MVC) and RF (5-10% MVC), and the mean levels of IO activation were higher than those of RF ( $p < 0.05$ ). During the FRT test a significant reduction of the MPF was observed for the abdominal muscles. The percentage of MPF reduction was higher ( $p < 0.001$ ) for RA (about 45%) than for IO (about 25%) and RF (about 10%). In addition, the MPF reduction was higher for IO than for RF ( $p < 0.01$ ). The goniometric results showed a small mean hip flexion of 7.9° at the beginning of the test, which increased up to 14.3° at the end ( $p < 0.001$ ). Discussion Despite the hip motion observed during the test, the EMG analysis in the amplitude domain showed that the abdominal muscles were the prime movers, especially RA. The higher muscle activation of RA and IO resulted in greater MPF reduction, and consequently in higher muscle fatigue (Coorevits et al., 2008). These findings support the validity of the FRT test for measuring abdominal muscle fatigue in flexo-rotation trunk motions. References Coorevits P, Danneels L, Cambier D, Ramon H, Vanderstraeten G. (2008). J Electromyogr Kinesiol, 18(6), 997-1005. Knudson D, Johnston D. (1995). J Strength Cond Res, 9(3), 165-169.

### **FACTORS ASSOCIATED WITH JOINT RANGE OF MOTION CHANGES FOLLOWING A STATIC STRETCH SESSION**

COLLINS, M.1,2,3, MILLER, C.J.1, BROWN, J.C.1, SCHWELLNUS, M.P.1,3

1: EXERCISE SCIENCE AND SPORTS MEDICINE, UNIVERSITY OF CAPE TOWN (UCT), CAPE TOWN, SOUTH AFRICA, 2: MEDICAL RESEARCH COUNCIL, CAPE TOWN, SOUTH AFRICA, 3: IOC RESEARCH CENTRE, UCT, CAPE TOWN, SOUTH AFR

Introduction Static stretching is commonly performed on the assumption that it increases joint ROM. Observations from our laboratory indicate that there is a large inter-individual variance in the response to static stretching with some individuals showing a reduction in

ROM. The aim of this study was to investigate the factors that are associated with a change in ROM in response to a static stretch session. Methods Participants were 163 apparently healthy, physically active, non-obese and between 18-50 years. Consenting participants were requested not to participate in any unaccustomed physical activity, stretch or use medication, shown to affect ROM, in the 24 hours prior to testing. Questionnaires and a single straight leg raise (SLR) test on both legs was completed by all participants. One leg, randomly chosen as the intervention leg, was subjected to an acute static stretch session (SSS) (3 repetitions of 30 second stretching) with the other leg acting as an internal control. This was followed by a repeat SLR test on the intervention and control legs. End ROM was determined using EMG techniques. Flexibility and sport training, stretching, anthropometric variables, age and pre-SLR measurements were included as variables in various statistical analyses to determine independent factors associated with change in ROM measurements in response to a static stretch session. Results There were no significant differences between the pre-SLR measurements of the intervention and control legs. The post- and change in SLR measurements of the intervention leg were significantly greater than the control leg ( $P < 0.001$ ). The average change in SLR measurements of the intervention leg was  $7.2 \pm 7.0^\circ$ , (range:  $-16.5^\circ$  -  $30.0^\circ$ ). Of the investigated independent factors, only pre-SLR ( $P = 0.005$ ) and post-exercise stretching ( $P = 0.031$ ) were associated with the change in SLR measurements in response to a SSS and together, accounted for 10% of the variance in the change. Larger pre-SLR measurements were associated with a smaller decrease in the change of SLR ( $r = 0.016$ ) following a SSS. Conclusion There is a variable response of joint ROM to a SSS, with a significant portion of the participants showing a reduction in ROM. Pre-SLR measurements were the most important factor that determined changes in ROM following a SSS.

## EFFECT OF UPPER LEG CONTACT TO DYNAMOMETERS' BAR WHILE PULLING ON BACK AND LIFT TEST RESULTS

ASLAN, C.

ANKARA UNIVERSITY

Introduction Testing and measurement is one of the important component of performance assessment but some details that underestimated may directly affect test result. The purpose of this study is determined effect of non suitable gripping technical in back and lift dynamometer, like bar may contact with legs, on test results. Methods Back & Lift Dynamometer Test procedure can be defined as follows according to literature (Tamer, 2000); subjects stand upright on the base of the dynamometer with their feet shoulder width apart. Arms hang straight down to hold the center of the bar with both hands; adjust the chain so that the knees are bent at approximately 110 degrees. In this position, the back should be bent slightly forward at the hips, head should be held upright, and should look straight ahead. Then without bending back, pull as hard as possible on the chain and try to straighten legs, keeping arms straight. In this study; 9 female and 23 male ( $n = 32$ ) athlete voluntarily participate for this research. Participants' leg strength was measured by Takei (Japan) back and lifts dynamometer. Strength dynamometers have been known as valid and reliable devices in order to estimate strength for years (Bookwalter, 1950, Ozer, 2001, Muratlı et al 2007). Participant performed 4 pulling trials, 2 of them without legs contact (WLG) and other 2 trials legs contact with bar (LC). Best performances are recorded for two types of trials. Obtained data were analyzed by SPSS (ver. 16). Wilcoxon Two-Related-Samples test was used to compare groups and  $\alpha$  was set as 0, 05. Results Mean age of female athletes were found  $21.44 \pm 1.24$  years, weight as found  $57.56 \pm 8.09$  kg, height was found  $166.89 \pm 4.01$  cm, LG  $106.44 \pm 20.86$  kg and WLG  $69.44 \pm 15.26$  kg. Male groups average values was found respectively; for age  $22.22 \pm 1.31$  years, body weight  $71.96 \pm 6.62$  kg, height  $176.83 \pm 4.95$  cm, LG  $207.24 \pm 55.40$  kilogram and leg strength without bar contact legs  $139.14 \pm 119.67$  kilogram. Both of groups has statistically significant differences between with and without legs contact to bar (For female  $p = 0.008$ , for male  $p = 0.000$ ;  $p < 0.05$ ). Discussion During the pulling phase, if the legs contact with bar, this case causes a sharply increase of leg strength values for female in the rate of 53,62 % and 49,92 % for male athletes compared with non-contact pulling. So while dynamometers test realized, "leg contact case" should be considered by researcher for objective measurement. References Tamer, K. ## ESTIMATION OF RELATIVE LOAD FROM MEAN VELOCITY IN THE FULL SQUAT EXERCISE

SÁNCHEZ-MEDINA, L., GARCÍA-PALLARÉS, J., PÉREZ, C.E., FERNANDES, J., GONZÁLEZ-BADILLO, J.J.

PABLO DE OLAVIDE UNIVERSITY, SEVILLE

ESTIMATION OF RELATIVE LOAD FROM MEAN VELOCITY IN THE FULL SQUAT EXERCISE. Sánchez-Medina, L.I, García-Pallarés J.2, Pérez CE.2, Fernandes J.3, González-Badillo JJ.1 1: UPO (Seville, Spain), 2: UMO (Murcia, Spain), 3: FADEUP (Porto, Portugal) Introduction Despite being generally considered a fundamental multi-joint exercise in strength and conditioning programs for sports that require high levels of strength and power, limited published research has analyzed the kinematics of the full squat (Escamilla, 2001). Since it has recently been shown that movement velocity can be used to adequately estimate loading intensity (%RM) in the bench press (González-Badillo and Sánchez-Medina, 2010), this study examined the possibility of using mean velocity (Sánchez-Medina et al., 2010) to estimate relative load in the full squat (SQ). Methods Ninety strength-trained male athletes [mean(SD): age 23.5(5.1) yr, height 177.4(7.7) cm, body weight 74.6(10.1) kg, body fat 12.0(4.7)%, capable of at least full squatting with an external load equivalent to their own body weight, performed a strength test with increasing loads up to the 1RM for the individual determination of the load-velocity profile. Subjects were required to descend until the top of the thighs got below the horizontal plane, the posterior thighs and shanks making contact with each other. The concentric phase was always performed at maximal velocity. A linear velocity transducer sampling at 1,000 Hz (T-Force System, Ergotech, Spain) was attached to a Smith machine and used for all mechanical measurements. Velocity-load relationships were studied by fitting 2nd order polynomials to data. Results A very close relationship between mean propulsive velocity (MPV) and load (%RM) was observed ( $R^2 = 0.96$ ). Mean velocity attained with 1RM (V1RM) was  $0.34 \pm 0.05$  m/s. Prediction equations to estimate load from MPV and mean velocity (MV) were obtained:  $\%RM = -2.185 MPV^2 - 61.53 MPV + 122.5$ ,  $R^2 = 0.96$ ,  $SEE = 5.5\%RM$  for MPV; and  $\%RM = -8.89 MV^2 - 58.55 MV + 122.4$ ,  $R^2 = 0.94$ ,  $SEE = 6.2\%RM$  for MV. Discussion The results of this study confirm an inextricable relationship between relative load and mean velocity in the SQ; i.e. each %RM has its own MV or MPV value. This finding makes it possible to: 1) evaluate strength without the need to perform a 1RM test, or test of maximum number of repetitions to failure (XRM); 2) determine the %RM that is being used as soon as the first repetition with any given load is performed; and 3) prescribe and monitor training load according to velocity, instead of percentages of 1RM or XRM. It is recommended that the provided prediction equations are not used with velocities higher than 1.20 m/s since there exists considerable velocity variability when the SQ is performed with light loads ( $< 50\%RM$ ) due to the inherent characteristics of this exercise. **VALIDATION OF E-TEXTILE STRAIN SENSOR TECHNOLOGY FOR MEASURING KNEE FLEXION DURING KICKING**

BLANCHONETTE, I.1, HELMER, R.1, BALL, K.2, PHILLIPS, E.2, FARROW, D.2.3, FAROUIL, A.1

CSIRO

**Introduction** Accurate and reliable measurement of skills and skill development is typically limited to a laboratory setting or simplified performance environment. Electronic textiles with sensors, such as strain sensors, are enabling measurement in a way that allows motion capture and real-time or rapid-time feedback stimuli in diverse training and competition environments. The 'e-textile' technology affords numerous opportunities for monitoring and training in the performance environment if such devices can be proven to be suitably accurate and reliable (Helmer et al., 2010). The purpose of this study was to compare electronic textile 'e-leggings' and 3D motion capture measurement systems to determine knee angle during kicking. **Methods** A pair of e-leggings was prepared by mounting textile strain sensors across the left and right knees on a pair of leggings commonly worn in sports training. A custom wireless electronic unit (40x40x12mm, located on the waist), sampling at 250Hz, streamed kinematic information from the e-leggings to a computer in real-time. The ability of the e-leggings to reliably monitor leg motion was assessed for a set of exercises involving running and kicking (soccer, rugby and Australian football kicks) in a motion capture laboratory. Three dimensional kinematic data was collected using a Optotrak Certus system (Northern Digital Inc., Waterloo, Canada, root mean square error of 0.1mm in 2D and 0.15mm 3D) operating at 100Hz. Marker clusters were placed on the thigh and shank with the knee joint axis located using a digital probe and functional tasks. Knee angle data from participants were calculated using each system to ascertain whether significant differences exist in knee angle data between the two measurement systems. **Results** Preliminary results during a range of lower limb tasks including kicking suggested the e-leggings were shown to perform very well when compared to the Optotrak Certus system, ( $R^2$  range 0.91 - 0.98), and was consistent with previous studies with similar garments on other limbs (Helmer et al. 2008). **Discussion** The e-leggings were found to be a valid tool for the real-time measurement and interpretation of key lower limb angles when running and kicking footballs. The freedom of movement allowed by the garment based system will allow running and kicking performance to be measured and biofeedback provided within the natural performance environment. **References** Helmer R, Farrow D, Lucas S, Higgerson G, Blanchonette I. **A PROTOCOL FOR MONITORING SOFT TISSUE MOTION UNDER COMPRESSION GARMENTS.**

MILLS, C.

UNIVERSITY OF PORTSMOUTH

**Introduction** Establishing a valid and reliable protocol for monitoring soft tissue motion under compression garments is important before the effects of these garments on performance can be assessed. A protocol should aim to discriminate soft tissue motion between varying levels of compression, accurately assess motion under the garment and demonstrate acceptable reliability. **Methods** Within this study, the participant performed six 40 cm drop landings in no, medium and high compression garments onto a force platform. Two cameras (1000 Hz) collected video footage of the dynamic trials. Using a purpose built template ten markers were placed in pairs on the thigh. All markers were taped on the skin during no compression conditions and five markers (one from each pair) were taped on the skin (under the garment) and five on the surface of the garment during compression conditions. Maximum change in resultant separation distance for each marker pair was calculated. Typical errors (TEs) were calculated to assess variance in the displacement of markers placed under and over the garment. During static trials thirty five markers were applied, removed and re-applied to the participant's thigh. Six additional markers were placed on landmarks to identify the pelvis and thigh centre of gravity (CoG). Eight cameras tracked the markers as the participant stood in the anatomical position for 3 s. Distances from outer markers to thigh CoG and relative marker separations were calculated. **Results** Force data showed similar landings were performed during each trial. T-tests identified no difference in maximum marker separation between none and medium compression. However, reductions in marker separation from none to high and medium to high compression ( $p=0.00$ ) were detected. TEs in the displacement of markers placed under and over the garment were 0.1mm in compression conditions. No differences ( $p=0.87$ ) in marker positions or in marker separation ( $p=0.93$ ) after marker re-application were found. **Discussion** Significant reductions in marker separation distances between none and high; and medium and high compression suggest that the protocol was sufficiently sensitive to detect reductions in soft tissue motion. With typical thigh soft tissue displacements during drop landings of ~32 mm (Pain & Challis, 2006), the variability in the displacement of markers placed under and over the garment equates to <0.5% in the compression conditions. Static trials showed marker re-application was repeatable to within 3 mm. With a participant thigh length (ASIS to patella) of 430 mm the marker array was placed within 1 % after re-application. In conclusion, this protocol is a valid and reliable method for monitoring thigh soft tissue motion under compression garments during drop landings. **References** Pain, M. & Challis, J. (2006). **STUDY REGARDING TORQUE MEASUREMENTS-ARE THE DIFFERENCES IN MUSCLE MEASUREMENTS CAUSED BY SEX DIFFERENCE QUALITATIVE OR QUANTITATIVE?-**

KITA, T.1, YAMAMOTO, T.2, YOSHIHARA, S.3, MIURA, M.4, MIURA, K.4, AKITA, K.4, KATOH, Z.5, TAMURA, M.6, REE KYOUG, O.K.7, CHUN JI, H.8

1:TEIKYO UNIVERSITY OF SCIENCE(JAPAN), 2:MUSASHINO ART UNIV., 3:ST.MARIANNA UNIV., 4:TOYO UNIV., 5:AICHI MIZUHO COLLEGE, 6:MEIJI UNIV., 7:EWHA WOMEN'S UNIV.(KOREA), 8:KAWASAKI UNIV. OF MEDICAL WELFARE

**Introduction:** In this study, we conducted new body-trunk measurements adding to hip-joint muscle strength, which was measured in our preceding study, to review the relevance among the data. **Method:** The following 10 items were measured: 1. height, 2. body weight, 3. adductor muscle torque in the hip joint, 4. abductor muscle torque in the hip joint, 5. right upper thigh, 6. right lower thigh, 7. left upper thigh, 8. left lower thigh, 9. abdominal muscle in the sitting position, and 10. back muscle in the sitting position. **Subjects:** 24 female and 13 male. **Time of measurement:** December 2010 **Results:** Analyses of correlation by sex showed that the relevance among the measured values that have statistically significant correlations was different between men and women. We conducted correlation analyses using all the acquired data through which statistically significant correlations were extracted among all the items. Then the extracted correlations were plotted on scatter diagrams by coding colors by sex. Individual differences in the trunk muscles were minimal, and the men's and women's data each showed scattered distributions according to the individual's muscle differences. The hip-joint muscle data, however, showed no distinctive gap between men and women, and some data among the two even clearly overlapped in many areas. The analyses of variation on the data of men's hip-joint muscles showed that for the hip flexor, the left-side muscles are significantly stronger than the right side; and for the extensor, the right side is significantly stronger than the left. The same results were shown in our previous study.

Regarding the body trunk muscles, a statistically significant correlation was seen between the abdominal muscles and the back muscles, and this result was common between men and women ( $r = 0.94$ ,  $p < 0.01$  in men;  $r = 0.60$ ,  $p < 0.05$  in women). Also according to variance analyses, the back muscles were stronger than the abdominal muscles in both men and women; however, the differences were significantly greater in men than women. Discussion/Conclusion: In this study, the plotted diagrams on correlations among the data regarding the hip-joint muscles, which were coded with different colors by sex, showed stronger correlations among data, with some parts specifically overlapping. This means that some of the male and female subjects showed extremely similar trends in physical traits and relevance among each of the measured items of the hip-joint muscles. It is an interesting question as to whether this similarity can be regarded as a mere accidental coincidence among stochastic variations in the (qualitatively) different populations, or whether the similarity can be regarded as evidence of the existence of individuals in the intermediate zone that link the higher layer (mainly males) and the lower layer (mainly females) in an (uninterrupted) population. It is at the same time a subject for future investigation.
