## Congress President

- Tim Cable (GBR)

## ECSS Executive Board

- Hans Hoppeler (CH), *President*
- Albert Gollhofer (GER), *Past President*
- Sigmund Loland (NOR), *President Elect*
- Romain Meesusen (BEL), *Exchanges and Affiliations*
- Marco Narici (GBR), *Finances and Partners*
- Gisela Sjøgaard, (DEN), *Journal and Media Relations*

## ECSS Scientific Board

- Anton Wagenmakers (GBR), *Chair*
- Peter Bärtsch (GER)
- Jan Cabri (PRT)
- Flemming Dela (DNK)
- Paavo Komi (FIN)
- Erich Müller (AUT)
- Gertrud Pfister (DNK)

## ECSS Scientific Committee

- Natalia Balague (ESP)
- Daniela Caporossi (ITA)
- Nenad Dikic (SR)
- Joan Duda (GBR)
- Michael Grey (GBR)
- Daniel Green (GBR)
- Steve Harridge (GBR)
- Werner Helsen (BEL)
- Asker Jeukendrup (GBR)
- Luc van Loon (NED)
- Mike McNamee (GBR)
- Hermann Schwameder (GER)
- Mark Williams (GBR)

## Local Scientific Committee

- Greg Atkinson (GBR)
- Simon Bennett (GBR)
- Jatin Burniston (GBR)
- Tim Cable (GBR)
- Graeme Close (GBR)
- Barry Drust (GBR)
- Geena Ellison (GBR)
- Keith George (GBR)
- Danny Green (GBR)
- Adrian Lees (GBR)
- Mark Nesti (GBR)
- Dave Richardson (GBR)
- Gareth Stratton (GBR)
- Greg Whyte (GBR)
- Mark Williams (GBR)

### **Additional reviewers**

- Gabor Barton (GBR)
- Alan Batterham (GBR)
- Karen Birch (GBR)
- Ellen Dawson (GBR)
- John Dickinson (GBR)
- Dominic Doran (GBR)
- Ben Edwards (GBR)
- Martin Eubank (GBR)
- Stuart Fairclough (GBR)
- Paul Ford (GBR)
- Warren Gregson (GBR)
- Dave Harriss (GBR)
- Malcolm Hawken (GBR)
- Spencer Hayes (GBR)
- Nicky Hopkins (GBR)
- Zoe Knowles (GBR)
- Helen Jones (GBR)
- Mark Lake (GBR)
- Martin Littlewood (GBR)
- James Morton (GBR)
- Becky Murphy (GBR)
- Colin Robertson (GBR)
- Mark Robinson (GBR)
- Clare Stapleton (GBR)
- Mark Scott (GBR)
- Rob Shave (GBR)
- Dick Thijssen (GBR)
- Vicky Tolfrey (GBR)
- Jos Vanrenterghem (GBR)
- Karen Williams (GBR)

### **Organizing Committee**

- Jatin Burniston (GBR)
- Tim Cable (GBR)
- Anne Doherty (GBR)
- Sheila Geary (GBR)
- Keith George (GBR)
- Denise Glinister (GBR)
- Adrian Lees (GBR)
- Rachel Martyn (GBR)
- Zoe Miveld (GBR)
- Dave Richardson (GBR)
- Dave Rutt (GBR)
- Jane Townend (GBR)
- Greg Whyte (GBR)
  
- Thomas Delaveaux (GER)
- Elias Tsolakidis (GRE)
- Tobias Vogt (GER)
- Sarah Köster (GER)

# Welcome

---

We are delighted, on behalf of the European College of Sport Science and the Research Institute of Sport and Exercise Sciences (RISES) at Liverpool John Moores University, to welcome you to Liverpool for the 16th Annual Congress of the ECSS.

The Congress theme of “New Horizons from a World Heritage City” provides a platform for our internationally renowned Plenary and Invited Speakers to stimulate and promote new research directions in our core Sport Science disciplines. These sessions will be supported, as ever, by the Young Investigator Awards of which we have the largest ever submission of 211 presenters. We are also particularly proud to have attracted 1756 abstracts, which will bring energy, academic rigour and debate to the 74 oral sessions and 120 poster sessions across the 4 days of the Congress. This volume of submitted work reflects the importance of our discipline to the societies in which we live and to the continued development of the College. A particular highlight of the Congress this year will be the presentation of the Tom Reilly Memorial Lecture, by Professor George Brooks, entitled “Three Decades of Research on Lactate Metabolism; A conversation with Tom Reilly”. The programme has been designed to inspire debate and academic exchange and we trust that you will leave the Congress sufficiently challenged and energised to build new horizons for the future.

We are very excited to welcome you to our City of Liverpool, which is well known for its friendliness and fun. We trust that you will take time to network and socialise with friends and colleagues in the many restaurants and bars in the Albert Dock and City Centre that are all within walking distance of the Conference. In addition, we hope you will have time to explore the many cultural opportunities that range from world famous art galleries, to gothic architecture, to theatre, musical and sporting heritage.

On behalf of RISES and the ECSS we thank you for travelling to Liverpool and your continued commitment to ECSS. We trust that you will have a fruitful and pleasant visit to the North West of England.

Best wishes

Tim Cable

*Congress President*

<b>ORGANISATION.....</b>	<b>3</b>
<b>WELCOME.....</b>	<b>5</b>
<b>TABLE OF CONTENTS .....</b>	<b>7</b>
<b>WEDNESDAY, JULY 6TH, 2011 .....</b>	<b>15</b>
<b>15:00 - 16:30.....</b>	<b>15</b>
IS-PM01 Sports Nutrition Symposium (sponsored by GSK) .....	15
IS-PM02 Eccentric Training and Exercise in Sport.....	16
IS-PM03 Cardiovascular Imaging in Sport Science: What does the future hold?.....	17
OP-BN05 Fatigue.....	18
OP-PM04 Health.....	20
OP-PM08 VO2max and O2 Kinetics.....	22
OP-PM12 Training and Testing: Team Sports .....	25
OP-PM52 Science and Soccer.....	26
OP-SH01 Sociology and Philosophy.....	28
OP-SH02 Sport Psychology 1 .....	30
<b>17:00 - 18:15.....</b>	<b>32</b>
PS-PL01 NEW HORIZONS: For the Challenge of Reducing Sedentary Activity in Humans.....	32
<b>THURSDAY, JULY 7TH, 2011 .....</b>	<b>34</b>
<b>08:30 - 10:00 .....</b>	<b>34</b>
IS-PM04 The Biological Significance of Exercise and Heat Shock Proteins.....	34
IS-BN02 Control of Gait and Posture: Science and Rehabilitation .....	35
IS-SH03 Gender and Physical Education.....	36
IS-SH04 Talent Identification in Sport .....	37
OP-PM01 Vascular Adaptation.....	38
OP-BN03 Tendons/Stiffness .....	40
OP-PM06 Protein Synthesis .....	43
OP-PM13 Training and Testing: Cycling .....	45
OP-PM10 Heat and Dehydration.....	46
OP-SH03 Physical Activity and Movement Skills.....	48
<b>10:15 - 11:45.....</b>	<b>51</b>
OP-SH05 Health and Paediatric Psychology .....	51
OP-PM11 Training and Testing.....	53
OP-PM41 Muscle: Physiology .....	55
OP-PM48 Physiology: Thermoregulation .....	57
OP-PM31 Physical Activity: Adapted .....	59
OP-PM02 Lipid Metabolism.....	61
OP-BN01 Motor Learning 1.....	64

IS-PM14 Exercise Prescription in Transplant Patients .....	66
IS-SH02 Morals and Ethics in Applied Sports Psychology .....	67
IS-PM05 DEBATE: To Screen or Not To Screen That is the Question: Europe Vs. USA (Sponsored by Philips).....	67
<b>12:00 - 13:15 .....</b>	<b>68</b>
PS-PL02 NEW HORIZONS: In the Role of Exercise in the Treatment of Cardiovascular Disease .....	68
<b>14:00 - 15:00 .....</b>	<b>69</b>
PP-BN01 Sports Biomechanics 1 .....	69
PP-BN02 Cognitive Performance .....	74
PP-BN03 Biomechanics and Injury .....	78
PP-BN04 Motor Learning 1 .....	83
PP-SH06 Physical Education 1 .....	87
PP-SH07 Sociology of Physical Activity .....	92
PP-SH08 Personality, Motivation, Coherence .....	92
PP-SH09 Coaches, Officials and Supporters.....	96
PP-SH10 Sports Psychology 1 .....	100
PP-SH11 Computer Application in Sports .....	104
PP-PM01 Sports Nutrition: Supplements 1 .....	107
PP-PM02 Vascular/Heart Rate/Control.....	112
PP-PM03 Oxidative Stress.....	117
PP-PM04 Exercise and Health in Special Populations 1 .....	121
PP-PM05 Sports Physiology and Testing.....	126
PP-PM06 Environmental Challenge.....	130
PP-PM13 Soccer 2 .....	135
PP-PM20 Molecular Biology .....	139
PP-PM21 Adaptive Physical Activity .....	143
PP-PM22 Physical Activity Promotion and Assessment.....	148
<b>15:00 - 16:00 .....</b>	<b>153</b>

## Invited symposia

### IS-PM01 Sports Nutrition Symposium (sponsored by GSK)

---

#### **BEFORE: NEW DEVELOPMENTS IN PRE-EXERCISE NUTRITION**

WALLIS, G.

*GLAXOSMITHKLINE*

For many years athletes have been recommended to follow a diet that provides sufficient energy and is relatively high in carbohydrate in order to meet the demands of training and competition. The emphasis on carbohydrate reflects its critical role as the major fuel source for exercise. Nonetheless, in the context of training, scientists have started to explore roles for carbohydrate beyond simply meeting energy and fuel requirements. Specifically, carbohydrate availability has been manipulated during training as a means to enhance training adaptation. By using diet and exercise interventions to either reduce or increase carbohydrate availability during training it has been possible to induce favourable metabolic adaptations in previously well-trained individuals. It will however be important to understand the long-term consequences for performance (and health) if such practices are to be recommended to competitive sports participants. In terms of competition, it is important that interventions can be shown to be truly beneficial for real-world performance. Recently, we completed a large-scale study to establish the extent to which selected anthropometric and nutritional factors influence field-based marathon running performance. Using multivariate statistical methods it was identified that in addition to gender, body size and training, pre-race carbohydrate intake can significantly and independently influence marathon running performance. Therefore, recent developments are revealing potential additional benefits of manipulating dietary carbohydrate to enhance training adaptations along with providing new perspectives into the real value of pre-competition carbohydrate intake.

#### **CARBOHYDRATE FEEDING DURING EXERCISE - NEW GUIDELINES BASED ON THE LATEST RESEARCH**

JEUKENDRUP, A.

*UNIVERSITY OF BIRMINGHAM*

Carbohydrate feeding during exercise has been shown to enhance endurance performance. During exercise of 2 hours or more, the delivery of carbohydrates to the muscle is a crucial step and appears to be limited by intestinal absorption. This can, at least partly, be overcome by making use of multiple transportable carbohydrates (for example glucose and fructose). Ingestion of these carbohydrates may result in higher intestinal absorption rates, has been shown to result in higher exogenous carbohydrate oxidation rates and better endurance performance. Multiple transportable carbohydrates can also help fluid absorption and have the potential to reduce gastrointestinal discomfort. In addition it seems possible to increase the absorptive capacity of the intestine by adapting to a high carbohydrate diet. During shorter higher intensity exercise of approximately 1 h duration carbohydrate also appears to improve performance but does this through a completely different mechanisms. Even a mouth rinse with a carbohydrate solution can improve performance suggesting central rather than metabolic effects of carbohydrate. The optimal carbohydrate feeding strategy depends on the duration and intensity of exercise. The current knowledge allows for more detailed guidelines to enhance the delivery of carbohydrates and ultimately improve endurance performance. This presentation will present a series of new guidelines for carbohydrate intake during endurance exercise.

#### **AFTER: HOW CAN PROTEIN HELP MUSCLE RECOVERY?**

VAN LOON, L.

*MAASTRICHT UNIVERSITY MEDICAL CENTRE*

Intact protein, protein hydrolysates, and free amino acids are popular ingredients in contemporary sports nutrition, and are suggested to augment post-exercise recovery. Co-ingestion of protein and/or amino acids with carbohydrate can accelerate muscle glycogen repletion during recovery from exhaustive exercise. However, such an effect is only observed when suboptimal amounts of carbohydrate (<1.0 g/kg/h) are being ingested. As it is not always feasible to ingest such large amounts of carbohydrate (>1.2 g/kg/h) it may be more practical to stimulate skeletal muscle glucose uptake by co-ingesting an insulinotropic amino acid/protein mixture. Furthermore, protein and/or amino acid ingestion stimulates skeletal muscle protein synthesis, inhibits protein breakdown and, as such, stimulates muscle protein accretion during and after resistance or endurance type exercise. This has been suggested to lead to a greater skeletal muscle adaptive response to each successive exercise bout, resulting in more effective muscle reconditioning. Despite limited evidence, some basic guidelines can be defined regarding the preferred type and amount of dietary protein and the timing of protein ingestion to allow optimal post-exercise muscle reconditioning. So far, whey protein seems most effective in stimulating muscle protein synthesis during acute post-exercise recovery. This is likely attributed to its rapid digestion and absorption kinetics as well as its specific amino acid composition. Ingestion of approximately 20 g protein during and/or immediately after exercise is sufficient to maximize post-exercise muscle protein synthesis rates. Co-ingestion of a large amount of carbohydrate or additional free leucine is not warranted to further augment post-exercise muscle protein synthesis when ample protein is already ingested. Future research should focus on the relevance of the acute anabolic response following exercise to optimize the skeletal muscle adaptive response to more prolonged exercise training.

## Invited symposia

## IS-PM02 Eccentric Training and Exercise in Sport

## STRUCTURAL AND MOLECULAR DAMAGE WITH ECCENTRIC EXERCISE

RAASTAD, T., PAULSEN, G., OWE, S.G., LAURITZEN, F., HALLEN, J.

NORWEGIAN SCHOOL OF SPORT SCIENCES

Eccentric exercise has been used as a model to study exercise induced muscle damage for more than four decades (1). Generally, the higher potential for tension development combined with tension at long sarcomere lengths make muscle structures more susceptible for mechanical tearing during eccentric actions than during concentric muscle actions. The degree of damage induced by different eccentric exercise protocols varies with the tension developed, range of motion, exercise volume, speed of elongation and the training status of the muscle. The etiology of eccentric exercise induced muscle damage is not fully understood, but it is believed that the initial step is a mechanical tearing of myofibrillar, cytoskeletal and membrane structures. The initial structural damage can thereafter activate proteases like the calpain system and other protein degradation systems (2). Furthermore, in cases of severe damage an inflammatory response with accumulation of leukocytes is initiated and develops the following days (3). The degree of damage might vary from only minor myofibrillar disruptions to severe cell damage causing segmental fiber necrosis (2, 4). Consequently, the recovery of muscle function may vary from a couple of days to several weeks depending on the degree of damage induced by the exercise protocol (2, 4). At the ultrastructural level myofibrillar disruptions are observed as disorganization of myofilaments and loss of Z-disks (2, 4). A close relation between reduction in force-generating capacity and number of fibers with myofibrillar disruptions, especially the days after exercise, indicates that the structural disruptions directly affects the force-generating capacity of the muscle. After moderate myofibrillar disruptions it seems like sarcomere structure and muscle function can be regained within a week, however, if segmental necrosis takes place, the regeneration process may take more than 1-2 months (2, 4). The remodeling process after moderate myofibrillar disruptions involves exchange of myofilaments and intermediate filaments (5), whereas the remodeling process after segmental necrosis involves leukocyte accumulation and later regeneration of fiber segments through satellite cell fusion into connecting myotubes (6). Serial addition of new sarcomeres has been indicated as part of the remodeling process and suggested as one possible mechanism behind the repeated bout effect observed after the first bout of eccentric exercise. A heat shock protein response is also a part of the remodeling process and may also contribute to strengthen myofibrillar structures after the first bout (7). 1 Friden et al. *Experientia* 37 (5):506-507, 1981. 2 Raastad et al. *Med Sci Sports Exerc.* 42 (1):86-95, 2010. 3 Paulsen et al. *Med Sci Sports Exerc.* 42 (1):75-85, 2010. 4 Lauritzen et al. *J Appl Physiol* 107 (6):1923-1934, 2009. 5 Yu et al. *Histochem. ## ECCENTRIC EXERCISE TRAINING IN ELITE SKIING

VOGT, M.

UNIVERSITY OF BERN

Introduction: Competitive alpine skiing is very different compared to recreational skiing and other sports. Heart rate and blood lactate measurements during competition show that physical demand during these 45 to 120 seconds tasks is maximal and that the values can even exceed the maximal values measured during appropriate lab performance testing. Moreover, the load on skeletal muscles during competitive alpine skiing is very high. Compared to other competitive sports, muscle recruitment pattern during alpine skiing is special and characterized by a preponderance of eccentric over concentric activity. Methods: In the course of the optimization of training methods which account for high demands on energy turnover and strength during elite alpine skiing, we constructed an eccentric ergometer. The device is software controlled, can deliver a maximum of 5'000 W of power during cyclic exercise, uses a biofeedback system to adjust training loads and allows for quantitative assessment of required vs. applied power (coordination). We have used the eccentric ergometer in various training settings with patients as well as with junior and elite alpine skiers and selected other athletes. In addition to conventional strength training, elite alpine skiers trained on the eccentric ergometer ones or twice per week during their summer preparation period. A typical training session consisted of four 4- to 5-minutes intervals. Results: The summary of selected results from different training groups indicate that maximal isometric strength, jump heights and performance in counter movement jumps can further be increased in elite skiers within six to eight weeks of eccentric exercise training. Without getting muscle soreness elite slalom skiers were able to increase their eccentric training load by over 100% within only 5 exercise sessions. Athletes were able to massively improve coordination of eccentric force development. For slalom skiers we have some indication that the quality of eccentric force development is best in those athletes with the best world rank position. Discussion: Our results indicate that cyclic eccentric exercise further improves maximal and explosive strength and the quality of (eccentric) force development in junior and elite alpine skiers. The mode of muscle action during alpine skiing requires high power generating and stabilizing leg and trunk muscles as well as well developed coordination for eccentric muscle activity. Cyclic eccentric training therefore appears to be a supporting approach to optimize performance and prevent injury in elite alpine skiing. REFERENCES Berg HE, Eiken O. ## ECCENTRIC EXERCISE TRAINING AS A NOVEL REHABILITATION MODALITY

MARCUS, R.L., DIBBLE L.E., LASTAYO, P.C.

UNIVERSITY OF UTAH

Overcoming muscular impairments is often one of the primary objectives of rehabilitation following injury or disease. More specifically, the recovery of muscle size, strength, power and mobility are critical goals of rehabilitation. At the very least, rehabilitation professionals seek to minimize these muscle impairments in those where deterioration is inevitable. While eccentric training models have historically been employed to induce muscle damage or improve sport performance, chronic exposure to eccentric muscle contraction is increasingly being employed to overcome muscle impairments in patient populations. Because much greater force (2 to 3 times greater) can be produced eccentrically than either isometrically or concentrically, eccentric training has the capability of "overloading" muscle to a greater extent and enhancing muscle mass, strength and power than concentric exercise. Importantly, these benefits of eccentric training are

achievable with a minimal energetic/exertion cost, making eccentric training ideally suited for patients who are often exercise-intolerant. Our research has focused on the application of eccentric exercise training in adults who suffer from muscle loss and its clinical consequences, including those: recovering from total knee arthroplasty and anterior cruciate ligament reconstruction; living with diabetes, Parkinson disease, and multiple sclerosis; survivors of stroke and cancer; and those who are frail and at high fall risk. This symposium will present data from our laboratory and from the literature that illustrates both the application and impact of eccentric training to mitigate loss of muscle, muscle fatty infiltration and the functional sequelae adversely affecting needy populations, in a rehabilitation setting. ## Invited symposia

### IS-PM03 Cardiovascular Imaging in Sport Science: What does the future hold?

#### EXERCISE AS VASCULAR MEDICINE: ULTRASOUND INSIGHTS IN EXERCISE AND HEALTH

GREEN, D.

LIVERPOOL JOHN MOORES UNIVERSITY

In this symposium I will briefly present a history of the study of the circulation, from Harvey's proofs, through the era of plethysmography, to sophisticated contemporary imaging approaches. Conceptually, I will develop an argument that much of the beneficial impact of exercise, in terms of cardiovascular (CV) risk, may relate to direct haemodynamic effects of episodic exercise bouts on the vasculature rather than modulation of traditional CV risk factors, as has been previously thought. Evidence will be presented which illustrates the impact of forces such as vascular shear stress and transmural wall pressure on adaptations in the function and structure of the arterial tree, at conduit, resistance and microvascular levels. The possibility of both anti- and pro-atherosclerotic effects of exercise will be raised. New studies, which follow on from the seminal work of Folkow pertaining to the vascular implications of the Law of Laplace, will also be presented. The concept that exercise training regimes might be devised around optimising haemodynamic signals will be explored. Finally, I will present some ideas about the future directions of in vivo human vascular research, particularly the way in which new technological advances may lead our future understanding of the integrative responses to exercise and adaptations to physical activity and exercise training.

#### CARDIAC MAGNETIC RESONANCE IMAGING IN ATHLETES

SCHARHAG, J.

UNIVERSITY OF POTSDAM

Cardiac magnetic resonance imaging (CMR) is considered as the most exact diagnostic tool to examine the heart non-invasively, and allows detailed analyses of cardiac structures and functions in physiological and pathophysiological altered hearts. Therefore, CMR is considered as the non-invasive gold standard to examine the heart. On the other hand, compared to echocardiography, CMR is more time consuming and expensive, and therefore, less data are available in athletes than for echocardiography. Nevertheless, within the last decade a considerable number of CMR studies has been performed by different scientific groups and examined the heart in athletes. Due to different techniques and different study populations, which usually are small, in some aspects different results have led to different interpretations of cardiac adaptations in the athlete's heart. Whereas adaptive changes in the athlete's left ventricle have been described more or less uniform in endurance athletes presenting an eccentric hypertrophy, only little data are available for strength trained athletes. Based on an own study, anabolic free strength trained athletes only presented a very moderate eccentric, but not concentric, left ventricular hypertrophy when related to the lean body mass and compared to sedentary controls matched for body dimensions. For right ventricular changes in athletes, still only a little number of studies exists. In endurance athletes most study groups report a harmonic eccentric hypertrophy of the left and the right ventricle. Nevertheless, some reports on right ventricular pathologies detected in endurance athletes, which are thought to be induced by repetitive excessive endurance exercise over years, warrant further (multi-centre) studies with higher numbers of athletes and similar CMR techniques to examine this possible maladaptation in the future. Another advantage of CMR is its high sensitivity to detect cardiac abnormalities and pathologies. By the use of special CMR sequences and contrast media, acute myocardial oedema during and chronic scars after myocarditis or myocardial infarction can be detected. In addition, mild maladaptive changes or pathologies can be detected earlier by CMR than by echocardiography, such as hypertrophic cardiomyopathy (especially in the apical region), arrhythmogenic right ventricular cardiomyopathy (ARVC) or left ventricular non-compaction cardiomyopathy (LVNC). Furthermore, it may be possible in the future to allow a better risk stratification for adverse cardiac events or sudden cardiac death in athletes if the above mentioned pathologies are examined systematically in athletes by cMRI. The lecture will give an overview on the present results of CMR studies in athletes and perspectives on future studies.

#### STRAIN AND TORSION MECHANICS BY ECHOCARDIOGRAPHY DURING ACUTE EXERCISE AND IN RESPONSE TO ENDURANCE TRAINING.

OBERT, P.

UNIVERSITY OF AVIGNON

During the cardiac cycle, the myocardium deforms in longitudinal (L), circumferential (C) and radial (R) planes. As a result of obliquely orientated fibers, the left ventricle (LV) twists along its longitudinal axis during systole and rapidly untwists during early diastole. The latter (consequence of both active relaxation and elastic recoil) promotes LV "suction" and filling by increasing intraventricular (base to apex)

and atrio-ventricular gradients. Evaluation of myocardial deformation and torsion by echocardiography (speckle tracking imaging, STI) has been validated against MRI. STI provides sensitive indexes of myocardial relaxation and contractility, relatively independent of loading conditions. Notomi first demonstrated in the transition from rest to exercise an increase in LV torsion (LVT) and untwist rate during early diastole. During a triangular exercise, we reported that L strain rapidly plateaued while LVT and C strain gradually increased. Both studies underlined the key role of untwisting in LV filling. No L strain changes were documented in response to handgrip stress (Stefani et al 2007), demonstrating that certain conditions (eg hemodynamic load,  $\beta$ -adrenergic stimulus,...) have to be fulfilled. Based on conventional echo, previous studies reported « supernormal » LV function in endurance athletes. Whether strain and torsional mechanics change in response to endurance training remains poorly understood. Recent data (Nottin et al. 2008) demonstrated at rest similar LV L, C and R strain/strain rate but reduced LVT in competitive cyclists compared to sedentary controls. Similar results regarding LV torsional dynamics have been obtained by Zocalo et al (2007) in professional soccer players. These results were related to the pronounced resting bradycardia (and probably lower sympathetic drive) and might be indicative of « supernormal functional reserve » in the training state. Very recent findings from our group (unpublished data) have confirmed this hypothesis, as greater LVT reserve (enhanced apical rotations) during effort was demonstrated in trained cyclists. Normal resting LV L, C and R strain/strain rate have also been established in endurance athletes (Teske et al 2010, Galderisi et al 2010). Of note, different strain and torsional profiles at rest have been documented by others. Compared to sedentary controls, Richand et al (2007) reported similar C and R but reduced L strain in soccer players while Simsek et al (2010) demonstrated greater L strain in highly-trained aerobic/anaerobic athletes. Galderisi et al (2010) showed similar LVT in top-level rowers and controls, despite significant bradycardia in the athletes. Finally, recent findings from Weiner et al (2010) highlighted enhanced twist (improved apical rotation)/untwist rate in recreational rowers after an endurance training program. Differences in training state (quantity, quality, and length), methods (STI vs TDI-derived strain, cross-sectional vs longitudinal) might explain these controversial data and further studies will be required.

### OP-BN05 Fatigue

#### INTERPOLATED TWITCH TECHNIQUE: INTERESTING TECHNIQUE DURING FATIGUE EXERCISE?

MATKOWSKI, B.1, PLACE, N.2, LEPELERS, R.1, WESTERBLAD, H.3, MARTIN, A.1

1: UNIVERSITÉ DE BOURGOGNE (DIJON, FRANCE), 2: UNIVERSITÉ DE GENÈVE (GENÈVE, SWITZERLAND), 3: KAROLINSKA INSTITUTET (STOCKHOLM, SWEDEN)

**Introduction** Muscle fatigue results from an intense and/or prolonged exercise and progressively leads to a reduction in maximal voluntary contraction (MVC) force (Gandevia, 2001). This reduction in MVC force is transient and can be assigned to central and/or peripheral mechanisms. To assess the amount of central fatigue, the interpolated twitch technique (ITT) is commonly used. However, the validity of this technique is discussed in the literature (e.g. Horstman, 2009; Enoka, 2009) and recently Place et al. (2008) demonstrated with mouse intact single fibres that the ITT takes into account peripheral properties of fatigue. The present study was designed to assess the effect of fatigue on the interpolated twitch amplitude applied on repeated tetanic stimulation induced by electromyostimulation (EMS) in human quadriceps muscle. **Methods** Experiments were performed on 9 healthy men. Twitch was evoked on (superimposed twitch) and after (potentiated twitch) each of the 15 repeated tetanic stimulations (6s on - 6s off), performed in isometric condition with a knee angle of 90°. The intensity used for the EMS-induced contractions was set to 20% of MVC and kept constant for the 15 contractions. MVC have been performed before and after the EMS-induced contractions. Twitches amplitudes (superimposed and potentiated ones) and EMS-induced torque were recorded. **Results** The repeated tetanic contractions induced by EMS resulted in a decreased of MVC torque ( $-14.1 \pm 6.9\%$ ;  $P < 0.001$ ). The EMS-induced torque and the potentiated peak twitch were significantly depressed ( $-60.0 \pm 7.3\%$  and  $-10.3 \pm 5.9\%$  respectively;  $P < 0.001$ ), whereas the superimposed twitch amplitude was significantly increased ( $24.6 \pm 13.8\%$ ;  $P < 0.001$ ) at the end of the 15 repeated tetanic stimulations. **Discussion** The results showed a progressive increase in the superimposed twitch amplitude, whereas the EMS-induced torque decrease. This can be interpreted as central fatigue. We also noted a progressive decrease in the potentiated twitch amplitude, evidencing peripheral fatigue. The time course of the increase in the superimposed twitch amplitude combined with the reduction in the potentiated twitch amplitude indicate that the loss of force could mainly be attributed to a reduction in motor unit discharge rate rather than full motor unit derecruitment, and/or to a failure in the excitation-contraction coupling process (Place et al., 2008). **References** Enoka RM. #### ACUTE AND DELAYED SSC FATIGUE EFFECTS ON TREADMILL RUNNING: MEANINGFUL INITIAL NEURO-MECHANICAL ADJUSTMENTS

MORIO, C., BARLA, C., MESURE, S., BERTON, E., NICOL, C.

OXYLANE RESEARCH

**ACUTE AND DELAYED SSC FATIGUE EFFECTS ON TREADMILL RUNNING: MEANINGFUL INITIAL NEURO-MECHANICAL ADJUSTMENTS** Morio, C.1,2, Barla, C.1, Mesure, S.2, Berton, E.2, Nicol, C.2 1: Oxylane Research (Lille, France), 2: UMR 6233 (Marseille, France) **Introduction** Stretch-shortening cycle (SSC) defines natural, but challenging forms of ground locomotion (Komi 2000). Due to necessary initial adjustments, the SSC pattern is usually analysed once stabilized. In case of fatigue, however, meaningful compensatory and/or protective neuro-mechanical adjustments are expected to take place in the early exercise. Fatigue induced by exhaustive SSC exercise is of particular interest as it includes acute functional defects, but also delayed ones associated with muscle soreness and potential influence of III and IV muscle afferents on the neural drive (Nicol et al. 2006). This fatigue paradigm was used to compare the neuro-mechanical adjustments observed during the first 3 min of a treadmill run and once stabilized. **Methods** Exhaustive SSC exercise was performed on a sledge apparatus by 8 male healthy subjects who repeated series of 25 bilateral jumps, with inter-series rests of 3 min. Rebound height was set at 80% of maximal rebound height. SSC fatigue was quantified before (PRE), after (POST) and two days (D2) later by a maximal drop jump test. The induced neuro-mechanical changes were examined in the early and stabilized phases (first and third minutes) of a submaximal treadmill run through 3D kinematics and electromyography recordings of 8 major muscles of the right lower limb. Appropriate two-way ANOVA analyses and Tukey post-hoc comparisons were performed with a 0.05 level of significance. **Results** Maximal rebound height decreased similarly by 6% at POST and D2. Muscle soreness was elevated up to day 4. In the treadmill runs, initial neuro-

mechanical adjustments occurred, but they remained similar in trends and amplitude despite fatigue. Comparison of the stabilized running patterns revealed most changes at D2, which presented a  $12 \pm 8\%$  increase in lower limb stiffness, with associated  $7 \pm 23\%$  increased vastii preactivation ( $33 \pm 45\%$  at the first minute), straighter knee at impact and reduced subsequent flexion. This contrasted with larger ankle eversion and midfoot abduction. Discussion In circumstances where DOMS is involved, reduced knee flexion could aim at preventing further muscle pain in vastii muscles (Dutto & Braun 2007), but at the expense of impact shocks that could explain the associated ankle and foot protective kinematic changes. It is noteworthy that the D2 running pattern was modified since its first minute and remained as such. At this expected time of inflammation within the exercised muscles, activation of III and IV muscle afferents might have contributed to the protective neural strategies. References Komi PV (2000). ### **CAN INTERVENTIONAL PAIRED ASSOCIATIVE STIMULATION MODIFY FATIGUE RESISTANCE DURING SUSTAINED ISO-METRIC MAXIMAL VOLUNTARY CONTRACTION?**

AVELA, J.1, PELTONEN, J.1, KUMPULAINEN, S.1, GRUBER, M.2, CRESSWELL, A.3, PEURALA, S.4, LINNAMO, V.1

1: UNIVERSITY OF JYVÄSKYLÄ, FINLAND, 2: UNIVERSITY OF KONSTANZ, GERMANY, 3: UNIVERSITY OF QUEENSLAND, AUSTRALIA, 4: UNIVERSITY OF JYVÄSKYLÄ, FINLAND

**INTRODUCTION** Interventional paired associative stimulation (IPAS) has been used to study motor learning and utilised in motor control therapies after brain injury (Thickbroom 2007). IPAS includes combination of peripheral nerve stimulation (PNS) and transcranial magnetic stimulation (TMS) at the motor cortex. In central fatigue, muscle force is limited by insufficient central drive to the motor neurons (Gandevia 1998). Because IPAS has potential to increase or decrease motor cortex excitability, the purpose of this study was to examine whether IPAS can modify supraspinal contribution of central fatigue. **METHODS** 30 subjects were randomly divided into two groups separated by the interstimulus interval (ISI) between PNS and TMS (20 ms and 50 ms). IPAS protocol consisted of 200 pairs (0.2 Hz) of PNS to the common tibial nerve and TMS aimed into Soleus motor cortex. Corticospinal and spinal excitability were tested with the TMS and H-reflex, respectively. Fatigue resistance was calculated as the relative force reduction during a 15 second sustained isometric maximal voluntary contraction (MVC). In addition, twitch occlusion technique was used at the end of the contraction to reveal the level of central activation. **RESULTS** ISI50 group demonstrated a significant increase in the average size of the motor evoked potential (MEP) with a value of  $1.92 \pm 0.41$  ( $p=0.019$ ) after IPAS. Conversely, ISI20 group showed a significant reduction in MEP size with a value of  $0.75 \pm 0.12$  ( $p<0.023$ ). In both groups, the H/M ratio as well as M-max remained unchanged. Force decreased significantly at the end of the 15 second sustained MVC (11-13%) before and after IPAS. However, this reduction was not different between the groups. In addition, central activation did not change significantly after IPAS with neither of the groups. However, in both groups significant negative correlations were found between change in fatigue resistance and change in superimposed twitch torque ( $r=-0.61$  and  $-0.58$ ,  $p<0.05$ ). **DISCUSSION** Current results highlight the timing-specificity of the two concurrent stimuli during IPAS targeted to Soleus motor cortex. 15 second sustained MVC failed to induce remarkable central fatigue (only from 1 to 2%). However, because of the unchanged H/M ratio and the aforementioned negative correlation, it could be suggested that IPAS may have potential to modify the supraspinal mechanisms of central fatigue. **REFERENCES** Thickbroom GW. (2007). Exp Brain Res 180(4):583-93. Gandevia SC. (1998). Acta Physiol Scand. 162(3):275-83.

### **NEUROMUSCULAR FATIGUE AFTER TREADMILL SHORT AND LONG SPRINTS**

TOMAZIN, K.

UNIVERSITY OF LJUBLJANA, FACULTY OF SPORT

Tomazin, K.1,2 Morin, JB.2, Strojnik, V.1, Millet GY.2 1: University of Ljubljana, Faculty of Sport (Ljubljana, Slovenia), 2: Université de Lyon, F-42023, (Lyon, France) and Jean Monet University (Saint-Etienne, France) **Introduction** A slight to substantial decrease in speed characterize single, maximal sprints on Olympic distances (100, 200 and 400-m). Neuromuscular alterations due to high force output demands during sprint support phases are probably one of the main reasons for speed decrements towards the end of a sprint. Although many studies have investigated neuromuscular fatigue after different high-intensity whole body exercises (>60 s) performed in the laboratory conditions (Strojnik and Komi, 1998; Tomazin et al. 2008), very little is known about central and peripheral fatigue during maximal, single sprints. The aim of this study was to compare the aetiology of fatigue following maximal sprints of different Olympic distances. **Methods** Eleven subjects ( $24 \pm 4$  years,  $73 \pm 6$  kg,  $179 \pm 6$  cm) performed 100, 200 and 400-m sprints on a motorized instrumented treadmill (Morin et al. 2010). The neuromuscular function evaluated before (Pre), 30 s (Post) and 30 min after sprints (Post30), consisted in determining maximal voluntary knee extensors torque (MVC), maximal voluntary activation of knee extensors (%AL), single twitch (TW) and doublets low- (10 Hz, Db10) and high-frequency torque (100 Hz, Db100). **Results** MVC was not significantly altered following 100 and 200-m sprints but decreased by  $14 \pm 13\%$  ( $P<0.001$ ) after the 400-m and went back to initial values Post30. Only non-significant decrease in %AL ( $-4 \pm 7\%$ ) was obtained post 400-m. Db100 decreased only Post 200-m ( $-8 \pm 9\%$ ;  $P<0.001$ ) and 400-m ( $-14 \pm 12\%$ ;  $P<0.001$ ) sprints. Tw and ratio Db10/Db100 decreased Post 100-m ( $-9 \pm 10.1\%$ ;  $P<0.05$  and  $-7 \pm 6\%$ ;  $P<0.01$ , respectively), 200 ( $-19 \pm 12\%$ ;  $P<0.001$  and  $-11 \pm 7\%$ ;  $P<0.001$ , respectively) and 400-m ( $-34 \pm 18\%$ ;  $P<0.001$  and  $25 \pm 10\%$ ;  $P<0.001$ , respectively) sprints and were not recovered Post30 after all sprints. **Discussion** Single maximal sprints of 100 to 400-m induce progressive and substantial low-frequency peripheral fatigue. Despite altered single or paired stimulations, MVC strength loss (i.e. conventional definition of fatigue) was detected only after the 400-m sprint. **References** Morin JB, Samozino P, Bonnefoy R, Edouard P, Belli A (2010). ### **THE EFFECT OF FATIGUE ON THE BIOMECHANICAL PROPERTIES OF OBSTACLE CROSSING**

PATIKAS, D.1, ANTONOPOULOS, C.2, BASSA, E.2, KOUTLIANOS, N.2, MICHAILIDIS, C.2, KOTZAMANIDIS, C.2

1: TEFAA-AUTH, (SERRES, GREECE), 2: TEFAA-AUTH, (THESSALONIKI, GREECE).

**Introduction** Fatigue, as an element of everyday life, physical activity and as a symptom in different pathologies, influences the accuracy of a movement (Welsh and Segal 1996). On the other hand, obstacle crossing is a common task, which is quite challenging for elderly people or people with disabilities. In these cases fatigue could further increase the risk of falling. However, it is still unknown the effect of fatigue on the biomechanical and neuromuscular properties during obstacle crossing. **Methods** Fourteen untrained male volunteers (age:  $23 \pm 5$  years) walked over an obstacle of 10% or 20% of their lower limb length, in random order. Then they were fatigued walking/running on a treadmill until exhaustion using modified Bruce protocol. Immediately and five minutes after, the obstacle crossing was re-evaluated. We captured the vertical ground reaction forces (vGRF), the kinematics of the lower limbs and the electromyogram (EMG) of

the medial gastrocnemius, soleus and tibialis anterior of the trailing foot. A two way ANOVA with repeated measurements was used for statistical analysis ( $p < 0.05$ ). Results The EMG for the three examined muscles of the trailing foot was not affected by the obstacle height and no changes were observed before and after fatigue during obstacle crossing. The hip and knee of the leading limb was more flexed when increasing the obstacle height, but fatigue did not induce any significant change. The trailing limb showed significantly increased knee and ankle joint angles when increasing the obstacle height. The main effect for fatigue and the interaction was not significant for the trailing limb. The distance of the trailing foot from the 10% height obstacle was significantly shorter after fatigue and recovered after 5 minutes. No differentiation was observed for the distance of the leading limb from the obstacle when stepping on the ground after the obstacle. Finally, the vGRF was significantly higher after fatigue independent of the obstacle height and recovered after 5 minutes rest. Discussion Our results suggest that kinematics and EMG properties of the examined muscles during obstacle avoidance of two different heights are not affected by fatigue induced by sustained running until exhaustion. Although the higher vGRF on the support (trailing) foot may increase the risk of falling it can be concluded that at least in healthy young persons, fatigue can only have minor effects on the obstacle avoidance pattern. However, further investigation is required in more sensitive to falls populations and during more challenging obstacle heights. References Welsh DG, Segal SS (1996). *Circulation Research*, 79, 551-559.

## THE EFFECTS OF RUNNING FATIGUE ON OVERGROUND IMPACT ACCELERATION

CLANSEY, A., HANLON, M., WALLACE, E., LAKE, M.

UNIVERSITY OF ULSTER

THE EFFECTS OF RUNNING FATIGUE ON OVERGROUND IMPACT ACCELERATIONS Clansey, A.1, Hanlon, M.1, Wallace, E.1, Lake, M.2 1:UUJ (Belfast, NI), 2: LJMU (Liverpool, UK) Introduction Fatigue can have considerable effects on lower limb mechanics during running and has been linked with the development of overuse injuries (Dierks et al., 2010). It has been reported that as a runner progresses over the course of a run the onset of neuromuscular fatigue causes the protective mechanisms of the muscle to be less effective in coordinating limbs and reducing leg impact accelerations (Mizrahi et al., 2000). However, it is still unknown how different fatigue levels subsequently affect impact accelerations of trained distance runners. The aim of this study was to investigate the effects of different levels of running fatigue on subsequent impact accelerations during overground running. Methods Ten runners ( $32.5 \pm 11$  yrs;  $73 \pm 13$  kg;  $1.77 \pm 9.4$  m;  $13.8 \pm 1.9$  km/h lactate threshold (LT) at 3.5 Mm) performed three tests (Pre, Mid & Post) of 8 acceptable overground running trials at 4.5 m/s ( $\pm 5\%$ ). Between tests each subject ran on a treadmill (HP Cosmed, UK) for 20 min at their LT speed. Ratings of perceived exertion (RPE) were taken at the 3rd and 20th min of the treadmill run. Subjects had two accelerometers (Noraxon, USA) attached to the distal tibia and forehead. For each trial, three seconds of vertical acceleration data was collected at 1500 Hz. A repeated measures ANOVA was used to assess the significance of run duration (3 time levels) on acceleration measures (alpha level of  $p < 0.05$ ). Results Subject RPE scores increased from 11.8 to 15 at the end of the 1st 20-min run and then to a further 18.2 by the end of the second 20-min run. Both peak tibial acceleration (12.4 to 13.4 g) and peak head acceleration (1.4 to 1.7 g) significantly increased from the Pre to Post test. However no significant differences were found in both head and tibial accelerations between pre and mid test. Discussion Results showed that tibial and head accelerations significantly increased with fatigue levels (mean changes of 8% and 21%, respectively). Greater accelerations at the head and tibia with fatigue may be due to a possible reduction in shock attenuation properties of the musculoskeletal system (Mizrahi et al., 2000). Further investigation is still required into possible kinematic factors that may be linked with these fatigue-induced increases in tibial and head accelerations (Dierks et al., 2010). ## EFFECT OF ACUTE EXERCISE INTENSITY ON BRACHIAL ARTERY ENDOTHELIAL FUNCTION IN HUMANS

DAWSON, E.A., BIRK, G.K., CABLE, N.T., THIJSEN, D.H.J., GREEN, D.J.

LIVERPOOL JOHN MOORES UNIVERSITY

Introduction: Whilst the effects of exercise training on vascular function have been well studied, less is known about the influence of acute exercise on conduit artery vasodilator function. Previous data may be confounded by methodological issues such as exercise intensity and the timing of post-exercise measurements. We examined brachial artery flow mediated dilation (FMD) before, immediately after and 1, 2 and 24 hours following 3 bouts of acute exercise at different intensities. Methods: Ten healthy males ( $22 \pm 1$  years) were randomly assigned to undertake 30 min cycling at 50, 70 and 85% maximal heart rate (HRmax). Brachial artery FMD was assessed using high resolution echo-Doppler. We also calculated the shear rate area-under-the-curve (from cuff deflation to peak dilation; SRAUC) as the eliciting stimulus for FMD. Results: Exercise at 50, 70 and 85% HRmax was performed at  $99 \pm 7$ ,  $129 \pm 3$  and  $153 \pm 5$  bpm. Two-way ANOVA demonstrated no change in brachial artery FMD at any time point at 50% HRmax. There was a significant decrease immediately post-exercise at 70% ( $6.7 \pm 2.1$  vs  $4.5 \pm 2.4\%$ ;  $P = 0.016$ ) which then returned to near baseline levels at 1 ( $5.9 \pm 2.7\%$ ), 2 ( $6.4 \pm 2.7\%$ ) and 24hr ( $6.6 \pm 2.5\%$ ). There was also a significant decrease in FMD post-exercise at 85% HRmax ( $6.1 \pm 1.2$  vs  $3.4 \pm 1.2\%$ ;  $P < 0.001$ ) which subsequently normalised (1hr:  $6.8 \pm 2.7\%$ ; 2hr:  $5.6 \pm 2.1\%$ ; 24hr:  $6.1 \pm 2.5\%$ ). No differences were evident in baseline diameter or SRAUC by 2-way ANOVA. Conclusion: These data indicate that the intensity of an acute exercise bout impacts conduit artery vasodilator function in a differential and time-dependent manner. Higher intensities were associated with immediate post-exercise reductions in FMD, which were not due to decreased SR stimulus presentation. Previous studies have suggested that elevated oxidative stress or inflammation associated with intense acute exercise may decrease vasodilator function. All FMD data were normalised by 1 hour post-exercise, suggesting any impairment is transient. These findings of a time and dose-dependent response inform our understanding of the acute stimuli responsible for training-induced arterial adaptations and indicate that care should be taken when interpreting post-exercise data.

## EFFECT OF INTENSE INTERVAL TRAINING ON BLOOD PRESSURE AND HEMODYNAMICS IN SUBJECTS WITH ESSENTIAL HYPERTENSION

JENSEN, L.G., NYBERG, M., THANING, P., HELLSTEN, Y., MORTENSEN, S.P.

UNIVERSITY OF COPENHAGEN, DENMARK

**Introduction** Roughly 1 billion people worldwide suffer from hypertension and extensive work has been done to evaluate pharmacological and non-pharmacological interventions. Regular physical activity of moderate intensity is known to reduce blood pressure but the effect of high intensity intermittent exercise on blood pressure is less clear. Moreover, the mechanisms behind the blood pressure lowering effects of exercise remain unsolved. Nitric oxide (NO) and vasodilator prostanooids (PGs) are potent vasodilators that contribute to blood pressure regulation. The present study examined the effect of intensive interval training on blood pressure and the role of the NO/PG system in this response. **Methods** Ten subjects diagnosed with essential hypertension ( $47 \pm 4$  years,  $171 \pm 11$  cm,  $80 \pm 24$  kg (S.E.)) and ten normotensive control subjects ( $46 \pm 3$  years,  $177 \pm 8$  cm,  $76 \pm 9$  kg), performed 8 weeks of high intensity intermittent exercise training (1 hour cycling sessions 3-4 times per week, ~40% of training time > 80% of heart ratemax). Before and after the training period, the subjects participated in an experiment in which intra-vascular blood pressure and leg hemodynamics were measured at rest and during low, medium and high intensity one-leg knee-extensor exercise. The measurements were performed with and without inhibition of NO and PGs by infusion of L-NMMA and Indomethacin into the femoral artery. **Results** Training increased ( $P < 0.05$ )  $VO_{2max}$  by ~10% in both groups and decreased ( $P < 0.05$ ) mean arterial pressure by 7 mmHg in the hypertensive group only. The reduction in blood pressure was present both at rest and during all exercise intensities. Blocking the NO/PG system fully reversed the training induced reduction in resting and exercising blood pressure. **Discussion** The finding of a reduction in blood pressure in individuals with essential hypertension highlights that high intensity interval training is an efficient non-pharmacological intervention. The finding of full reversal of the blood pressure reduction by NO and PG blockade strongly indicates that one or both of these systems is up regulated with training in hypertensive subjects and contribute to the training-induced reduction in blood pressure. **Funding:** Danish Medical Research Council

## THE EFFECT OF CIRCUIT TRAINING ON RESTING HEART RATE VARIABILITY, CARDIOVASCULAR DISEASE RISK FACTORS AND FITNESS IN HEALTHY UNTRAINED ADULTS

VRACHIMIS, A., HADJICHARALAMBOUS, M., TYLER, C.

ROEHAMPTON UNIVERSITY, UNIVERSITY OF NICOSIA (CYPRUS)

**THE EFFECT OF CIRCUIT TRAINING ON HEART RATE VARIABILITY, CARDIOVASCULAR DISEASE RISK FACTORS AND FITNESS IN HEALTHY UNTRAINED ADULTS** Vrachimis, A.1,2, Hadjicharalambous, M.2, Tyler, C.1 1: Roehampton University (London, UK), 2: University of Nicosia (Cyprus) **Introduction** Heart rate variability (HRV) is a clinical predictor of cardiovascular disease (CVD) morbidity and mortality (e.g. Tsuji et al., 1994). Studies have shown that aerobic training has a positive effect on resting HRV (e.g. Lee et al., 2003); however, not much is known about the effect of circuit training (CT) on resting HRV. The main purpose of this study was to examine whether CT has a positive effect on resting HRV. The secondary purpose was to investigate the effect of CT on other CVD risk factors and several fitness components. **Methods** Twelve healthy untrained adults (mean (SD) age 23.3 (3.2) years, height 166.9 (8.4) cm, weight 67.6 (16.7) kg) performed 12 bodyweight exercises in a circuit format, 3 d/wk for 6 weeks. In weeks 1 and 2, 3 and 4, and 5 and 6 they had to complete 1, 2, and 3 circuits per session respectively. In weeks 1, 3 and 5 and weeks 2, 4 and 6 the objective was to complete 15 and 20 repetitions respectively for each exercise. Pre and post intervention time- and frequency-domain, and non-linear methods of resting HRV and blood pressure (Systolic: SBP; Diastolic: DBP) were measured. The time-domain measures were heart rate, SD of the RR intervals, number and proportion of adjacent RR intervals more than 50 ms different. The frequency-domain measures were very low, low (LF), and high (HF) frequency power, LF and HF in normalised units, and the ratio of LF to HF. The non-linear measures were the SD calculated on the vertical axis (SD1) and on the horizontal axis (SD2) of the Poincare plot, and the ratio of SD1 to SD2. In addition, body composition, blood lipids, glucose,  $VO_{2max}$ , upper body and abdominal and hip flexor muscular endurance, back and handgrip strength were assessed. Data were analysed using paired t-tests. **Results** There was no effect of CT on any of the measures of resting HRV (all  $P > 0.05$ ). SBP ( $P = 0.04$ ) and DBP ( $P = 0.03$ ) decreased, lean body weight ( $P = 0.03$ ) increased, whereas the other CVD risk factors did not change after CT. Upper body muscular endurance ( $P < 0.001$ ) and back strength ( $P = 0.02$ ) increased, while the rest of the fitness components were not affected. Blood lipids (total cholesterol, lipoproteins, triglycerides) and glucose did not change with CT. **Discussion** The present study suggests that CT involving bodyweight exercises has no effect on resting HRV. These results are concordant with the findings of Liu (2010). However, this type of training may decrease the risk for development of CVD by reducing arterial blood pressure as well as by enhancing muscular strength and endurance. **References** Lee et al. ## PHYSICAL ACTIVITY STATUS AND OXIDISED LOW-DENSITY LIPOPROTEIN CONCENTRATIONS IN OLDER ADULTS

PARK, J.H., MIYASHITA, M., TAKAHASHI, M., HARADA, K., TAKAIZUMI, K., KIM, H.S., SUZUKI, K., NAKAMURA, Y.

WASEDA UNIVERSITY

**Introduction** Although oxidised low-density lipoprotein (LDL), a risk marker for cardiovascular disease (Itabe and Ueda, 2007), increases with age (Cakotay et al., 2008), regular physical activity ameliorates oxidative stress and prevents the accumulation of lipids (Li, 1993). However, it remains unclear whether oxidised LDL concentrations differ with physical activity status in older adults. The purpose of this study was to examine the relationship between the amount of physical activity and oxidised LDL concentrations in older adults. **Methods** A total of 27 older adults (aged  $69.9 \pm 0.8$  years, mean  $\pm$  SEM; 16 females and 11 males) were analysed in a cross-sectional design. Prior to the blood collection, participants were asked to wear an uniaxial accelerometer for 4 consecutive weeks for the determination of physical activity status. After a 48-h period of physical activity avoidance and a 10-h overnight fast, fasting venous blood samples were obtained from each participant. **Results** The amount of moderate to vigorous physical activity determined by the accelerometer was  $173.2 \pm 14.6$  min/week (range; 62.6–312.9 min/week). Fasting plasma oxidised LDL concentrations and plasma monocyte chemoattractant protein-1 concentrations were negatively correlated with the amount of physical activity ( $r = -0.409$ ,  $P = 0.034$ ;  $r = -0.385$ ,  $P = 0.047$ , respectively). The amount of physical activity was significantly correlated with fasting serum triacylglycerol ( $r = -0.415$ ,  $P = 0.031$ ), fasting serum high-density lipoprotein cholesterol ( $r = 0.405$ ,  $P = 0.036$ ) or fasting plasma insulin ( $r = -0.482$ ,  $P = 0.011$ ) concentrations. **Discussion** The present study is the first to examine the relationship between the amount of physical activity and oxidised LDL concentrations in older adults. We demonstrated that lower concentrations of oxidised LDL were associated with higher amount of physical activity in older adults. These findings indicated that the oxidative modification of LDL may be prevented through regular physical activity. Therefore, our

findings may imply that being physically active is important to reduce the potential risk of atherosclerotic cardiovascular disease in older adults if they can maintain such status through daily life. It would be interesting to investigate whether physical activity interventions can be used to slow the progression of atherosclerosis in older adults. Reference Cakalay U, Kayali R, Uzun H. (2008). ### COMBINED IMPACT OF HEALTH BEHAVIOURS ON CARDIOVASCULAR RISK IN CHILDREN: A RANDOMIZED PROSPECTIVE STUDY

MEYER, U., BLOESCH, T., PETERHANS, E., ZAHNER, L., PUDER, J.J., SCHINDLER, C., KRIEMLER, S.

UNIVERSITY OF BASEL; UNIVERSITY HOSPITAL OF LAUSANNE

**Introduction** Factors of negative health behaviour are known to be associated with increased cardiovascular risk in children, but their combined impact on a general population of children is not well documented. We aimed therefore to quantify the combined impact of easily assessable health behaviours in randomly selected children on their cardiovascular risk four years later. **Methods** 502/540 randomly selected 6- to 13-year-old Swiss children took part in a baseline health assessment and 232 (64%) of those participated again in the same assessment four years later which included anthropometry, fasting blood samples and a health behaviour questionnaire. A cardiovascular risk score was built by averaging sex- and age-related z-scores of waist circumference, blood pressure, glucose, inverted high density lipoprotein and triglycerides. Participants scored one point for each negative health behaviour: a BMI above the 85th percentile (IOTF), less than 60 min of moderate-vigorous physical activity per day, media use of more than 120 min daily, smoking and/or overweight parents. **Results** After four years of follow up, the age-, sex-, and social class-adjusted odds ratios (95% CI) for having an unfavourable cardiovascular risk score (highest tertile of age- and sex-adjusted z-scores) for children who had no or one (n=91) compared to two (n=77), three (n=39) or three and more (n=54) risk behaviours were respectively 1.44 (0.73 to 2.85, p=ns), 2.27 (1.02 to 5.08, p=0.046) and 2.59 (1.24 to 5.40, p=0.011). **Discussion** Three or more negative health behaviours combined predicted a 2.6-fold higher risk of having an unfavourable cardiovascular risk score four years later. Thus, already in childhood, an accumulation of negative health behaviours is associated with a higher cardiovascular risk four years later in life which underlines the urge of early prevention.

### SARCOPENIC OBESITY AND PHYSICAL FITNESS IN ELDERLY PEOPLE

GÓMEZ-CABELLO, A., PEDRERO, R., DELGADO, S., HERNANDEZ, R., JUEZ, A., MATA, E., CAÑADA, D., AZNAR, S., VILLA, G., ESPINO, L., GUSI, N., GONZALEZ-GROSS, M., VICENTE-RODRÍGUEZ, G., CASAJÚS, J., ARA, I.

GENUD RESEARCH GROUP, UNIVERSITY OF ZARAGOZA, SPAIN

**Sarcopenic obesity and physical fitness in elderly people** Gómez-Cabello A1, Pedrero-Chamizo R2, Delgado S3, Hernandez R4, Juez-Bengochea A5, Mata E6, Cañada D2, Aznar S7, Villa G5, Espino L5, Gusi N3, Gonzalez-Gross M2, Vicente-Rodríguez G1, Casajús JA1, Ara I1,6 1 GENUD Research Group, University of Zaragoza, Spain 2 Department of Health and Human Performance, Universidad Politécnica de Madrid, Spain 3 Faculty of Sport Sciences, University of Extremadura, Spain 4 Unit of Sports Medicine, Cabildo of Gran Canaria, Spain 5 Institute of Biomedicine (IBIOMED), University of León, Spain 6 GENUD Toledo Research Group, University of Castilla La Mancha, Spain 7 PAFS Research Group, University of Castilla La Mancha, Spain **Introduction:** sarcopenic obesity (SO) is commonly defined as the presence of reduced muscle mass (sarcopenia) and increased fat mass (obesity) (1). Older adults with both sarcopenia and obesity have worse physical functioning than those with only one of these disorders; thus, both may act synergistically increasing the risk of disability. This study aimed to test whether any of the most widespread adapted physical fitness tests in this population group may be related to the risk of SO. **Material and methods:** 2859 subjects (671 men and 2188 women) aged 72.2±5.3 were evaluated in Spain within the framework of the elderly EXERNET multi-centre study. Anthropometric and body composition (Tanita BC 418-MA; Tokyo, Japan) measurements were performed in all subjects. Four SO groups were created based on the quintile scores for percentage of body fat and relative muscle mass; 1) normal, 2) high fat, 3) low muscle and 4) SO (2). Physical fitness was evaluated using eight different tests modified from the Senior Fitness Test and Eurofit Testing Batteries. Three different categories were created for each test based on the calculated scores. Age-adjusted logistic regression was applied to study the probability to have SO depending on the fitness level. **Results:** among the physical fitness tests studied, balance, lower-body strength and lower-body flexibility were associated to lower risk of suffering SO in the fittest men (highest tertile) by 65.5, 65.4 and 51.0%, respectively (95% CI [(0.180-0.660); (0.185-0.646); (0.275-0.872)]). In women, the risk of suffer SO was lowered by 56.2, 53.6 and 39.1% in those in the highest tertile of balance, lower-body strength and endurance, respectively (95% CI [(0.301-0.639); (0.330-0.652); (0.418-0.887)]). **Conclusion:** to preserve adequate physical fitness levels is of great importance to maintain a good health status and help to reduce the age-related functional decline. **References:** 1. ### OP-PM08 VO2max and O2 Kinetics

#### RIGHT ATRIAL PACING INCREASES MAXIMAL HEART RATE BUT DOES NOT ALTER VO2MAX OR MAXIMAL EXERCISE PERFORMANCE IN HEALTHY HUMANS

CHRISTENSEN, M.1, MUNCH, G.D.W.1, SECHER, N.H.1, SVENDSEN, J.H.2, GONZALEZ-ALONSO, J.3, MORTENSEN, S.P.1

1. THE COPENHAGEN MUSCLE RESEARCH CENTRE, RIGSHOSPITALET, DENMARK, 2. DEPARTMENT OF CARDIOLOGY, RIGSHOSPITALET, DENMARK, 3. CENTRE FOR SPORTS MEDICINE AND HUMAN PERFORMANCE, BRUNEL UNIVERSITY, GR. BR.

**INTRODUCTION:** Aerobic power (VO2max) and exercise performance is limited by a plateau or decline in cardiac output (Q) during incremental and constant load maximal exercise, but the mechanisms restricting maximal Q remain unknown. The attainment of maximal heart rate (HR) could be a factor limiting Q, but the effect of increasing maximal HR has not been investigated in humans. Therefore, the purpose of this study was to investigate the effect of HR pacing on cardiac output, VO2max and exercise performance during incremental cycling to exhaustion. **METHODS:** We measured systemic (direct Fick) and peripheral (thermodilution) hemodynamics during incremental

(25, 40, 55, 70, 85, 100% of maximal workload (WLmax)) cycling to exhaustion with (pace) and without (control) atrial pacing (15-20 beats/min higher HR than control) in 7 endurance trained cyclists (28±2 years, 181±2 cm, 72±2 kg, 66±1 mlO<sub>2</sub>/min/kg). Data were analyzed by repeated measures two-way ANOVA and Tukey's honestly significant difference (HSD) post hoc procedure. RESULTS: Atrial pacing increased HR during submaximal cycling and peak HR by 16±2 beats/min (HRmax 185±1 and 201±6 beats/min in control and pace, respectively) (P<0.05). However, cardiac output and leg blood flow (LBF) increased similarly in both trials and reached the same peak Q (23.1±0.9 and 24.8±1.4 l/min in control and pace, respectively), LBF (9.7±0.1 and 9.7±0.2 l/min, respectively), VO<sub>2</sub> (4.8±0.1 and 4.7±0.1 l/min, respectively) and exercise performance time (11:33±0.01 and 11:15±0.01 min, respectively). Furthermore, there was no difference in plasma norepinephrine or epinephrine levels between conditions. In both trials, Q increased linearly until 55% of WLmax but then levelled off in parallel to a drop in stroke volume and an increase in central venous, pulmonary arterial and mean arterial pressures (P<0.05). DISCUSSION: The present results demonstrate for the first time that healthy humans can achieve a higher maximal HR during atrial pacing compared to control conditions and that this increase in HR does not alter peak cardiac output, VO<sub>2</sub>max or maximal exercise performance. Supported by Team Denmark

### CONVENTIONAL TESTING METHODS PRODUCE SUB-MAXIMAL VALUES OF MAXIMUM OXYGEN CONSUMPTION .

BELTRAMI, F.G.1, FROYD, C.1, MAUGER, A.R.2, METCALFE, A.2, MARINO, F.3, NOAKES, T.D.1

1: UCT/CAPE TOWN, SOUTH AFRICA; 2: IBEDS, UNITED KINGDOM; 3: ICSU, AUSTRALIA

Background This study used a novel protocol to test the hypothesis that a plateau in oxygen consumption (VO<sub>2</sub>max) during incremental exercise testing to exhaustion represents the maximal capacity of the cardiovascular system. Methods Twenty six subjects (23 male, 3 female, age 29.5 ± 10.0 years, body mass 73.7 ± 9.8 kg, height 177 ± 6 cm) were randomly divided into two groups matched for their initial VO<sub>2</sub>max. On separate days, the reverse group performed an incremental uphill running test (INC1) followed 15 minutes later by a verification phase test (Day 1), a decremental test (DEC) (Day 2) and a final incremental test (INCF) (Day 3). The decremental test started at 1 km.h<sup>-1</sup> higher than the maximal running speed achieved during INC1 and speed was reduced progressively throughout the test. Before the trials all participants were familiarized with both the incremental and decremental test. The control group performed incremental tests on the same 3 days that the reverse group was tested. Results All but one subject in each group reached a plateau during INC1. VO<sub>2</sub>max remained within 0.6 ml.kg<sup>-1</sup>.min<sup>-1</sup> over the trials for the control group (p = 0.93), but was 4.4% higher during DEC compared to INC1 (63.9 ± 3.8 vs. 61.2 ± 4.8 ml.kg<sup>-1</sup>.min<sup>-1</sup> respectively, p = 0.004) in the reverse group. VO<sub>2</sub>max remained significantly higher during INCF (63.6 ± 3.68 ml.kg<sup>-1</sup>.min<sup>-1</sup>, p = 0.01) in comparison to INC1 for the reverse group, despite an unchanged exercise time. The difference in VO<sub>2</sub>max between INC1 and DEC was on average 2.7 ± 3.2 ml.kg<sup>-1</sup>.min<sup>-1</sup> (~200 ml.min<sup>-1</sup>), 60% higher than the upper threshold for a VO<sub>2</sub> plateau during INC1 (1.7 ml.kg<sup>-1</sup>.min<sup>-1</sup>, 123 ml.min<sup>-1</sup>). The difference in VO<sub>2</sub>max was also beyond the upper limit of the typical error of measurement in VO<sub>2</sub>max calculated for the control group (1.6 ml.kg<sup>-1</sup>.min<sup>-1</sup>, 95% CI 1.3 to 2.1 ml.kg<sup>-1</sup>.min<sup>-1</sup>). The higher values in VO<sub>2</sub>max during the DEC protocol were achieved even though the participants were running at 1.9 km.h<sup>-1</sup> slower during DEC (14.3 ± 1.1 vs. 16.2 ± 0.9 km.h<sup>-1</sup> for DEC and INC1 respectively, p=0.0001). Peak ventilation rate, heart rate, breathing frequency and respiratory exchange ratio were not different between the trials for any of the groups, although peak ventilation rate in the control group fell between INC1 and INCF. Conclusion These findings disprove the concept that a plateau in oxygen consumption during an incremental exercise test represents a systemic limitation to oxygen use. The reasons for a higher VO<sub>2</sub> during the final incremental test following the decremental test remain unclear but suggest the presence of an acute adaptive response probably regulated in the central nervous system.

### LINEARITY OF V'O<sub>2</sub>-KINETICS DURING MODERATE PRBS EXERCISE TESTING

DRESCHER, U., STEEGMANN, A., HOFFMANN, U.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction Static and dynamic linearity can be a prerequisite for further analysis of oxygen uptake kinetics. Specifically, the combinations of on- and off-step responses which are part of the pseudo random binary sequence-testing (PRBS) rely on this assumption. However, some instances might be in contradiction to the dynamic linearity: 1. In the transition phase the venous return is influenced by the venous blood volume between exercising tissues and lungs, the perfusion rate of the exercising muscles and cardiac output (CO). As a consequence, in the whole transition respiratory V'O<sub>2</sub> (V'O<sub>2</sub>R) is a distorted version of muscular V'O<sub>2</sub> (V'O<sub>2</sub>M). A traditional used method is an exclusion of the first 20s in the transition phase, but neglects the complex interactions of the cardio-vascular parameters. 2. Differences in on- and off-step responses of V'O<sub>2</sub>M are also in contrast to the assumption of dynamic linearity. Frequently reported are asymmetries detected by monoexponential fitting for V'O<sub>2</sub>R may indicate asymmetries in V'O<sub>2</sub>M (Rossiter et al., 2002). The aim of this study is to analyze the assessed V'O<sub>2</sub>R for linearity. Methods 17 volunteers (age: 28 ± 6 years; height: 174 ± 8 cm; weight: 71 ± 12 kg; V'O<sub>2</sub>peak: 3.8 ± 1.0 l•min<sup>-1</sup>) were subjected to two moderate PRBS workload (WL) changes (min: 30 W, max: 80 W, mean: 53.3 W; duration per sequence: 300s), 2 constant WL phases (30 W, 80 W, 200s). Gas exchange was assessed breath-by-breath (ZAN 680, ZAN Messgeräte, Oberthulba, Germany). Averages for 30 W and 80 W, respectively, were calculated from the last 30s of the constant phases for each subject. Expected V'O<sub>2</sub> (V'O<sub>2</sub>(53.3W)) for 53.3 W were interpolated and compared with the averages of the two PRBS separately (V'O<sub>2</sub>(PRBS1), V'O<sub>2</sub>(PRBS2)). ANOVA for repeated measurements was applied. Results V'O<sub>2</sub>(PRBS1) was calculated as 1.087 ± 0.129 l•min<sup>-1</sup>, V'O<sub>2</sub>(PRBS2) as 1.097 ± 0.125 l•min<sup>-1</sup> and V'O<sub>2</sub>(53.3W) as 1.094 ± 0.127 l•min<sup>-1</sup>. ANOVA showed no significant differences (p>0.05; n=17). Discussion The results are in line with the assumptions of static linearity of V'O<sub>2</sub>R. This is in contradiction to reported on-off asymmetries for V'O<sub>2</sub>R. If on-kinetics faster than off-kinetics this would result in higher averages in the PRBS intervals. The influence from CO dynamics and invalidity of monoexponential fitting can explain this result. For further analysis a two compartment model representing the exercising and non-exercising part of the body, considering the cardio dynamic influences, can be applied to estimate V'O<sub>2</sub>M assuming dynamic and static linearity in the transition phases. The study was funded by the DLR (Deutsches Zentrum für Luft- und Raumfahrt), Germany (FKZ 50WB0726). References Rossiter, HB, Ward, SA, Kowalchuk, JM, Howe, FA, Griffiths, JR and Whipp, BJ (2002). **RAT MODELS SELECTIVELY BRED TO DIFFER FOR MAXIMAL AEROBIC CAPACITY DIVIDE FOR AGING AND LONGEVITY**

KOCH, L.1, BRITTON, S.1, KEMI, O.2, LENG, S.3, QI, N.1, BIJMA, P.4, GILLIGAN, L.1, WILKINSON, J.1, WISLOFF, H.5, ABADIR, P.3, VAN GREVENHOF, I.4, SMITH, G.2, BURANT, C.1, ELLINGSEN, O.6, WISLOFF, U.6

UNIVERSITY OF MICHIGAN (1) UNIVERSITY OF GLASGOW (2) JOHNS HOPKINS UNIVERSITY (3) WAGENINGEN UNIVERSITY (4) NATIONAL VETERINARY INSTITUTE, OSLO (5) NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY (6)

Rationale: Low aerobic exercise capacity is a powerful predictor of premature morbidity and mortality. For aged populations, poor performance on treadmill or extended walking tests indicates closer proximity to future health declines. The underlying mechanisms connecting aerobic capacity to survivability, however, are difficult to explore in humans. Objectives: To develop an animal model system that: a) prospectively tests whether aerobic energy capacity associates with complex disease and longevity (aerobic hypothesis) and b) can serve as a more accurate experimental representation for translational studies (1). Methods: Laboratory rats of widely diverse genetic backgrounds (N:NIH stock) were selectively bred across 20 generations (n=7,342 rats) for low or high intrinsic (inborn) treadmill running capacity (2). Cohorts of male and female rats derived from generations 14, 15 and 17 were followed for survivability and evaluated for age-related declines in cardiovascular fitness including maximal oxygen uptake (VO<sub>2</sub>max), myocardial function, endurance performance, and change in body mass. Results: Median lifespan for high exercise capacity rats was 28-45% longer than low capacity rats (hazard ratio, 0.06; P<.001). VO<sub>2</sub>max, measured across adulthood was a reliable predictor of lifespan (P<.001). During progression from adult to old age, left ventricular cardiomyocyte morphology, contractility, and intracellular Ca<sup>2+</sup> handling were less compromised in rats bred for high aerobic capacity. Physical activity levels, energy expenditure (VO<sub>2</sub>), and lean body mass were all better sustained with age in rats bred for high aerobic capacity. Conclusions: These data from a contrasting rat model system provide strong evidence that genetic segregation for aerobic exercise capacity can be linked with longevity. **HEART RATE AND OXYGEN UPTAKE KINETICS DURING INTERMITTENT APNEIC EXERCISE**

COTUK, B.1, SAHIN, O.1, ATES, O.2, BICER, B.1, PELVAN, O.1, TOPSAKAL, N.1, AKTAS, S.2

1: MARMARA UNIVERSITY (ISTANBUL, TURKEY), 2: ISTANBUL UNIVERSITY (ISTANBUL, TURKEY)

Introduction: Underwater hockey is a sport which is performed by repeated apneic swimming. Such combination of apnea and intermittent exercise may pose specific regulatory demands on oxygen delivery and uptake. Therefore we investigated the effects of repeated apneas on heart rate response patterns and oxygen uptake kinetics during intermittent exercise while increasing power output. Methods: 8 elite male underwater hockey players (VO<sub>2</sub>max=3.8±0.5 l/min) performed five dry apneas. The first apnea was performed at rest, and then four apneas were performed while exercising on a bicycle ergometer. Power output was increased from 25 W to 175 W by 50 W increments for each apneic exercise section which lasted 45 s. Recovery between the apneic exercises lasted two minutes. The athletes were connected to a spiro-ergometer (ZANR) and heart rate was collected on a beat to beat basis by telemetric device (Polar S810iR). Results: Two basic response patterns for heart rate were observed during apneic exercise. Either a monotonic heart rate decrease developed during the entire exercise, or a heart rate increase in the beginning changed to a bradycardia towards the end of the exercise (biphasic response pattern). The increase of power output elevated heart rate during the entire exercise and prolonged the tachycardia, but did not affect the basic response pattern. The total number of heart beats during the apneas increased only slightly (rest 61 beats, 25W 73 beats, 75W 76 beats, 125W 77 beats, and 175W 78 beats). Heart rate and oxygen uptake were elevated during the first minute of the recovery period and returned to baseline levels in the second minute. These post-exercise increases in heart rate and oxygen uptake were correlated positively with power output of the prior apneic exercise. Discussion: During apneic exercise the physiological conflict between "exercise-tachycardia" and "apnea-bradycardia" is predominantly solved in favor of the oxygen conserving heart rate decrease. But increase of power output counteracts this mechanism by an individually varying degree. During the recovery period after the apneic exercise, oxygen delivery and uptake increases in order to match prior metabolic costs.

**PRECONDITIONING EFFECT OF REPEATED EXERCISE BOUTS ON O<sub>2</sub> UPTAKE KINETICS**

TARPERI, C., BARALDO, A., ZARANTONELLO, A., CEVESE, A.

UNIVERSITY OF VERONA

Introduction Short distance repetition of equal intensity bouts of aerobic exercise generally does not change the physiological response by time or fatigue factors. It has been demonstrated, however, that a short bout of heavy exercise may speed up oxygen consumption kinetics (V'O<sub>2</sub>kin) at the onset of a second aerobic exercise (preconditioning effect, PE). PE is effective only for high intensity exercise in young physically fit subjects, while it works also for moderate intensity exercise in elderly individuals. We speculated that if PE effectiveness is somehow inversely related to fitness, even a bout of moderate intensity exercise might exert a PE in individuals with different kinds of pathologies. Methods We reviewed the results of 119 subjects who performed two bouts of 6 min cycle ergometer exercise, separated by 6 min sitting rest, while connected to a metabolimeter for breath by breath recording of respiratory variables. The subjects pedaled at 60-70 strokes/min against a load below the individual first ventilatory threshold previously determined. The subjects were subdivided in 5 groups: 40 healthy young controls (HYS, 26±5yy, 173±8cm, 69±11kg), 27 Chronic Heart Failure (CHF, 66±6yy, 172±7cm, 77±12kg), 12 Type 2 Diabetic (DM2, 58±6yy, 169±10cm, 77±12kg), 15 medically treated hypertensive (HYP, 68±5yy, 171±4cm, 78±9kg), 25 healthy elderly (HES, 66±5yy, 171±8cm, 79±9Kg). Bxb oxygen values (V'O<sub>2</sub>bxb) were used to calculate oxygen deficit (defO<sub>2</sub>) as the difference between theoretical and real V'O<sub>2</sub> (defO<sub>2</sub>=(mean steady state V'O<sub>2</sub>\*360s - 1Σ360V'O<sub>2</sub>bxb)). The mean response time (MRT, in seconds) was calculated as the ratio between defO<sub>2</sub> and V'O<sub>2</sub>ss. The same method was applied to bxb V'CO<sub>2</sub>, Tidal Volume VT, and Ventilation VE. Results Data are presented as mean±SD. Two way ANOVA was used to detect significant differences among groups and between the first and the second trial of each group (P<0.05). We did not find statistically significant differences in MRT of any variable in HYS, DM2, HYP, or HES, either on the first or on the second trial. The CHF group, to the contrary, in the first trial had MRTV'O<sub>2</sub> (44.4 ± 11.3) significantly slower than that of the other groups (HYS 29.1 ± 13.1; DM2 29.3 ± 12.7; HES 25.9 ± 14.8; HYP 18.5 ± 8.4). In the second trial the CHF group showed a significant PE effect both on metabolic (MRTV'O<sub>2</sub> -11.5s, -19%; MRTV'CO<sub>2</sub> -12.2s, -16%) and on ventilatory (MRTVT -13.3s -39%; MRTVE -14.3s, -20%) responses. Discussion Thus, the preconditioning exercise bout does not always need to be of high intensity in order to speed up V'O<sub>2</sub>kin of the following moderate intensity exercise. This effect, however, requires a reduced cardiac function, indicating that the conditioning effect of a fully aerobic exercise regards oxygen transport mechanisms.

### OP-PM12 Training and Testing: Team Sports

#### USE OF SESSION-RPE FOR THE EVALUATION OF THE YOUTH WATER POLO TRAINING LOAD

LUPO, C., CONDELLO, G., CAPRANICA, L., TESSITORE, A.  
UNIVERSITY OF ROME

**Introduction** The assessment of internal training load (TL) using Borg's Category Ratio-10 (CR-10) RPE scale as a measure of exercise intensity has been demonstrated to provide valuable information (Foster, 2001), also in team sports with both adult and young players (Impellizzeri et al., 2004). Nevertheless, no studies investigated the use of this method during water polo trainings. Thus, the aim of this study was to evaluate youth water polo trainings, showing the correspondent level of reliability of session-RPE method. **Methods** Ten male youth water polo players (age=15.6±0.5 yrs; height=179.6±5.9 cm; weight=72.7±7.8 kg) took part in the study. Session-RPE (CR-10 Borg scale), heart rate (HR) monitor (Polar Team System) and duration were recorded for 60 individuals training sessions. The TL for each session was calculated multiplying the training duration in minutes by the mean training intensity (RPE score). The HR-based method proposed by Edwards (1993) for determining internal TL was used as criterion measure of internal TL in this study. An exercise score for each training unit was calculated by multiplying the accumulated duration in each HR zone by a coefficient allocated to each zone (50-60%HRmax=1, 60-70%HRmax=2, 70-80%HRmax=3, 80-90%HRmax=4, and 90-100%HRmax=5) and then summing the results. Individuals HRmax were calculated with the formula  $(220 - \text{age})$ . Pearson's correlation coefficient and Cohen's effect size (ES) was used to evaluate the relationship between the HR-based method and session-RPE scores. **Results** The HR frequency was meanly reported as follows: <50%HRmax=6±9%, 50-60%HRmax=24±17%, 60-70%HRmax=31±12%, 70-80%HRmax=28±14%, 80-90%HRmax=10±13%, 90-100%HRmax=1±3%. Correlations between the HR-based method and session-RPE scores were statistically significant (from  $r=0.46$  to  $r=0.65$ ,  $p<0.0001$ ,  $ES=0.6$ ). **Discussion** According to Impellizzeri et al. (2004), the present results confirmed the satisfactory correlation between the HR-based method and session-RPE scores, highlighting the latter as an easy and reliable method to evaluate the training load in youth water polo. **References** Foster C, Florhaug JA, Gottschall L, Hrovatin LA, Parker S, Doleshal P, Dodge C (2001), J. #### PHYSICAL DEMANDS IN MALE ELITE TEAM HANDBALL

MICHALSIK, L.B.  
UNIVERSITY OF AARHUS, AARHUS, DENMARK

The present study examined the physical demands placed on male elite Team Handball (TH) players in relation to playing position. Male elite TH were closely observed and monitored over a six season time span. Each player (wing players: WP, circle runners: CR, backs: B) was evaluated during match play by use of video recording and subsequent time-motion and technical analysis. In addition, physiological measurements during match play, physical testing and anthropometric measurements were carried out. The mean body height (BH), body mass (BM) and age in best the Danish male Handball League in total were 189.6±5.8 cm, 91.7±7.5 kg and 26.1±3.9 years, respectively. VO2-max was in average 5.0±0.7 l O2/min corresponding to 55.2±4.1 ml O2/min/kg. The mean total running distance in the Yo-Yo intermittent recovery test (level 2, IR-2 test) was 895±184 m. The hardest shot was the set shot with three steps run-up (in average 92.8±5.3 km/hour). The mean total distance covered (TDC) per match was 3627±568 m with a mean total effective playing time (TPT) of 53:51±5:52 min:sec, and the mean speed was 6.40±1.01 km/hour. High intensity work (HIW) only constituted 1.7±0.9 % of TPT per match corresponding to 7.9±4.9 % of TDC. A game consisted in average of 1782±313 activity changes with an average of 53±14 high intensity runs per match. The amount of HIW was lower ( $p<0.05$ ) in the second half (130.4±77.2 m) than in the first half (155.3±92.6 m) corresponding to a mean decrease of 16.0 %. The players made in average in attack 6.0±5.2 fast breaks, received 34.5±24.7 checkings in total and gave 5.8±3.6 hard checkings and did 3.7±3.5 blocks and 3.9±3.0 claspings in the defence. The mean relative work load during match play was 70.9±6.0 % of VO2-max. Mean post match blood lactate concentration was 4.8±1.9 mM (range: 2.8 to 10.8 mM). The mean weight loss was 0.8±0.4 kg pr. match. WP had less BH and BM (184.9±5.7 cm, 84.5±5.8 kg,  $p<0.001$ ) compared to B (191.9±5.4 cm, 94.7±7.1 kg) and especially CR (194.8±3.6 cm, 99.4±6.2 kg). In the IR-2 test, WP (975±123 m) ran longer ( $p<0.05$ ) than B (897±108 m) and CR (827±264 m). Both B (3765±532 m) and WP (3641±601 m) performed a greater ( $p<0.05$ ) TDC per match than CR (3295±495 m). In addition, WP performed more HIW (10.9±5.7 % of TDC) than both CR (8.5±4.3 %,  $p<0.05$ ) and B (6.2±3.2 %,  $p<0.01$ ). Both in offence and in defence, WP received and gave less checkings in total per match (14.9±3.7, 19.5±8.9) than both B (29.8±16.1, 31.2±12.2,  $p<0.05$ ) and especially CR (70.5±23.7,  $p<0.001$ , 40.3±14.4,  $p<0.01$ ). In conclusion, male elite TH is a physically demanding intermittent game, which in particular places high demands on the anaerobic and to a lesser extent on the aerobic muscle energy production. There were indications that temporary fatigue may occur. Physical demands differed between playing positions, and anthropometry seems to have a vital influence on the playing performance on the various playing positions.

#### CHANGES IN BODY COMPOSITION AND ENERGY EXPENDITURE OVER THE SEASON IN ELITE JUNIOR BASKETBALL PLAYERS: IS THERE A LINK?

SILVA, A.M., SANTOS, D.A., MATIAS, C.N., ROCHA, P.M., SARDINHA, L.B.  
EXERCISE AND HEALTH LABORATORY, FACULTY OF HUMAN KINETICS, TECHNICAL UNIVERSITY OF LISBON (LISBOA, PORTUGAL)

**Introduction** The effect of an entire season in energy expenditure, specifically at rest (REE), may be determined by changes that occur in body composition. Therefore, the purpose of this study was twofold: to compare changes in body composition, REE, and total energy expenditure (TEE) over a season and to examine the contribution of changes in total and regional fat (FM) and fat-free mass (FFM) on REE in junior elite basketball players. **Methods** At the beginning of the pre-season and at the end of the competitive period, measures of total and regional FM, FFM, lean-soft tissue (LST), and bone mineral content (BMC) estimated by dual-energy x-ray absorptiometry and REE by indirect calorimetry were obtained in 8 males (Height: 1.75±0.05m; Weight: 77.7±6.6kg; %FM: 12.7±1.7%) and 10 females (Height: 1.94±0.05m; Weight: 63.5±7.2kg; %FM: 23.0±3.2%) of the Portuguese basketball team (16-17 yrs). Using doubly labeled water, TEE was assessed in a subsample of 5 males and 5 females. Activity energy expenditure (AEE) was calculated as the difference between TEE and REE while physical activity level (PAL) was determined as the ratio between TEE to REE. Changes were expressed as a percentage from the baseline values. **Results** Throughout the season, REE and TEE increased by 15.3±15.2% ( $p=0.001$ ) and by 13.1±12.5% ( $p=0.008$ ), respective-

ly, while no significant changes ( $p>0.05$ ) were observed in AEE ( $14.0\pm 25.5\%$ ) and PAL ( $-1.1\pm 17.1\%$ ). Increases in FFM were observed ( $5.1\pm 4.8\%$ ,  $p<0.001$ ) but no significant changes were found in FM ( $-1.0\pm 7.8\%$ ). A raise ( $p<0.001$ ) in total BMC ( $5.1\pm 4.8\%$ ) and regional LST of the arms ( $7.2\pm 6.5\%$ ), legs ( $4.2\pm 3.9\%$ ), and trunk ( $3.6\pm 3.5\%$ ) was observed while no changes ( $p>0.05$ ) were found for regional fat mass (arms:  $-3.9\pm 12.3\%$ ; legs:  $-1.8\pm 10.4\%$ ; trunk:  $1.0\pm 12.8\%$ ). The REE to FFM ratio significantly increased by  $11.1\pm 13.7\%$  ( $p=0.003$ ). Using multiple regression analysis, FFM changes explained 22.3% of the total variance in REE alteration ( $\beta=3.257$ ;  $p=0.049$ ), controlling for the effect of gender. From the remaining body composition variables, only legs LST variation explained 24.5% of the changes observed in REE ( $\beta=1.939$ ;  $p=0.044$ ), after adjusting for gender. Discussion Over the season, TEE, REE, and a higher resting metabolic rate per FFM units were observed and, as expected, the raise in REE was explained by an increase in FFM. Furthermore, these findings highlight the contribution of appendicular LST, specifically located at the lower limbs area, as a key component for the higher REE occurred over the season in elite junior basketball players.

### REACTIVE STRENGTH VS POWER: THE BEST PREDICTOR OF SPEED IN ELITE U'20 SUPER LEAGUE RUGBY PLAYERS?

HARPER, D., HOBBS, S., MOORE, J.

*RUNSHAW COLLEGE (UNIVERSITY OF CENTRAL LANCES)*

Introduction There is a paucity of research that as investigated what strength characteristics best transfer to the high intensity sprint movements performed by elite rugby-league players (Baker & Nance, 1999; Cronin & Hansen, 2005; Harris et al., 2008). Therefore, the aim of this study was to identify relationships between reactive strength and power and measures of speed, change of direction (COD) ability and reactive agility in elite rugby-league players. Method Sixteen Super League rugby-league players (age,  $19.7 \pm 0.8$  years, weight  $88.5 \pm 12.0$  kg, height  $177.3 \pm 6.1$  m) participated in the study. Tests included: sprint time (5-m, 10-m, 20-m and 30-m); COD ability (L-run); reactive agility (cut test); loaded (25 and 50% body weight) and unloaded vertical jump (VJ); squat jump (SJ) and reactive strength via a vertical rebound jump (10 to 5 repeated jump test) performed over a series of 10 repetitions with ground contact time of less than 0.25s. All tests were measured using Smart-speed/jump (Fusion Sport, Australia). Results The 5-m, 10-m, 20-m and 30-m sprint times were all significantly correlated ( $r=0.80$  to  $0.95$ ). Significant relationships ( $r=-0.54$ ) were found with 5-m speed and unloaded VJ height. In addition a significant relationship ( $r=-0.54$ ) was found between 30-m speed and loaded VJ (50%BW). The reactive agility (cut test) time had a significant relationship with SJ height ( $r=0.58$ ). The single best predictor of change of direction speed was SJ height ( $r=-0.75$ ). Squat jump height had significant relationships with all VJ heights ( $r=0.69$  to  $0.87$ ). Reactive strength had moderate to large relationships ( $r=-0.34$  to  $-0.51$ ) with all sprint measures and a large relationship with COD speed ( $r=-0.49$ ). Discussion Reactive strength had moderate to large relationships with all sprint distances, accounting for up to 26% of sprint performance. The lack of relationship between reactive strength and sprint performance however is not surprising. The running mechanics of rugby league players is characterised by a more slouched upper body posture with significant forward lean. Interestingly, it was the measures of concentric only (SJ) performance that resulted in the highest correlations with all speed measures. References Baker, D. G. & Nance, S. (1999). The relation between running speed and measures of strength and power in professional rugby league players. *Journal of Strength & Cond. Res.* 13, (3), 187-304. Cronin, J. B. & Hansen, K. R. (2005). ### THE COMPARISON OF SOME ANTHROPOMETRIC, MOTOR AND PHYSICAL FITNESS FEATURES OF IRAN AND PAKISTAN NATIONAL KARATE PLAYERS

TARVERDIZADEH, B.

*ISLAMIC AZAD UNIVERSITY, BUSHEHR BRANCH*

The purpose of this research is the definition and the comparison of some anthropometric and the motor and physical fitness features of Iran and Pakistan National karate players. The statistic community of this research consists of the karate players who were invited in Iran and Pakistan National teams. Statistic samples of this research are 20 people which consist of 10 karate players who have invited in national team, and 10 karate players from Pakistan national team who took part voluntarily in this research at the same condition. Anthropometric variables of this research follow as; age, weight, size, hand length. lower part of the body, percent fat, body fat level, body net weight (with no fat), BMI, and motor fitness variables are; agility (live lines) SEMO, 4\*9 meter running, long jump, high jump, reaction, 45 meter speed running, balance, sit-up. Undoubtedly, other variables like, the age of starting activity, back ground in activity and being in a national team was compared, too. In analyzing data, with explaining team, a separate T statistical method made by using of SPSS software in a meaningful level ( $P<0/05$ ). According to the results, there is a meaningful difference in variables like, the age of starting activity, the background in membership, players age, percent fat, reaction and sit-up. of course, there was not a meaningful difference in other variables such as background in activity. Weight, size, the lower part of the body, hand length, fat level, body net weight, BMI, agility with both test, 45 meter speed running, balance, long jump and high jump. According to these results, in contrast with anthropometric and motor fitness of Iranian and Pakistani karate players. There is a difference in some variables, and Iranian karateists were in an appropriate level than Pakistani karateists in some variables. It can be possible reason for difference in world classification of these two teams.

#### AEROBIC FITNESS AND PHYSIOLOGICAL PROFILE OF TRAINING AND MATCH PLAY IN 100 VETERAN FOOTBALL PLAYERS

FAUDE, O., WEGMANN, M., STEFFEN, A., PÜTZ, K., WÜRTZ, W., AUS DER FÜNTEN, K., SUCH, U., MEYER, T.

*SAARLAND UNIVERSITY*

Introduction Several recent studies reported positive health and fitness effects of playing football in different populations (Krustrup et al., 2010). Most studies were well-controlled with regular supervised training. To date, scientific data with regard to fitness and health status

in subjects playing lifelong football in a real life setting are scarce. The present analysis aimed at describing the aerobic fitness as well as training and match play characteristics in veteran football players. Methods 100 veteran football players aged between 40 and 63 ( $47 \pm 5$ ) yrs underwent a complete medical check up incl. training history and a graded cycle ergometer test to determine maximal power output (Pmax) and peak oxygen uptake (VO<sub>2</sub>peak). In addition, a multi-stage graded field test was carried out to determine endurance capacity (maximal lactate steady state, MLSS (Stegmann et al., 1981) and maximal running velocity). In 54 players, heart rate (HR) and blood lactate concentrations (bLa) were collected during typical training sessions (90 min) and match play (70 min). Results Subjects played football for an average of  $36 \pm 8$  yrs. Training was scheduled on average one time per week and mean match frequency was  $27 \pm 8$  matches per year. Pmax was  $2.8 \pm 0.6$  W/kg and VO<sub>2</sub>peak  $40.1 \pm 7.3$  ml/(min\*kg). Field testing revealed a mean running velocity at MLSS of  $10.6 \pm 1.3$  km/h and at maximum of  $14.5 \pm 1.6$  km/h. Maximal HR and bLa were  $181 \pm 9$  min<sup>-1</sup> and  $11.3 \pm 2.3$  mmol/l. HR during training was  $144 \pm 13$  (80% HRmax) on average and  $177 \pm 13$  min<sup>-1</sup> at peak (98% HRmax). During competition mean and maximal HR were  $140 \pm 16$  (77% HRmax) and  $180 \pm 13$  min<sup>-1</sup> (99% HRmax). Maximal and average bLa during training were  $5.7 \pm 2.6$  mmol/l and  $4.8 \pm 2.2$  mmol/l and during competition  $6.0 \pm 2.5$  mmol/l and  $4.8 \pm 2.1$  mmol/l, respectively. Intensity was above 80% HRmax for about 43% of playing time. There were no significant differences between training and matches for HR and bLa recordings ( $p > 0.28$ ). Discussion Aerobic fitness of German veteran soccer players is comparable to untrained young men and better than in the general population. Intensity in training and matches was slightly lower than recently reported in middle-aged men (Randers et al., 2010). Nonetheless, playing football regularly for a long time in a real life setting seems to induce beneficial fitness adaptations. References Krstrup P, Dvorak J, Junge A, et al. ### MUSCULAR STRENGTH IMBALANCE INFLUENCES FATIGUE AFTER SOCCER SPECIFIC INTERMITTENT PROTOCOL

CAMARDA, S.R.A., DENADAI, B.S.

UNESP

Introduction Epidemiological studies have suggested that muscular strength imbalance and fatigue might increase the susceptibility of a player to injury, especially during the last quarter of the match (Croisier et al., 2008). This study aimed to investigate the muscular strength imbalance dependence of the effect of fatigue induced by an exhaustive laboratory-based soccer-specific exercise on conventional (Hcon:Qcon) and functional (Hecc:Qcon) ratios of soccer players. Methods Nineteen male professional soccer players were assigned to two groups: players with (UNBG - N=8, age:  $23.2 \pm 3.8$  years, VO<sub>2</sub>max:  $55.2 \pm 3.5$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) and without muscular imbalance (BG - N=11, age:  $23.1 \pm 3.1$  years, VO<sub>2</sub>max:  $54.9 \pm 3.7$  ml.kg<sup>-1</sup>.min<sup>-1</sup>). The players were allocated into one of two groups in accordance to their personal Hcon:Qcon (BG = Hcon:Qcon > 0.60; UNBG = Hcon:Qcon < 0.60). Before (Pre) and after (Post) an exhaustive laboratory-based soccer-specific exercise (Drust et al., 2000) each player performed maximal concentric contractions for knee extensors (KEcon) and flexors (KFcon) at 60°.s<sup>-1</sup> and 180°.s<sup>-1</sup>. Furthermore, maximal eccentric contractions for knee flexors (KFecc) at 180°.s<sup>-1</sup> were assessed. Results KEcon and KFcon at 60°.s<sup>-1</sup> were significantly reduced after exercise for both groups. However, KFecc at 180°.s<sup>-1</sup> was significantly reduced only in BG. Hcon:Qcon and Hecc:Qcon were significantly reduced after exercise in BG (0.65 vs. 0.62; 1.38 vs. 1.20, respectively), but not in UNBG (0.55 vs. 0.54; 1.19 vs. 1.13, respectively). Discussion The principal original finding of this investigation was that the effect of fatigue induced by an exhaustive laboratory-based soccer-specific exercise on Hcon:Qcon and Hecc:Qcon in the dominant leg of professional soccer players is dependent on muscular strength balance. Specifically, consistent with previous studies (Delestrat et al., 2010), both Hcon:Qcon and Hecc:Qcon of BG were reduced after exercise. However, UNBG did not present reduction on Hcon:Qcon and Hecc:Qcon after exercise. Thus, epidemiologic observations of increased hamstrings strain incidence during the latter stages of match play (Hawkins et al., 2001) do not seem to be explained by further impairment of Hcon:Qcon and Hecc:Qcon after exercise in UNBG. ### TIME MOTION ANALYSIS AND PHYSIOLOGICAL DEMANDS OF PLAYMAKER IN SEMI PROFESIONAL FEMALE HANDBALL

ONUSAITYTE, G., SKARBALIUS, A.

LITHUANIAN ACADEMY OF PHYSICAL EDUCATION

Introduction Athletes' movements patterns combined with heart rate (HR) responses and sources of muscular energy are classically used to provide insight into the physiological demands of team sports (Rannou et al., 2001; Coutts et al., 2003). The aim of the research was to determine movements and physiological demands of semi professional performance playmaker during official matches in handball. Methods The analysis of movement and physiological demands of player was done using the "Suunto t6" running pack (Finland) in a official matches (n=7) of the Lithuanian female championship in 2010/2011. VO<sub>2</sub>max, HRmax, aerobic and anaerobic thresholds were determined by means of an incremental treadmill test with spirometry until exhaustion in the beginning of the season. Energy resources, EPOC, ventilation, VO<sub>2</sub>max demands were estimated on the basis of HR indices. Results The mean distance covered were  $4.96 \pm 0.68$  km, velocitymax –  $12.2$  km/h<sup>-1</sup>. The indices of HR were  $175.7 \pm 7.2$ , HRmax –  $193$  bpm, EPOC –  $237 \pm 51$  ml/kg<sup>-1</sup>, ventilation  $77.8 \pm 2.3$  l/min<sup>-1</sup>; VO<sub>2</sub>max –  $44.5 \pm 5.5$  ml/kg<sup>-1</sup>.min<sup>-1</sup>. Demands of energy resources were used in such a way: under aerobic threshold – 10.3 %, between aerobic and anaerobic threshold – 81.7 %, and over anaerobic threshold – 8 %. Discussion The mean HR of player in matches were higher as the Manchado and Platen (2008) estimated in female handball (162 beats.min<sup>-1</sup>). The HRmax of playmaker was the same as the Manchado and Platen (2008) estimated in modern handball, but the mean of VO<sub>2</sub>max less. Mean run distance during the match was less as Manchado and Platen (2008) estimated in modern handball. We conclude (Gorostiaga et al., 2006) that less distance covered, higher HR, but less VO<sub>2</sub>max, demonstrate not enough fitness of semi-professional subject and for practical needs may have good information for designing training programme. ## A HIGH AND HOMOGENOUS LEVEL OF AEROBIC ENDURANCE IN YOUNG ELITE SOCCER PLAYERS

STERZING, B.1, SCHUSTER, R.1, SIMON, P.1, STRIEGEL, H.2

JGU, MAINZ/GERMANY (1), UKT, TÜBINGEN/GERMANY(2)

**Introduction** In modern football, players on any position have to meet widespread requirements in technical, tactical, cognitive and physical condition skills. High endurance performance belongs to one of the elementary abilities. But at which point in time it is most suitable for young soccer players to improve aerobic capacity? Here we therefore investigated a large cohort of junior soccer players for differences between age groups and for intra-individual improvements of aerobic capacity over time. **Methods** We assessed the data of 832 field tests of 161 German premier division players (PDP) in the age groups U16 U17, U19 and U23. Velocity (km/h) at individual anaerobic threshold (IAT) and at 4mmol/l was determined by blood lactate measurement in an incremental running test with an increase of velocity of 2 km/h every 3min until exhaustion. Intra-individual change in the thresholds was determined for all players that were assessed in at least three consecutive seasons (n=50). **Results** Aerobic endurance measured by IAT differed over all age groups significantly ( $p=0.038$ ) between pre-season 14.0 km/h (95% CI: 14.1-14.0) to in season 14.2 km/h (95% CI: 14.3-14.2), while no significant difference ( $p=0.12$ ) was obtained for the 4mmol/l threshold between pre-season 15.5 km/h (95% CI: 15.6-15.5) to in season 15.6 km/h (95% CI: 15.7-15.6). Neither IAT nor velocity at 4mmol/l lactate differed significantly between the age groups U16, U17 and U19. Only the U23 collective showed significant differences in mean velocity on both respective thresholds by an average of 0.4 km/h compared to U16, U17 and U19 ( $p\leq 0.001$ ). However, no significant ( $p=0.56$ ) intra-individual improvements of both thresholds could be observed in the group of 50 PDP that were continuously monitored over at least 3 seasons. **Discussion** Surprisingly, our data show that between the age groups of U16, U17 and U19 no significant changes can be observed in a large cohort of PDP. The high but stable level of anaerobic capacity between the 3 younger age groups is corroborated by the finding that no intra-individual improvements of aerobic capacity could be observed. Given the data it is highly likely that the higher aerobic capacity in U23 players is based on a selection of players rather than an improvement of players over age. Longitudinal intervention or observation studies in cohorts of players younger than 15 years of age will have to clarify the aspect of how long and how effective aerobic endurance can be trained in elite soccer players. **References** Hoff J. ## RE-EXAMINATION OF THE POST HALF-TIME REDUCTION IN SOCCER WORK-RATE

LOVELL, R.1, BARRETT, S.1, PORTAS, M.2, WESTON, M.2

THE UNIVERSITY OF HULL

**RE-EXAMINATION OF THE POST HALF-TIME REDUCTION IN SOCCER WORK-RATE** Lovell, R.1, Barrett, S.1, Portas, M.2, Weston, M.2 1:University of Hull, UK. 2:Teesside University, UK. **Introduction** Studies have shown that the work-rate of soccer players is reduced in the first 15 minutes of the 2nd half of matches (46-60 min), in comparison to the corresponding phase in the 1st half (0-15 min; Bradley et al., 2009; Weston et al., 2011a). However, 15-min pre-determined segmentation of the game is not sensitive to the intricacies of the work-rate pattern (Drust et al., 2007) and a comparison yielded only small effect sizes (Weston et al., 2011a). Furthermore, using players' physical performances in the opening 5- or 15-min of the 1st half as a criterion to make subsequent inferences of fatigue, pacing or insufficient preparation is questionable given the intensity of the game at this stage (Weston et al., 2011b). Therefore, the aim of this study was to re-examine the work-rate of soccer players immediately after a passive half-time interval (HT). **Methods** Time motion analysis data (5 Hz GPS; MinimaxX, Catapult Innovations), were collected from 20 elite youth players (Age:  $17 \pm 1$  yrs;  $VO_{2max}$ :  $61 \pm 6$  ml•kg<sup>-1</sup>•min<sup>-1</sup>) during 21 competitive league fixtures (5  $\pm$  3 matches per player). Data were included from outfield players who participated in 90 min of match-play. Physical performances were categorised into total distance, total low-speed running (LSR: 0-14.9 km•h<sup>-1</sup>) and total high-speed running (HSR; 15.0-35.0 km•h<sup>-1</sup>). These dependent variables were subsequently time averaged into pre-determined periods of 5, and 45 minutes duration and expressed in relative (m•min<sup>-1</sup>) terms to allow direct comparisons between match periods of different lengths. During the 15-min HT players were passive (seated rest). **Results** There was a large reduction in relative total distance covered (ES 1.10), LSR (ES 0.95) and HSR (ES 1.04) during the opening 5-min phase of the second half (46-50 min) when compared to the 1st half mean (0-45 min). When comparing the 51-55 and 55-60-min periods, effect sizes were smaller for relative total distance covered (ES 0.01-0.11), LSR (ES 0.04-0.05) and HSR (ES 0.01-0.19). **Discussion** Players' work-rate was markedly lower in the first 5-min after a passive HT, although this phenomenon was transient in nature. Further research is required to determine if this phenomenon is caused by insufficient physical preparation as a consequence of a passive HT, or whether players adopt a sub-conscious pacing strategy to attenuate fatiguing symptoms in the latter stages of match-play. **References** Bradley PS, Sheldon W, Wooster B, Olsen P, Boanas P, Krstrup P. ## SPORTING CRIMINAL TO SPORTING CITIZEN: EMBODIED IDENTITY CHANGE AND THE REHABILITATIVE ROLE OF PHYSICAL ACTIVITY

DAY, J., SPARKES, A.C.

UNIVERSITY OF EXETER AND LIVERPOOL JOHN MOORES UNIVERSITY

**SPORTING CRIMINAL TO SPORTING CITIZEN: EMBODIED IDENTITY CHANGE AND THE REHABILITATIVE ROLE OF PHYSICAL ACTIVITY** Day, J. and Sparkes, A. C. **Introduction** Research into criminal activity has historically focused on how people have got into and stay involved in crime. Over the past thirty years interest has grown in how people get out and stay out of a criminal lifestyle and develop an adaptive pro-social identity and lifestyle. The Social Exclusion Report (2002) highlights nine key factors that influence re-offending one of which is mental and physical health. Within the Criminal Justice System there exist a range of sport and physical activity interventions designed to give people an opportunity to improve their health and well-being and facilitate their rehabilitation. A review of the literature and empirical studies indicates there is a need to develop the theoretical understanding of how these may or may not play a rehabilitative role. Some scholars

have commented that the impact of sport on crime is indirect and may work through other processes such as the development of personal and social goals (Bailey, 2005). Method A narrative research study was undertaken to examine the lived experience of people with criminal convictions that are trying to live a pro-social lifestyle. The research explored people's stories about the change process and the role played by sport and physical activity. Life history interviews were undertaken with sixteen people at different stages of change and semi-structured interviews with fourteen Criminal Justice staff. Results A narrative and thematic analysis was undertaken of the interview data. Case examples will be used to highlight seven key themes with a focus on the 'success' stories and the embodied nature of life transformation. The results aim to unpack and explore the complex relationship of identity change and the rehabilitative role of physical activity. Demonstrated are the benefits and the difficulties that may arise in making sense of how physical activity can contribute to people's attempts to 'go straight'. Discussion The implications for theorising about the rehabilitative role of sport and physical activity within the Criminal Justice System will be considered. In particular, the importance of available narratives resources to enable change, the holistic nature of identity and lifestyle change, and the benefits of considering an embodied perspective to offender rehabilitation. ### THE BODY AS A FOCAL POINT

HOGENOVA, A.

CHARLES UNIVERSITY

The body as a focal point Prof. PhDr. Anna Hogenová, Ph.D. Department of Philosophy Charles University Pedagogical Faculty Rettigové 4 Prague 1 11639 Our body should never be divided if we want to understand the essence of human existence, where sports also belong. The material and spiritual parts of our being should not be studied separately even if at first sight it seems quite logical and obvious. Obviousness is always an indication of that which something elemental conceals. Sporting achievement should be understood as a focal point of life's strength. This is also true for all other forms of human existence. Hence, it is necessary to describe sporting achievement as the result of the unity of physical and spiritual activity (but also passivity), which is in the form of a focal point, i.e. simplicity. The issue of the simplicity of human life is hidden within intentionality, which is the origin of the focal activity of man. This unity is best displayed through sport, but it is also the most neglected. An analytical – Cartesian approach is the most important methodological assumption even when examining the human body. This article focuses on an explanation of intentionality (mental inexistence). This phenomenon was discovered by Aristotle, later by Tomáš Akvinský and later still by Brentano. Edmund Husserl adapted Brentano's meaning of it and based his phenomenology on it. This article explains the essence of human exploit in the current functioning of the physical and spiritual parts of our being through protentionality in our flow of cogitations. From this point of view we want to familiarize the student with the body image as a basic condition of the focal understanding of human movement in sport. The body image is a background from which we derive the focal point of movement linked with physical and spiritual potential. It is a familiarization with the phenomenon of intentionality. The achievement of an athlete is always simplicity, a focal release of the athlete's whole being, where cognitivity, emotion and will, and memory cannot be separated from physical predisposition. ### INDIGENOUS PEOPLES GAMES: GENDER, IDENTITY AND CULTURAL DIVERSITY

ROCHA FERREIRA, M., CAMARGO, V.R.T.

UNICAMP

Indigenous games are part of the material and immaterial patrimonial richness of the continents. This paper aims to study the Brazilian Indigenous Peoples Games as a local to build up new indigenous identities for male and female and cultures diversities. In the last centuries, the contact with European invaders brought about significant changes within native societies, such as high indices of mortality as a result of epidemics, hunger, wars, displacements, confinements and slave labor. Furthermore, the pacification process and, later on, the introduction of indigenous peoples into the national states was always tumultuous, without acknowledgment of cultural diversity. The present state of cultural and linguistic revitalization is a consequence of a socio-historical process for each ethnical group in the country. Many of the traditional games were inserted into sacred ceremonies and rituals and 'forced' to be forgotten. In the last decades the processes of new indigenous movements in politics, economy, education, health and sport have affected the national picture. METHODS The data was obtained through the bibliographies and ethnographic research in the 10 editions of National Indigenous Peoples Games, 1996 – to – 2009. The organizers, the chiefs (caciques) or their local representatives, plus sports leaders and "indigenous athletes" were interviewed inside the lodgings of the games. RESULTS AND CONCLUSIONS The Indigenous Peoples Games express the growing significance worldwide of indigenous cultural politics. They are initiatives of the Intertribal Committee of Indigenous Memory and Science integrate with the Ministry of Sports, the National Indigenous Foundation (FUNAI), the State and Municipality Secretariat of Sports and other institutions. The events give opportunities for the indigenous and now indigenous peoples to exchange experiences, to fraternize, to learn how to know and respect other ethnic groups and languages, to show and to renew their culture, traditions and values, to affirm their rights, to sell their arts and crafts, to play football (male and female), to show their "differences" to white people and thus obtain acknowledgement. They represent important places for the women to build up new social roles, such as players and athletes, to affirm the women rights in front of the indigenous male and in the national society and to re-think their social role in their settlements and in the national society. ### DOPING IN SPAIN FROM THE PERSPECTIVE OF THE PROFESSIONAL TEAM MANAGERS OF THE FUTURE: COMPARISON BETWEEN FORMER AMATEUR VS PROFESSIONAL CYCLISTS

FREIRE, C., MORENTE-SÁNCHEZ, J., FEMIA-MARZO, P., SÁNCHEZ-MUÑOZ, C., ZABALA, M.

UNIVERSITY OF GRANADA

Introduction Events occurred in recent years such as "Operation Puerto" in 2006 or the dispossession of the Tour of France to Floyd Landis in the same year made cycling lose much of its credibility from a social point of view (1). However, perspective about cycling is different depending on who, when and where is questioned (2). The objective of this study was to know the opinion of the future Spanish profes-

sional team managers in relation to the phenomenon of doping in cycling, discriminating according to their former cyclist experience (amateur vs professional). Methods The study included a total of 87 participants involved in the course to be professional Team Manager in Cycling (highest level) during 2009 and 2010 years (all of them passed and got the license). Of the total sample, 40 students had been "Professional" cyclists and 29 were cyclists until "Amateur" category. A descriptive design was carried out using a specific questionnaire consisting in 7 free-response questions, and then answers were analyzed and categorized. Results The data obtained, in percentage, comparing the responses of professional vs amateur categories, were: 1-Words associated with doping: Cheating (75.86% vs 45%), Money (34.4% vs 45%). 2- Responsible agents of Doping: Laboratories (62.07% vs 67.15%), Coach / Manager (86.21% vs 52.50%). 3- Differences Cycling vs Other sports: Media Impact (62.07% vs 30%), Discriminatory treatment (79.31% vs 67.5%). 4-Reasons for initiation in doping: Sport achievements (58.62% vs 37.5%), Contract / money (65.52% vs 35%), External pressure (44.83% vs 47.5%). 5 - Have you been suggested to dope?: Amateur (Yes 62.1%) vs Professional (Yes 67.5%). 6 - Have you seen another person inciting/being incited?: Amateur (Yes 62.1%) vs Professional (Yes 70%). 7- Proposed solutions: Prevention at early age (58.62% vs 30%), More controls and punishment (44.83% vs 27.15%). Discussion The results of this study show the problem of doping is recognized both by amateur and professional cyclists. The amateur relates it to 'cheating' possibly motivated for getting a 'better contract', while professionals links it to 'money' being 'external pressures' towards achieving the 'sporting achievement' (1). Coaches/managers are the main responsible for the amateur, while professionals focus their attention on the laboratories. Both believe there is a discriminatory treatment by media in relation to other sports. It is claimed prevention in early ages and an increase in punishment. It would be interesting to propose similar studies in other categories and sports to make comparisons. References Waddington I, Smith A et al. (2009). *Drugs in sport. #### REFLECTION AND ATTAINED SENIOR COMPETITIVE LEVEL

JONKER, L.1, ELFERINK-GEMSER, M.T.1,2, VISSCHER, C.1,2

1: UMCG, RUG (GRONINGEN, THE NETHERLANDS), 2: HAN UNIVERSITY OF APPLIED SCIENCES (NIMEGEN, THE NETHERLANDS)

Introduction Elite youth athletes commit to extensive numbers of training hours (Ericsson et al., 1993), but what they derive from training may be even more important to reach senior elite level. The best athletes learn more efficiently and discriminate themselves on reflection (Jonker et al., 2010). Reflection is the capacity to use past knowledge to improve in the future (Cleary & Zimmerman, 2001; Ertmer & Newby, 1996). Our purpose was to longitudinally assess reflection in elite youth athletes 4 years before their transition up to the moment of transition. Methods Participants were 54 elite youth athletes. Of them, 19 attained senior international status and 35 became nationals. In the 4-year period before transition, they had between 6.5 (sd=3.6) and 10.3 (sd=2.7) years sport experience and trained between 6.5 (sd=3.2) and 17.7 (sd=10.5) hours per week. 141 measurements were obtained on a yearly basis starting 4 years before transition. Multilevel modelling was applied to observe developmental trends in reflection measured with the SRL-SRS (Toering et al., in press). The effects on reflection of senior and junior competitive level, sport training, sport experience, type of sport (team or individual) and gender were tested. A randomly assigned control group (n=14) was used to verify the model with a Wilcoxon test. For all tests,  $p < .05$  was adopted. Results In the 4-year period before transition, senior internationals had higher scores on reflection than nationals ( $t=2.870$ ,  $df=1$ ,  $p < .01$ ). The use of reflection was stable for both the senior internationals and nationals 4 years before the transition up to the moment of transition ( $t=.676$ ,  $df=1$ ,  $p > .05$ ). No other significant results were found ( $p > .05$ ). By knowing the score on reflection before transition, the senior competitive level can be predicted: senior competitive level = (reflection - 4.079) / 0.264. The control group showed that predicted scores did not differ significantly from actual scores ( $z=-1.505$ ,  $p > .05$ ) and confirmed model fit. Discussion This study shows that what elite youth athletes derive from training, for example by means of reflection, is related to the attained senior competitive level. Regardless of junior competitive level, type of sport and gender, and with similar numbers of sport training and experience, results suggest that elite youth athletes' reflection scores can assist in predicting which athletes have the best chance to reach the top. #### THE QUIET EYE PERIOD AND PERFORMANCE FAILURE UNDER PRESSURE

VINE, S.J., MOORE, L., WILSON, M.R.

UNIVERSITY OF EXETER

Introduction Research has shown that the Quiet Eye (QE; Vickers, 1996) is an optimal visuomotor strategy that underlies highly skilled performance in a range of visuomotor tasks. However, the QE is susceptible to shortening under pressure, leading to reductions in accuracy (Vine & Wilson, 2010; Vine, Moore & Wilson, 2011). The aim of this study was to examine changes in the QE at the specific point of performance failure in a pressurised putting task. Methods Seventeen elite golfers (mean age = 21.23, SD = 2.63; mean handicap = 2.72, SD = 1.95) performed putts on an artificial putting green from 5 feet and were instructed to successfully hole as many balls as possible until they missed. Anxiety was manipulated by offering financial incentives and non contingent feedback, and measured before and after putting using the mental readiness form 3 (MRF-3; Krane, 1994). Gaze was recorded using an ASL mobile eye tracker. QE onset, offset and duration were calculated for the penultimate and final (missed) putts and subjected to paired sample t-tests. Results Anxiety was significantly increased as a result of the manipulation (7.4 vs. 3.0;  $t(16) = 17.65$ ,  $p < .001$ ). There were no significant differences in QE onset between the penultimate and final putt; but significantly earlier QE offset (2574 vs. 3607;  $t(16) = 2.86$ ,  $p < .05$ ) and significantly shorter QE durations (1492 vs. 2216;  $t(16) = 3.60$ ,  $p < .005$ ). Conclusions Performance failure, due to pressure, may be caused by an early QE offset leading to reduced QE durations. Performers should attempt to maintain effective QE durations at the specific point of pressure to prevent performance breakdown. References Krane, V. (1994). ### **SELF-ORIENTED PERFECTIONISM IN SPORT: A SIGN OF EVENTUAL SUCCESS OR MOTIVATIONAL VULNERABILITY?**

HILL, A.

*YORK ST JOHN UNIVERSITY*

Few athletes are equipped to cope with the physical and psychological demands of elite sport. A number of sport psychologists have suggested that perfectionism may be a hallmark characteristic of elite athletes (e.g., Anshel & Eom, 2002; Dunn, Causgrove, Dunn, & Syrotuik, 2002; Henschen, 2000). However, while a total commitment to exceptionally high standards is considered essential for high achievement (Weinberg, Burton, Yukelson, & Wiegand, 2000), some have argued that poorer psychological adjustment and negative achievement behaviours are likely to be evident in athletes who are characterised by higher levels of perfectionism (Flett & Hewitt, 2005). One particular dimension of perfectionism that has been found to have a number of positive features is self-oriented perfectionism (Hewitt & Flett, 1991). This entails a personal commitment to exceptionally high standards and intolerance of substandard performance. In a similar manner to the broader debate, the nature of self-oriented perfectionism is unclear. Empirical examination of self-oriented perfectionism outside of sport has failed to resolve this debate. Some research suggests that this dimension may lead to psychological difficulties (e.g., Blankstein, Lumley, & Crawford, 2007; Flett, Hewitt, Blankstein, Mosher, 1995; Hewitt et al., 2002), while other studies suggest that it may be a component of positive achievement striving (e.g., Bieling, Israeli & Antony 2004; Enns, Cox, & Clara, 2002; Frost, Heimberg, Holt, Mattia & Neubauer, 1993). A series of studies examined the correlates of self-oriented perfectionism amongst athletes and the manner in which athletes with higher levels of self-oriented perfectionism respond to achievement difficulties. The findings of these studies suggest that self-oriented perfectionism energises a distinct pattern of engagement that includes both high levels of commitment but also motivational vulnerability. The findings provide support for those who suggest self-oriented perfectionism is likely to be problematic for athletes (e.g., Flett & Hewitt, 2005, 2006). Self-oriented perfectionism appears to be best considered a vulnerability factor that may render athletes vulnerable to psychological and motivational problems if personal goals are thwarted.

### **BRINGING SELF-DETERMINATION THEORY AND THE REALITIES OF COACHING SOCCER TO DISADVANTAGED YOUTH CLOSER TOGETHER**

COWAN, D., TAYLOR, I.M., BAKER, J.S.

*UNIVERSITY OF THE WEST OF SCOTLAND*

**Introduction** Self-determination theory (SDT; Ryan & Deci, 2002) provides a useful framework for investigating coach behaviours and the subsequent impact on adolescents participating in sport. Nonetheless, existing research has largely employed self-report measures to assess the general motivational environment and is based on the assumption that coach behaviours advocated by self-determination theorists are easily applicable to the sport context. We aimed to extend this research by qualitatively exploring coaching behaviours in a soccer programme aimed at promoting life skills to disadvantaged youth. Specifically, we investigated the complex, real-world relationships between SDT-based coaching behaviours and whether theoretically adaptive behaviours are easily transferred to the soccer context. **Methods** The primary author immersed himself in a 13-week soccer-based educational programme for young people who are not in education, employment or training. Following this, with the second author acting as a critical friend, SDT was used to interpret data from multiple sources, such as observations, field notes, video footage, and interviews with the participants. **Results and Discussion** In some circumstances, employing autonomy supportive strategies without appropriate levels of structure may have been counterproductive because participants lacked the belief and knowledge to seize opportunities to take leadership roles, responsibility and make appropriate choices. Further, coaches who were interpersonally involved with participants, in particular those who successfully built relationships through the use of humour, were able to offset some negative consequences of controlling and theoretically maladaptive coach behaviours. Finally, the presiding authoritarian coach culture in soccer provided an obstacle to the integration of some coach behaviours advocated by self-determination theorists. Overall, this study gives new insight into the complex relationships that exist between SDT-based coaching behaviours and the influence that the soccer context may have on these relationships. **References** Ryan, R. M., & Deci, E. L. (2002). An overview of self-determination theory: An organismic-dialectical perspective. In E. L. Deci & R. M. Ryan (Eds.), *Handbook of self-determination research* (pp. 3-33). ### **IS HEART RATE VARIABILITY THE KEY TO UNDERSTANDING THE LINK BETWEEN EMOTIONS AND DECISION-MAKING IN SPORTS?**

LABORDE, S.

*GERMAN SPORT UNIVERSITY*

**Introduction:** It has become apparent that, in order to fully understand the decision-making of athletes, it is necessary to explore the option-generation process. This requires moving away from final choice as the ultimate factor. However, the emotional state of the athlete while making a decision has seldom been taken into account. The aim of this study is to fill this gap. More specifically, we seek to understand the influence of emotions on the option-generation process of athletes. This approach takes into account both subjective and physiological components of emotions. **Methods:** Ninety handball players (30 non-experts, 30 near-experts, and 30 experts) were involved in the study. The participants came twice to the lab, once for a familiarization session, and a second time for the experimental task. A between-subject design was used, with three emotional conditions: positive, neutral, and negative. Their emotions were successfully manipulated using, for example, music and imagery. The experiment included an option-generation task, with 31 3D video clips of handball attack situations. The decision-making process of athletes was operationalized using six dependent variables, assessing decision quality and efficiency. The options generated were recorded using audio software. The subjective component of emotions was assessed by the PANAS. The physiological component (i.e., heart rate variability, or HRV) was measured with the Nexus 4 device. **Results:** A MANOVA indicated no session effect for the choice variables. Further correlation analyses were run, between the decision-making variables, the PANAS, and HRV. Very weak relationships were found with the PANAS, whereas strong relationships were found with HRV. More specifically, the LF/HF ratio was found to be significantly related with decision time ( $r = .25$ ), with generation time ( $r = .24$ ), with the quality of initial option ( $r = -.21$ ), and with the mean quality of options ( $r = -.24$ ). **Discussion:** Our findings show, that HRV influences the decision-making process of athletes, and more precisely the option-generation process. In effect, the lower the LF/HF ratio, the better and faster the decision. This corresponds to the neurophysiological integration model (Thayer, Hansen, Saus-Rose, & Johnsen, 2009), in which

a vagally mediated HRV was found to improve the functioning of cognitive processes. Further research should explore the influence of HRV biofeedback training on decision-making, and also verify the results for task-specificity. Thayer, J. F., Hansen, A., Saus-Rose, E., & Johnsen, B. (2009). ### UNIQUE ENVIRONMENTS AND THE PERSONAL QUALITIES OF SPORT PSYCHOLOGISTS: A SPORTS MEDIC PERSPECTIVE

CHANDLER, C., EUBANK, M., NESTI, M.

LIVERPOOL JOHN MOORES UNIVERSITY

Understanding of the skills and characteristics that make Sport Psychologists effective has been informed by coach/athlete perceptions and practitioners' own reflective accounts (Gould et al, 1991; Lindsay et al, 2007). The personal qualities that underpin Sport Psychologists' effectiveness remain relatively unexplored, yet it is these qualities, such as self-awareness and self-knowledge, that are important for effective practice (Ravizza, 2002). Moreover, Sport Psychologists will find themselves having to address organisational and cultural processes within their work and therefore need an awareness of the unique environments that exist. Such environments can be volatile and arduous, and it is argued that Sport Psychologists need to possess qualities such as resilience, commitment, presence, authenticity and empathy to survive (Nesti, 2004). The Health Professions Council (HPC) Standards of Proficiency (2009) require Sport Psychologists to consider the dynamics of their practice environment. This includes recognising the role of other professionals working within the multidisciplinary team and how to contribute effectively to it. Psychologists often work alongside Sports Medics whose practice, like that of the Sport Psychologist, has the potential for significant impact on athlete well-being. The importance of character and personal qualities as indicators of success within effective Medics has previously been documented, and resonates with this study given the often difficult and challenging environments within which they work (Glick, 2000). Sports Medics were therefore deemed to be a population who could offer genuine insights about the effective practice of Sport Psychologists within these environments. A sample of highly experienced Sports Medics, working in elite UK sport, was interviewed to gather their perspectives about Sport Psychologists' characters, and their effectiveness. Data uncovered several personal qualities considered necessary for effective Sport Psychology delivery, such as stability, empathy and honesty. These were discussed in relation to the Sport Psychologist's understanding of the environment, their role within that environment, and their ability to work as part of an interdisciplinary team. Comparisons to the literature on Sport Psychology provision and the potential impact of findings on practitioner education and training will be considered. Glick, S. M. ## Plenary sessions

### PS-PL01 NEW HORIZONS: For the Challenge of Reducing Sedentary Activity in Humans

#### PROMOTING A PHYSICALLY ACTIVE LIFESTYLE: SELF-REGULATION AND SELF-RESPONSIBILITY OR A NANNY KNOWS BEST?

VAN MECHELEN, W.

VU UNIVERSITY MEDICAL CENTER

Prevalence rates of physical inactivity are high worldwide, as are associated diseases. Physical inactivity has been identified as the fourth leading independent risk factor for global mortality (6% of deaths globally). In the WHO European Region physical inactivity: is estimated to account for nearly one million deaths per year, i.e. 10% of the total and accounts for 8.3 million disability-adjusted life-years (DALYs - about 5% of the total). Dealing with this important risk factor would reduce the risks of cardiovascular diseases, non-insulin dependent diabetes, hypertension, some forms of cancer, musculoskeletal diseases and psychological disorders. According to the most recent Eurobarometer data 60% of the European population states to never or rarely participate in organised sports and if it comes to engagement in regular physical activity only 27% say to do so (i.e. performing at least 5 times a week at least moderate intensity physical activity). Next to the recognition of physical inactivity as an independent risk factor for many chronic disease, regular physical activity and exercise are currently seen as 'medicine' in the treatment of many disease states. There are now f.i. position statements and recommendations regarding physical activity/exercise and: diabetes type II, hypertension, bone health, cancer, obesity, arthritis, pregnancy-related hypertension and mental health. Next to these health-related effects, physical inactivity has economic bearing also, f.i. because of its relationship with sick leave. Research has shown that physical activity at a vigorous intensity level for at least three times a week has a positive effect on sick leave. From a review conducted for the World Economic Forum and WHO on the 'effectiveness and economic impact of worksite interventions to promote physical activity and healthy diet' we have learned that such interventions yield a 1 in approx. 2-4,5 return on investment, both from the direct cost, as well as from the indirect cost perspective. So the question is not so much about more evidence on the relationship between physical (in-)activity and health, or on the therapeutic benefits of physical activity and exercise, but more on the implementation end of things; i.e. how do we get both the still healthy population as well as patients to become physically more active or to pick-up exercising? In answering this question the critical question should be asked whether or not physical inactivity is abnormal behaviour in an normal environment, or whether it is normal behaviour in an abnormal environment?, i.e. is it all about self-responsibility and self-regulation or are we in need of a Nanny State to help us out? Depending on the outcome of this question, action plans should be made. This is what this plenary talk will be about.

**PLEASE STAND! ISSUES AND CHALLENGES IN SEDENTARY BEHAVIOUR CHANGE**

BIDDLE, S.

*LOUGHBOROUGH UNIVERSITY*

Sedentary behaviour, or excessive sitting time, has become a significant research trend in the past few years. Many researchers previously interested only in physical activity are now investigating sedentary behaviour, either alone or alongside physical activity. Although not new, with Jerry Morris studying occupational sitting over 50 years ago, the current impetus is marked. In this presentation I will highlight: a). the little we seem to know about modifiable correlates of sedentary time; b). the weakness of studying only screen time; c). what we currently know from interventions designed to reduce sedentary time. I will also touch on issues of sedentary behaviour measurement and the implications this may have for intervention design. Illustrative examples from Project STAND – an RCT designed to reduce sitting time in young adults at risk of Type 2 diabetes – will be highlighted.

#### IS-PM04 The Biological Significance of Exercise and Heat Shock Proteins

##### EXERCISE-INDUCED INDUCTION OF HSPTS IN HUMAN SKELETAL MUSCLE

MORTON, J.

LIVERPOOL JOHN MOORES UNIVERSITY

Exercise-Induced Induction of HSPs in Human Skeletal Muscle James Morton, RISES, Liverpool John Moores University The study of the exercise-induced induction of the cytoprotective Heat Shock Protein (HSP) family is important for the exercise scientist as it may provide a valuable insight into the molecular mechanisms by which regular exercise provides increased protection against related and non-related stressors. As molecular chaperones, HSPs are also fundamental in facilitating the cellular remodelling processes inherent to the training response. Whilst the exercise-induced stress response of rodent skeletal muscle is relatively well characterised, data from humans are less conclusive. This presentation will review data from our laboratory and others which has attempted to characterise the stress response of human skeletal muscle as well as elucidate some of the cellular stressors and methodological factors influencing the magnitude of the response. Data indicate that acute endurance and resistance type exercise protocols increase the muscle content of ubiquitin,  $\alpha$ B-crystallin, HSP27, HSP60, HSC70 and HSP70. Although HSP transcription occurs during or within several hours post-exercise, time-course studies have typically demonstrated increases in protein content are only detectable within 1-2 days following exercise. However, comparison amongst studies is complicated by variations in exercise protocol (mode, intensity, duration, damaging, non-damaging), muscle group examined, predominant HSP measured and moreover, differences in subject characteristics both within and between studies (training status, recent activity levels, nutritional status, age, gender etc). Following non-damaging exercise (that induces no overt structural and functional damage), the stress response is thought to be mediated by redox signalling as opposed to increases in contracting muscle temperature per se. Following damaging exercise (that induces overt structural and functional damage), the stress response is likely initiated by mechanical damage to protein structure and further augmented by the secondary damage associated with inflammatory processes. Exercise training induces an increase in basal HSP levels which is dependent on a sustained and unknown dose of training as well as initial training status. Furthermore, trained subjects display an attenuated or abolished stress response to customary exercise, likely due to adaptations of basal HSP levels and the antioxidant system. Given the cytoprotective properties of HSPs, further work is needed to accurately characterise an exercise dose-response (e.g. intensity, duration, mode etc) relationship so as to devise an appropriate exercise intervention (specific to the population of interest) which may offer optimal HSP mediated cytoprotection. This is particularly important given the role of HSPs in modulating cell signalling pathways associated with health and disease such as diabetes and ageing.

##### HEAT SHOCK PROTEINS IN HEALTH AND DISEASE

HENSTRIDGE, D., BRUCE, C.R., FEBBRAIO, M.A.

BAKERIDI HEART & DIABETES INSTITUTE

We have recently identified an essential role of heat shock protein (Hsp) 72 in preventing insulin resistance in the context of high-fat feeding<sup>1</sup>. In this previous study, overexpression of Hsp72 was accompanied by a marked reduction in high fat diet-induced activation of JNK in skeletal muscle which is implicated in insulin resistance<sup>2</sup>. However, it is not possible to attribute this as the mechanism by which Hsp72 overexpression prevents the development of insulin resistance, since Hsp72 transgenic mice were protected from developing obesity despite having similar food intake when placed on a high fat diet<sup>1</sup>. In addition, markers of oxidative capacity in skeletal muscle were increased in Hsp72 transgenic mice<sup>1</sup>. These data are in agreement with our previous observations that correlate increased Hsp72 expression with mitochondrial enzyme activity in human skeletal muscle<sup>3</sup>. We now show that HSP72 expression plays a pivotal role in regulating skeletal muscle oxidative capacity. Skeletal muscle specific transgenic HSP72 (HSP72Tg) and control (WT) mice were fed a regular chow (chow) or high fat diet (HFD) for 10 weeks. While the HFD markedly increased ( $P<0.05$ ) body weight, intramuscular lipid accumulation (DAGs and TAGs) and induced insulin resistance in WT, no such effects were seen in HSP72Tg mice. Despite equivalent food intake, whole body oxygen consumption, fatty acid oxidation and oxidative enzyme activity in skeletal muscle were increased ( $P<0.05$ ) in HSP72Tg irrespective of diet. When subjected to an endurance exercise treadmill test, HSP72Tg mice displayed a 2-fold increase ( $P<0.05$ ) in running capacity relative to WT mice. Consistent with this oxidative phenotype, HSP72Tg mice exhibit a 50% increase in mitochondria and a significant increase in Tfam mRNA expression ( $P<0.05$ ). In contrast, HSP72 knockout (HSP72<sup>-/-</sup>) mice develop obesity and insulin resistance and display marked accumulation of lipid in skeletal muscle. In addition, oxygen uptake, insulin-stimulated glucose uptake and fatty acid oxidation rates are lower ( $P<0.05$ ), while fatty acid esterification rates higher ( $P<0.05$ ) in primary myocytes obtained from HSP72<sup>-/-</sup> mice compared with WT. Together, these data indicate that HSP72 prevents obesity and insulin resistance by increasing oxidative metabolism in skeletal muscle. 1. Chung, J., et al. HSP72 protects against obesity-induced insulin resistance. *Proc Natl Acad Sci U S A* 105, 1739-1744 (2008). 2. Hirosumi, J., et al. A central role for JNK in obesity and insulin resistance. *Nature* 420, 333-336 (2002). 3. **HSPS AND CELL SIGNALLING: EFFECT OF EXERCISE AND AGEING**

MC ARDLE, A., KAYANI, A.C., VASILAKI, A., CLOSE, G.L., LIGHTFOOT, A., SAKELLARIOU, G., MC ARDLE, F., JACKSON, M.J.

UNIVERSITY OF LIVERPOOL

ROS generation is increased in skeletal muscles of adult mice following a period of isometric contractions and this is associated with increased Heat shock protein (HSP) content of the muscle. In contrast ROS generation and the ability to activate a stress response are modified in skeletal muscle with age. Transgenic studies have demonstrated that this blunted stress response plays a key role in development of age-related functional deficits. Lifelong overexpression of the cytosolic HSP, HSP70 in skeletal muscle of mice prevented the age-related loss of specific force generation but not the age-related loss of maximum tetanic force generation observed in muscles of old wild type (WT) mice. Unlike muscles of old WT mice, HSP70 overexpression facilitated the complete recovery of force generation in EDL muscles of old transgenic mice at 28 days following a severe protocol of damaging lengthening contractions. This effect was mimicked in muscles of old WT mice treated with a pharmacological inducer of HSP70. The mechanisms by which lifelong or acute increased muscle content of HSP70 provide this protection are unclear although data demonstrate that lifelong overexpression of HSP70 results in a reduction in the accumulation of markers of oxidative stress in old mice and reverses the inability to activate NF $\kappa$ B following contractile activity. Lifelong overexpression of the mitochondrial chaperone, HSP10 in skeletal muscle of mice prevented the age-related loss of force and cross-sectional area observed in old WT mice and protected muscles of both adult and old mice from damage following contraction-induced injury. Studies have demonstrated that mice lacking Cu,Zn superoxide dismutase showed an accelerated loss of skeletal muscle mass and function and examination of adaptive responses in muscles of adult Sod1<sup>-/-</sup> mice show aberrant DNA binding activity of AP-1 and NF- $\kappa$ B similar to that observed in muscles of old WT mice also suggesting that aberrant HSP responses may play a role in the modified cytokine production seen in old age. These data demonstrate that the development of age-related muscle weakness and atrophy are not inevitable and strengthen the hypothesis of the involvement of mitochondrial dysfunction in the development of these deficits and the differential effects of different HSPs highlight the specific functions of individual HSPs in skeletal muscle. The mechanism responsible for the inability to activate a stress response in old muscle is unclear although modified signalling by Reactive Oxygen Species is thought to play a role. Data suggest that the defect occurs prior to dissociation of the Heat Shock transcription factor, HSF1 from an inactive to an active form in the cytosol since data from mice treated with the HSP90 inhibitor and HSF1 activator, 17-AAG, demonstrate an increased HSP70 content of skeletal muscles of adult and old mice. This work was funded by Research into Ageing, BBSRC, MRC and National Institutes of Health (USA).

**Invited symposia****IS-BN02 Control of Gait and Posture: Science and Rehabilitation****GOAL-DIRECTED BEHAVIOUR IN CHILDREN WITH CEREBRAL PALSY**

LEDEBT, A.

VU UNIVERSITY AMSTERDAM

Introduction Children with spastic hemiparetic cerebral palsy (SHCP) have reduced functional abilities in the limbs of the affected side. Most children with SHCP participate in daily activities although they might not perform as well as typically developed children. Reduced functional abilities are thought to be a combination of impairments such as spasticity, weakness, and also motor control deficits. Daily activities include frequent interceptive actions, which require tight coupling between posture, movement coordination and perception. Different studies are presented to shed some light on the coupling between movement and perception. Methods Two main paradigms were used: one investigates the bilateral coordination of the upper limbs while sitting and the other the walking, reaching and gaze behavior during the interception of a moving ball. Bimanual coordination was examined under conditions of visual feedback created by placing a glass screen, opaque screen or a mirror between the arms (Feltham et al., 2010). The 'mirror box' creates a visual illusion of a zero lag symmetric movement between two arms. Kinematics and muscular activity are reported. For the interception of a moving ball the children had to intercept a ball at three different velocities with their impaired or less-impaired hand (van Kampen et al., 2010). Results and discussion Bilateral coordination: children with SHCP had longer phases of eccentric activation and shorter phases of inactivation in the elbow flexor of the more impaired arm during the glass condition compared to the screen and mirror condition. Furthermore, they had shorter phases of concentric activation in the elbow extensor of the more impaired arm during the mirror condition compared to the screen and glass condition. The effects of the availability of visual feedback in children with SHCP are explained by the matching of the afferent visual feedback with the efference copy, which overrides the neuromuscular activation (Smorenburg et al., 2011). Interceptive action: when was grasped with the impaired hand, children initially moved faster to the interception point. It showed that children with SHCP were able to take their impairment into account. However, these adjustments in walking velocity were not sufficient to compensate totally for the limited reaching ability in the impaired hand. Analysis of eye movements showed that some of the children with SHCP relied more on constant visual control during the entire interceptive action. **VIRTUAL REHABILITATION IN CEREBRAL PALSY: FROM MAGIC CARPET TO GOBLIN POST OFFICE**

BARTON, G.J.1, HAWKEN, M.B.1, FOSTER, R.J.1, HOLMES, G.2, BUTLER, P.B.3

1:LIVERPOOL JOHN MOORES UNIVERSITY 2:ALDER HEY CHILDREN'S NHS FOUNDATION TRUST 3:THE MOVEMENT CENTRE

Virtual Rehabilitation Virtual reality is a computer generated simulation of the real world in which the user can interact with a virtual environment through a human-machine interface (Holden, 2005). There is a growing interest in applying virtual reality in a movement rehabilitation context. A computer based reactive environment provides the key elements of motor learning – repetition, feedback, and motivation (Rizzo et al., 2002). Improvement of reduced core control in cerebral palsy The primary abnormalities characterising cerebral palsy (CP) include loss of selective muscle control, muscle imbalance and deficient equilibrium reactions (Gage and Novacheck, 2001). These abnormalities affecting the pelvis and trunk lead to reduced stability and control of the core which reduces mobility of distal body segments leading to inefficient performance of activities of daily living. There is evidence that primary problems resulting from brain damage improve in response to specific exercises that take advantage of the brain's capacity to reorganise. Virtual reality based com-

puter games can focus on control of specific movements, and provide enhanced motivation for continuing these training exercises. Projects Custom made computer games were created for the CAREN system, which were used to test and train movement control of the core. A series of studies were conducted both with healthy controls and children with CP aiming to improve selective movement control of the core and consequential improvement of movement function. Quantification of game performance ranged from simple methods of movement variability or straightness of flight trajectories to determination of the maximal settled speed which develops as a result of an adaptive algorithm adjusting forward speed of the games. Findings derived from virtual rehabilitation games Initial studies focused on the learning process of controlling pelvic and trunk rotations to drive a real-time game (Foster et al., 2008). The effect of game speed on performance was examined (Hawkins et al., 2008). Segmental differences of control were established in children with CP before games training (Barton et al., 2009). In a pilot study the performance of children with CP was followed through a six-week period of games. Indications of altered selective control could also be derived from dynamic coupling between the trunk and pelvis. References Holden MK (2005). *Cyberpsychol Behav*, 8, 187-211. ### VISUAL GUIDANCE OF WALKING IN OBESE CHILDREN

LENOIR, M., D'HONDT, E., DE BOURDEAUDHUIJ, I., DEFORCHE, B.

UNIVERSITY OF GHENT

Introduction It is well documented that childhood obesity has a negative impact on the motor competence. The presence of excess mass and a not-optimal distribution of that mass over the body hampers a smooth execution of motor task, especially in tasks that imply a displacement of (parts of) the body, like running or jumping. An alternative, but not exclusive, explanation for the lower motor competence in obese children is a lower quality of perceptual-motor functioning (D'Hondt et al., 2008). This study investigates the integrity of perceptual-motor functioning by manipulating visual information during walking. Methods Sixteen obese children (OB; BMI 29.92 +/- 4.90) between 7 and 12 years and sixteen normal weight control children (NW; BMI 17.46 +/- 1.85) walked barefoot on an instrumented walkway at a constant self-selected speed. In the LIGHT condition, the room was normally lit, while in the DARK condition the room was completely darkened with the exception of a small light source at the end of the walkway. 3-D kinematics were collected through 8 infrared Proreflex cameras at 240 Hz. Data were averaged over the gait cycles of five trials in each experimental condition. Analyses of variance (2 (BMI group) x 2 (visual condition)) with repeated measures on the last factor were performed on each dependent variable. Significance level was set at  $p < .05$ . Results The walking pattern of obese children was characterized by a larger step width ( $p < .001$ ), but no significant difference in walking speed, or any other spatiotemporal parameter, although they tended to walk slower as compared to their normal-weight peers. The visual manipulation resulted in a more conservative gait pattern, featured by a lower speed, cadence, and step length, but a larger step width in the DARK condition (all  $p$ -values  $< .001$ ). Significant interaction effects on about half of the spatiotemporal parameters showed that the obese group was much more vulnerable to the absence of visual information, resulting in more time spent in stance phases in the DARK, while these differences were less pronounced in the normal-weight group. Conclusions In sum, the adaptations to the gait pattern in the absence of light are indicative of a safer walking pattern in both the obese and the normal-weight children. The greater impact of altered visual conditions on obese children's walking suggest that they might differently cope with sensory information during walking. This supports the hypothesis that differences in behavior between obese and normal-weight children might not solely be a problem of mechanics, but also a perceptual-motor problem. References D'Hondt, E., Deforche, B., De Bourdeaudhuij, & Lenoir, M. et al. (2010). Childhood obesity affects fine motor skill performance under different postural constraints. *Neuroscience Letters*, 440, 72-75.

#### IS-SH03 Gender and Physical Education

### EUROPEAN CHALLENGES: MIGRATION, GENDER, CULTURAL AND RELIGIOUS DIVERSITY - NARRATIVES OF MUSLIM GIRLS AND WOMEN

BENN, T.

UNIVERSITY OF BIRMINGHAM

One reality for Europe is the continued presence and growth of cultural and religious diversity as migrant populations increase, with Islam as Europe's second largest religion (Fekete 2008). This presentation focuses on the reality that physical education / sport structures, policies and practices can exclude young people who have cultural and religious needs that may differ from those in the mainstream education system (Dagkas et al 2011). Muslim girls and women (pupils and teachers) can experience greater disadvantage than boys and men in sport-related spaces. The focus, then, is on intersections of gender, ethnicity and religion. How can providers achieve more inclusive practice in and beyond schools? Although unified by belief in common tenets of Islam, the life experiences of Muslim people are diverse, influenced by many factors. These include family, religiosity and the adoption of private or public manifestations of faith, for example women's wearing of the hijab (head covering). Challenges in schools can arise when the religious needs of Muslim girls cannot be met, usually involving attention to requirements for body modesty and, for some, gender segregation for practical physical activities. Case studies (eg UK and Denmark) are used to explore the interface of Muslim girls'/ women's experiences in compulsory schooling and the dilemmas for providers. The cases illustrate girls' negotiation of positioning and the importance of context, historical, political and socio-cultural situation, in determining decision-making on inclusive policy and practice in physical education and sport in schools (Benn et al 2011, With-Nielson & Pfister 2011). **DANCE AND THE GENDER WARS – NARRATIVES OF BOYS AND MEN WHO DANCE**

GARD, M.

*CHARLES STURT UNIVERSITY*

We have moved into a period of history when scientific theories about the 'true' differences between males and females are resurgent (Fine 2010). This is perhaps not as inevitable as some might assume. Although new forms of biological determinism based on neo-evolutionary ideas appeared in the early 1970s, sparking bitter debates inside and outside academia, their sheer crudeness and lack of rigour could well have spelt the end of the enterprise (Lewontin 1993). However, particularly from the beginning of the early 1990s onwards, a combination of genetic and neurological science has reinvigorated the search for 'hard-wired' differences between the sexes (Jordan-Young 2010). Assuming that one is inclined to do so, there are many ways of challenging biological determinism. In this paper I read my qualitative research interviews with boys and men who dance against the claims that are made about 'natural' masculinity. These males appear, at least in the way they talk about themselves, to be a complex mixture of the stereotypically male and stereotypically female. For example, what are we to make of males who appear highly emotionally literate while also professionally competitive and avowedly heterosexual? Listening to the voices of different kinds of men is one way in which we can at least start to show not only how much more complex the world is than mars-vs-venus gender theories. These voices also hint that thinking in mars-vs-venus terms is not even a good place to start. In the 21st century, one of the most important struggles for freedom will centre on convincing people that biology is not destiny. Qualitative social science, especially researchers dealing with body disciplines such as sport and dance and in powerful places such as physical education, will have an important role to play. **EXTENDING PHYSICAL EDUCATION BEYOND THE CURRICULUM – NARRATIVES OF GIRLS WITH LEARNING DISABILITIES**

STRIDE, A., FITZGERALD, H.

*LEEDS METROPOLITAN UNIVERSITY*

There is an emerging tradition in sports research that seeks to value and recognize young people as key informants about their lives (O'Sullivan and MacPhail, 2010). Within this body of research there continues to be a lack of engagement with girls with learning disabilities. This absence reinforces wider discourses of inequality that position people with learning disabilities at the bottom of a disability hierarchy (Deal, 2003). We contend these deficiencies in research, and also sports practice, serve to reinforce a view that girls with learning disabilities matter less in sport than other performers. In this presentation, we want to rearticulate the position of learning disabled girls within notions of girlhood in ways that move beyond 'an invisible presence' (Erevelles and Mutua, 2005). We situate our presentation within an after-school football initiative that sought to forge a partnership between Bryant Park Special School and Liberty High School, both based in different suburbs within one city in the north of England. We ask the following question: How are after-school football initiatives, designed to enhance football opportunities and links between special and mainstream schools, being experienced by a range of stakeholders? In seeking to explore this question we offer a series of non-fiction narratives that capture the different ways in which a number of girls with learning disabilities, a male football coach and the male Head teacher of a special school experience the realities of the football initiative. These tales illustrate not only the practical challenges of attempting to enhance football opportunities but also the theoretical challenges of exploring intersectional discourses concerned with girls, learning disability and girlhood. **Invited symposia****IS-SH04 Talent Identification in Sport****HEY MATEY – ARE WE THERE YET? A FAIR DINKUM LOOK AT 25 YEARS OF NATIONAL TALENT IDENTIFICATION AND DEVELOPMENT IN AUSTRALIA**

GULBIN, J.

*AUSTRALIAN SPORTS COMMISSION*

Australia's first serious attempt at a sports specific talent identification and development (TID & D) program was pioneered by Australian Institute of Sport scientist Professor Allan Hahn commencing in 1987. Multiple rowing crews won gold medals at junior and senior world championships, and the Olympic Games. Emulating Dr Hahn's early success has proven exceedingly difficult despite the evolution of varying techniques and interventions that have now been trialled for 25 years. Despite the recognition that TID & D is one of the nine key pillars related to the success of a number of international sporting systems (De Bosscher et al, 2006), the reality of the Australian experience is that TID & D remains more "fringe" than mainstream. This is especially evident at a policy level. After two and half decades, it is only now that we are beginning to understand how TID & D best adds value to national sporting organisations, and what role TID & D could potentially play in achieving the broader outcomes of the high performance system. This presentation will condense 25 years into four key evolutionary periods - the concept, growth, refinement and maturation phases (Gulbin, 2011), and will use insights and examples to discuss if TID & D might actually reinvent itself as a key driver related to the optimisation of the talent development pathway. That is, based on the concept of deliberate programming (Bullock et al, 2009), TID & D becomes the key bridging discipline to ensure that an athlete has the highest probability of transitioning smoothly from a "grass-roots" participant to that of an elite performer. This is often easier said than done, and relies on a complex choreography of coach, athlete, sport, research and other system elements. ## IS IT WORTH EVALUATING PHYSICAL CAPACITIES IN TALENT IDENTIFICATION PROGRAMS?

BUCHHEIT, M.

*ASPIRE*

Contemporary research on talent identification lies on dynamic and multidimensional analyses of physiological, technical, tactical and psychological skills to establish the ultimate profile of talented and successful players (Vaeyens et al. 2008). While (young) elite players generally perform better on physical capacity-related tasks compared with sub-elite players (depending on the sport and the age considered), we seize the opportunity of this symposia to question and discuss the value of physical capacities as determinants of (physical) competitive performance in team sports, and in turn, the value of evaluating physical capacities in a talent identification (TID) perspective. 1. Since (young) elite players generally train more/better than their sub-elites, whether their greater physical capacities is the cause or the consequence of their high playing standard is difficult to evaluate. 2. While it is intuitive that greater physical capacities may help to win duels and increase scoring opportunities, there is no causal link between match physical performance and the final outcomes of a game (i.e., winning or losing). 3. Physical performance during games is not consistently reported to be greater in elite/more successful compared with sub-elite/ less successful teams (Rampinini et al. 2009), and the less successful teams can even run more (Dupont et al. 2011). 4. Match-induced physical fatigue does not always translate into reduced skill-related performance (Carling et al. 2011). 5. Recent data in youth soccer clearly show that playing positions likely constrain the expression of physical capacities during games (Buchheit et al. 2010, Mendez-Villanueva et al. 2011). 6. The increase in physical capacities with age in young soccer players is not associated with parallel increases in match running performance (Buchheit et al. 2010). 7. We all have anecdotal evidences of successful elite players that do not possess extraordinary physical capacities (i.e., "compensation phenomenon") (Vaeyens et al. 2008). While it is evident that 'who can do more, can also do less', there is a general feeling of overemphasis on the importance of physical capacities for successful team-sport match performance and long-term career at the elite level. More dynamic and longitudinal assessments of match activity profiles according to playing position, maturation status and physical capacities, as well as a better understanding of the match-associated physiological load and technical demands are still warranted to improve TID test batteries and long-term training interventions. ## HOW CAN I REACH THE TOP IN SPORTS?

ELFERINK-GEMSER, M.

*UNIVERSITY OF GRONINGEN, UMCG / HAN UNIVERSITY OF APPLIED SCIENCES*

Marije T. Elferink-Gemser<sup>1,2</sup>, Chris Visscher<sup>1,2</sup>: 1: Center for Human Movement Sciences, UMCG, University of Groningen, The Netherlands, 2: Institute for Studies in Sports and Exercise, HAN University of Applied Sciences, Nijmegen, The Netherlands Introduction Considerable resources are invested in identifying talented athletes at an early age (Vaeyens et al., 2008). Still, current talent identification programs focus mainly on the current level of performance in the sport youth athletes are already active in (Phillips et al., 2010). Method In the Groningen talent studies we aim to objectify what it is that characterized adult elite athletes in their youth. For this purpose, over a thousand talented athletes have been and are being followed for the last ten years into adulthood applying a longitudinal design, accounting for the relation between the sport performance, an athlete's personal multidimensional performance characteristics, and the environment (Elferink-Gemser et al., 2007). Results Successful athletes distinguish themselves from their less successful counterparts by a combination of sports-specific and general performance characteristics. On several characteristics such as technical skills, successful athletes outscore less successful athletes already by the age of 12 and remain better (Huijgen et al., 2009). On other characteristics, such as interval endurance capacity, differences in favour of the successful athletes develop over time with the age-band of 14-16 proving crucial (Roescher, 2010). Remarkable is the essential role of tactical skills (Kannekens et al., 2010) and the successful athletes' ability to profit maximally from training displayed by high levels of reflection and effort; aspects of self-regulation of learning (Jonker et al., 2010). Discussion Talent identification programs are encouraged to not merely focus on the current level of performance but in stead on the potential a youth athlete has to develop performance characteristics. The ultimate successful ones take responsibility for their own learning and development process which may help them accomplish their goals in reaching the top. This is reflected in the rate they improve themselves over time. Sport science can help by repeatedly constructing a profile of talented athletes' multidimensional characteristics. ### OP-PM01 Vascular Adaptation

#### ROLE OF REACTIVE OXYGEN SPECIES ON THE NITRIC OXIDE SYSTEM IN AGING HUMANS: IMPACT OF LIFELONG PHYSICAL ACTIVITY

NYBERG, M.1, BADA, A.A.2, HELLSTEN, Y.1, MORTENSEN, S.P.2

*1:UNIVERSITY OF COPENHAGEN, 2: RIGSHOSPITALET*

Introduction Nitric oxide (NO) is a potent vasodilator that contributes to the regulation of blood pressure and skeletal muscle blood flow at rest and potentially during exercise. An age-related increase in reactive oxygen species (ROS) may, however, critically affect the bioavailability of NO. Accordingly, the present study aimed to investigate whether the increase in blood pressure and attenuated skeletal muscle blood flow during exercise, often observed in aging humans, is associated with lowered NO availability due to enhanced ROS formation, and to what extent lifelong physical activity affects these systems. Methods We measured hemodynamics at rest and during one-leg

knee-extensor exercise (12 W and 45% Wmax) in healthy lifelong sedentary (SED; age:  $63 \pm 4$  years;  $\text{VO}_{2\text{max}}$ :  $23.8 \pm 0.9$  ml  $\text{O}_2$   $\text{min}^{-1}$   $\text{kg}^{-1}$ ; MAP:  $114 \pm 4$  mmHg) and healthy lifelong physically active (PA; age:  $64 \pm 3$  years;  $\text{VO}_{2\text{max}}$ :  $43.8 \pm 3.7$  ml  $\text{O}_2$   $\text{min}^{-1}$   $\text{kg}^{-1}$ ; MAP:  $98 \pm 2$  mmHg) male subjects without (CON) or with constant venous infusion of the antioxidant N-acetylcysteine (NAC) to scavenge ROS. Results Infusion of NAC increased resting leg blood flow (LBF) in both SED (~30%) and PA (~33%). There was no difference in LBF between SED and PA during the same absolute workload (12 W;  $1.7 \pm 0.1$  vs.  $1.6 \pm 0.1$  l  $\text{min}^{-1}$ ). NAC infusion did not affect LBF during exercise at 12 W (SED:  $1.6 \pm 0.1$  l  $\text{min}^{-1}$ ; PA:  $1.7 \pm 0.1$  l  $\text{min}^{-1}$ ) and 45% Wmax (SED ( $20 \pm 2$ W):  $2.3 \pm 0.2$  vs.  $2.2 \pm 0.2$  l  $\text{min}^{-1}$ ; PA ( $34 \pm 3$ W):  $2.8 \pm 0.4$  vs.  $2.7 \pm 0.4$  l  $\text{min}^{-1}$ ). Infusion of NAC lowered MAP during resting conditions in SED (~7%), during exercise at 12 W in both SED (~7%) and PA (~9%), and during 45 % Wmax in PA (~9%). Discussion The finding that antioxidant infusion lowered blood pressure at rest and during exercise and increased resting blood flow suggests that NO bioavailability is compromised due to increased formation of ROS in aging humans. Despite these effects, blood flow to the exercising leg remained unchanged with antioxidant infusion in both groups. This suggests that an age-related perturbation in the NO system, due to enhanced ROS formation, does not account for the lower blood flow during exercise in aging humans. Furthermore, lifelong physical activity does not affect the age-related attenuation in blood flow during exercise. Sources of funding: Lundbeck Foundation and Danish Medical Research Council.

### ASSESSMENT OF THE ACUTE EFFECTS OF CONTINUOUS AND HIGH-INTENSITY INTERVAL EXERCISE ON ENDOTHELIAL FUNCTION IN INDIVIDUALS WITH CORONARY ARTERY DISEASE

CURRIE, K.D.<sup>1</sup>, MCKELVIE, R.S.<sup>2</sup>, MACDONALD, M.J.<sup>1</sup>

*MCMMASTER UNIVERSITY*

**Introduction** Cardiovascular disease is characterized by decreased endothelial function (Zhang et al., 2000). Cardiac rehabilitation exercise training improves endothelial function (Vona et al., 2009) and typically involves continuous aerobic exercise (CON). The overload principle states that the exercise stimulus which causes the greatest acute stress on the body will result in the greatest chronic adaptations following training. This study investigated if CON and a novel high-intensity interval protocol (HIT) resulted in similar acute changes in endothelial function as predicted by the overload principle. **Methods** Ten individuals ( $66 \pm 11$  yrs) with coronary artery disease participated in 2 sessions. Endothelial function was measured pre and 60-minutes post-exercise. Endothelial-dependent function was assessed using flow-mediated dilation (FMD). Brachial artery diameters and velocities were collected using Doppler ultrasound at baseline, and for 90-seconds following a 5-minute ischemic period. Endothelial-independent function was assessed using a 0.4-mg sublingual dose of nitroglycerin (NTG). Diameters were collected at baseline and 3 and 4-minutes post administration. Exercise was performed on a cycle ergometer. CON involved 30-minutes at 55% of peak power output (PPO). HIT involved 10, 1-minute bouts at 80% PPO separated by 1-minute bouts at 10% PPO. **Results** Absolute FMD was increased ( $p=0.012$ ) following CON (pre:  $0.24 \pm 0.18$  mm, post:  $0.31 \pm 0.24$  mm) and HIT (pre:  $0.25 \pm 0.13$  mm, post:  $0.29 \pm 0.13$  mm), with no group differences. A time effect for FMD normalized to the shear stress area under the curve was also observed ( $p=0.021$ ) after CON (pre:  $0.005 \pm 0.004$ , post:  $0.010 \pm 0.011$ ) and HIT (pre:  $0.005 \pm 0.004$ , post:  $0.009 \pm 0.011$ ). Relative FMD (%), and absolute and relative NTG responses were unchanged following CON and HIT ( $p>0.05$ ). **Discussion** Contrary to our hypothesis, acute increases not impairments, in FMD responses were observed following CON and HIT. The increases in FMD, and unchanged NTG responses are in agreement with some previous acute exercise investigations (Harvey et al., 2005; Silvestro et al., 2002) and may highlight the acute physiological benefits of exercise in a clinical population. HIT is currently being used in a cardiac rehabilitation training study to assess chronic changes in endothelial function. **References** Zhang X et al. (2000). *Atherosclerosis*, 149, 19-24. **1** Research Institute for Sport and Exercise Science, Liverpool John Moores University, UK, **2** Department of Physiology, Radboud University Nijmegen Medical Centre, The Netherlands **3** School of Sport Science, Exercise and Health, The University of Western Australia **Introduction:** Exercise training is a potent stimulus to improvement in vascular function and is consequently associated with decreased cardiovascular risk. Animal studies indicate that episodic increases in shear stress are an important stimulus for vascular adaptation. Cycling exercise in humans is not only associated with changes in arterial shear stress, but also to large changes in blood pressure which is another potential haemodynamic stimulus for vascular adaptations. We examined bilateral brachial artery endothelial function across an 8 week period of cycling exercise training in healthy young men. Whilst both brachial arteries were exposed to the same blood pressure signal, we unilaterally manipulated shear stress by cuff inflation around the forearm. We hypothesised that attenuating shear stress would mitigate exercise-induced improvement in vascular adaptations. **Methods:** Nine healthy young males ( $22 \pm 1$  year) were recruited. Subjects performed three 30-min cycling exercise bouts/wk at 80% of their individual predicted maximum heart rate. During each bout, a cuff was inflated around one forearm to 60mmHg. Duplex ultrasound was used to measure bilateral brachial artery nitric oxide-mediated endothelial function (using flow-mediated dilatation; FMD) and dilation to glyceryl trinitrate (GTN: endothelium-independent dilation) at 0, 2, 4, 6 and 8 weeks. **Results:** A time-dependent change in brachial artery FMD was observed (ANOVA:  $P<0.05$ ). Brachial artery FMD in the non-cuffed arm significantly increased from  $5.8 \pm 4.1\%$  to  $8.6 \pm 3.8\%$  at week 2 (post hoc;  $P<0.01$ ) and returned towards baseline levels at week 4, 6 and 8 ( $7.4 \pm 3.5$ ,  $6.9 \pm 2.4$ , and  $6.0 \pm 2.3$ , respectively). No changes in FMD were observed in the cuffed arm. No changes in GTN-response across the 8-week period were found in the non-cuffed or cuffed forearm. **Discussion:** We observed a time-dependent change in brachial artery endothelial function in response to cycling training in healthy young men. When shear stress during exercise was attenuated by cuff inflation, no adaptations were observed. These data indicate that shear stress in humans is a key stimulus for adaptations in vascular function in humans.

**EXERCISE-MEDIATED CHANGES IN CONDUIT ARTERY WALL THICKNESS IN HUMANS: ROLE OF SHEAR STRESS**

VAN DEN MUNCKHOF, I.C.L., THIJSEN, D.H.J., TINKEN, T.M., DEN DRUIVER, E., HOPKINS, N., DAWSON, E.A., CABLE, N.T., GREEN, D.J.

*RADBOUD UNIVERSITY NIJMEGEN MEDICAL CENTRE*

**Background.** Exercise training is a potent stimulus to improve vascular function and artery wall thickness, changes associated with decreased progression of atherosclerosis. Whilst previous studies have demonstrated that shear stress is the principle stimulus for adaptations in vascular function, less is known about whether episodic increases in shear stress induce training-induced adaptation in arterial wall remodeling in humans. **Purpose.** To examine the role of shear stress in adaptations in wall thickness during 8-week handgrip training in healthy humans. We hypothesised that manipulation of exercise-induced shear stress would induce differences between the limbs in artery wall thickness. **Methods.** We examined bilateral brachial artery wall thickness using high-resolution ultrasound in healthy men across an 8-week period of bilateral handgrip training (2-weekly intervals). Exercise training was performed 4 times a week, using 30-min exercise bouts. During these exercise bouts, shear rate was attenuated unilaterally during every exercise bout by cuff inflation to 60 mmHg. **Results.** Grip strength, forearm volume and girth improved similarly between the limbs. Acute bouts of handgrip exercise increased shear rate ( $P < 0.005$ ) in the uncuffed limb, whereas cuff inflation successfully decreased exercise-induced increases in shear. Handgrip training had no effect on baseline brachial artery diameter, blood flow or shear rate. Exercise training significantly decreased brachial artery wall thickness from  $254 \pm 30 \mu\text{m}$  to  $231 \pm 23$  and  $228 \pm 22 \mu\text{m}$  after 6 and 8 weeks, respectively ( $P < 0.001$ ). Wall-to-lumen ratio decreased significantly from  $0.062 \pm 0.009$  to  $0.055 \pm 0.008$  after 8 week handgrip training ( $P = 0.005$ ). The decrease in brachial artery wall thickness and wall-to-lumen ratio after exercise training was similar in the uncuffed and cuffed arms ( $P = 0.49$  and  $0.51$ , respectively). **Conclusion.** These results demonstrate that exercise training in healthy young men leads to a time-dependent change in brachial artery wall thickness. Moreover, we provide evidence that exercise-induced increases in shear are not obligatory for conduit artery wall remodeling in response to exercise training in healthy subjects. In contrast to changes in artery lumen diameter and size, changes in wall thickness following exercise training are apparently related to systemic, rather than localised, hemodynamic stimuli.

**MICROVASCULAR ADAPTATIONS IN RESPONSE TO HIGH INTENSITY INTERVAL TRAINING IN SKELETAL MUSCLE**

COCKS, M.I., SHEPHERD, S.I., TIPTON, K.D.I., RANASINGHE, A.I., BARKER, T.I., SHAW, C.S.I., WAGENMAKERS, A.J.M.I

*UNIVERSITY OF BIRMINGHAM*

Structural and functional changes in skeletal muscle (SM) microvessels play an important role in the pathogenesis of insulin resistance and hypertension. Nitric oxide (NO) bioavailability influences both microvascular density and function. NO bioavailability is determined by its synthesis via endothelial nitric oxide synthase (eNOS), and scavenging through NAD(P)H-oxidase (NOX2) mediated generation of superoxide. High intensity interval training (HIT) elicits similar metabolic and macrovascular adaptations to traditional endurance training (ET). However, today its effects on the SM microvasculature have not been investigated. We therefore aimed to see if HIT elicited similar changes in capillary density and microvascular endothelial enzyme content (eNOS content and phosphorylation and NOX2-content) to ET. 16 Young sedentary males matched for age and BMI (mean age  $21 \pm 0.7$  y, BMI  $23.8 \pm 0.7 \text{ kg.m}^{-2}$ ) were randomly allocated to either HIT (performing 4-6 Wingate tests 3 times per week) or ET (performing 40-60 minutes of cycling at  $\sim 65\% \text{ VO}_{2\text{peak}}$ , for a period of 6 weeks). Muscle biopsies were taken from the vastus lateralis pre and post training. eNOS content and phosphorylation (eNOS Ser1177) and NOX2 content were assessed in the SM microvascular endothelium and sarcolemma (NOX2 only) using quantitative immunofluorescence microscopy. Capillary density was also determined using immunofluorescence microscopy. Both HIT and ET increased all measures of SM capillarization (capillary contacts per fibre, ET 20%, HIT 21%; individual capillary to fibre ratio, ET 22%, HIT 24%; capillary density, ET 32%, HIT 27%; main effects  $P < 0.05$ ). HIT caused an increase in SM microvascular eNOS content (36%;  $P < 0.05$ ) and although ET tended to increase eNOS this failed to reach significance (14%;  $P = 0.069$ ). Basal eNOS Ser1177 decreased following training (ET -13%, HIT -19%; main effects  $P < 0.05$ ) and endothelial and sarcolemmal NOX2 were unaltered by training (endothelial NOX2;  $P = 0.805$ , sarcolemma NOX2;  $P = 0.124$ ). While both ET and HIT are effective at increasing SM microvascular density, HIT appears more effective at increasing microvascular eNOS content. eNOS phosphorylation was reduced by training which may be related to a reduced shear stress stimulus resulting from the increased capillarization. NOX2 was unaltered by training, suggesting that any improvements in microvascular function in a young healthy but sedentary group are mediated by an increased production of NO rather than a reduction of NO scavenging. In conclusion, HIT is an effective and time efficient intervention to increase capillary density and microvascular eNOS expression with potential relevance to the treatment of insulin resistance and hypertension.

**Oral presentations****OP-BN03 Tendons/Stiffness****THE INFLUENCE OF LOADING ON MUSCLE-TENDON UNIT BEHAVIOUR DURING A STRETCH SHORTENING CYCLE KNEE EXTENSION TASK**

EARP, J.E., NEWTON, R.U., BLAZEVOICH, A.J.

*EDITH COWAN UNIVERSITY*

**Introduction** Differences in vastus lateralis (VL) muscle-tendon unit (MTU) behaviour have been examined as movement velocity is varied in isokinetic and jump-type stretch-shortening cycle (SSC) tasks. However, little is known about how muscle and tendon behaviour changes under different loading conditions during maximum velocity isoinertial movements. Such information is important as load variation is a critical variable in resistance training programmes. **Methodology** Eight healthy physically active men performed single-leg, maximum intensity isoinertial leg extensions at loads of 20, 60 and 90% of their one-repetition maximum. After warm-up and familiarisation, subjects performed three repetitions of each load with a full countermovement, during which VL fascicle behaviour was measured using ultrasonography (12.5 MHz freq., 95 Hz sampling rate). MTU length was estimated by entering goniometer-derived knee joint angles into a previously published model. Minimum and maximum fascicle length and lengthening-shortening velocity were obtained. Tendon-aponeurosis (TA) lengthening-shortening was estimated by subtracting the displacement of the aponeurosis-fascicle insertion from MTU lengthening-shortening distance. Variables were compared across loads using ascending paired t-tests ( $p < 0.05$ ). **Results** Fascicle shortening velocity significantly decreased as load increased (20%:  $69.2 \pm 47.7$ ; 60%:  $33.6 \pm 21.4$ ,  $p = 0.03$ ; 90%:  $23.3 \pm 13.6 \text{ cm.s}^{-1}$   $p = 0.03$ )

while no significant differences were found between loads for fascicle or TA lengthening velocity, which were consistent with the observed concentric and eccentric movement velocities. TA shortening velocity was significantly ( $p=0.01$ ) slower at 90% ( $11.93 \pm 5.58$  cm·s<sup>-1</sup>) than 60% ( $16.05 \pm 8.36$  cm·s<sup>-1</sup>) but no significant differences were found between 60% and 20% ( $17.02 \pm 7.66$  cm·s<sup>-1</sup>). Lastly, TA recoil tended to decrease as load increased (20%:  $11.2 \pm 2.1\%$ ; 60%:  $10.3 \pm 2.9\%$ ; 90%:  $9.1 \pm 1.4\%$ ), however this difference was only significant ( $p=0.03$ ) between 20 and 90%. Discussion The current findings that fascicle shortening velocity and TA recoil decrease and fascicle strain remains constant as counter movement load increases differ from previous findings in jumping, which show that fascicle strain decreased and TA strain increased with greater volitional intensity. This may be due to either the large range of motion of the leg extensions or the torque needed to overcome the downward momentum of the load, which could make it impractical for the muscle to work in a quasi-isometric state. The current study is the first to find differences in MTU behaviour between commonly used training loads, and may provide information as to the mechanical stimuli which will elicit load specific training adaptations in muscle and tendon.

## EFFECT OF AGEING ON QUADRICEPS MUSCULO-ARTICULAR AND MUSCLE STIFFNESS

DITROILO, M.1, CULLY, L.1, BOREHAM, C.A.G.2, DE VITO, G.1,2

1: SCHOOL OF PUBLIC HEALTH, PHYSIOTHERAPY AND POPULATION SCIENCE, UNIVERSITY COLLEGE DUBLIN, IRELAND; 2: INSTITUTE FOR SPORT AND HEALTH, UNIVERSITY COLLEGE DUBLIN, IRELAND

Introduction Musculo-articular stiffness (MAS) is a comprehensive measurement which includes stiffness of the muscle-tendon unit, along with that of the surrounding articular surfaces, ligaments, and skin and is often assessed with the free oscillation technique (Ditroilo et al, 2010). In contrast, a more localized and selective measurement of just muscle stiffness (MS) can be performed with a myometer (Bizzini and Mannion, 2003). It is well established that ageing is characterized by a loss in muscle mass and strength (Reeves et al, 2006). It is also known that ageing reduces tendon stiffness (Reeves et al, 2006), however its effect on stiffness of other biological components is yet to be well established. The aim of the present cross-sectional study was to assess MAS and MS in two groups of male subjects young and older in order to gain a better insight into how ageing affects stiffness of different biological structures. Methods Fourteen young (YM, age  $22.1 \pm 3.0$ y, height  $179.7 \pm 5.0$ cm, mass  $79.0 \pm 11.9$ kg) and 12 older sedentary men (OM, age  $65.4 \pm 5.7$ y, height  $171.2 \pm 6.9$ cm, mass  $82.7 \pm 11.6$ kg) were assessed for maximal isometric voluntary contraction (MVC), MAS and MS of the quadriceps (at 15% of MVC). Results were compared by using an independent t-test. Results The mean results were  $288.6 \pm 36.2$  and  $194.3 \pm 35.4$  Nm ( $p < 0.05$ ) for MVC;  $1239.8 \pm 235.0$  and  $951.8 \pm 220.0$  Nm<sup>-1</sup> ( $p < 0.05$ ) for MAS;  $435.4 \pm 70.3$  and  $387.7 \pm 71.1$  ( $p = 0.11$ ) for MS, in YM and OM, respectively. MAS normalized to individual load was not significantly different between groups ( $100.1 \pm 13.0$  vs  $101.3 \pm 16.0$  Nm<sup>-1</sup>kg<sup>-1</sup>,  $p = 0.81$ ), whereas OM displayed significantly higher values in MS ( $23.2 \pm 5.2$  vs  $18.6 \pm 4.6$  Nm<sup>-1</sup>kg<sup>-1</sup>,  $p < 0.05$ ). Discussion When the normalization procedure was implemented, so that the effect of the different loads supported was neutralized, it was interesting to notice that the differences in MAS between YM and OM disappeared. In contrast, MS appeared to be higher in OM. It has been previously reported that tendon stiffness, as measured by ultrasonography, is reduced by the ageing process (e.g. Reeves et al, 2006). When combining the latter results with the outcomes of this study it could be speculated that the overall level of MAS remained unaltered because an increase in MS was offset by a decrease in tendon stiffness. Although caution should be exercised when comparing results from various studies collected with different techniques, this seems to be a very interesting and promising scenario, warranting further research. ## ARE TENDON, JOINT AND LEG STIFFNESS MAJOR DETERMINANTS OF RUNNING ECONOMY IN WELL-TRAINED RUNNERS?

BLAZEVICH, A., COLEMAN, D.R., CANNAVAN, D., HORNE, S.

EDITH COWAN UNIVERSITY

Are tendon, joint and leg stiffness major determinants of running economy in well-trained runners? Anthony J. Blazevich[1,2], David R Coleman[1], Dale Cannavan[3] and Sara Horne[1] 1 Brunel University, London, UK. 2 Edith Cowan University, Perth, Australia. 3 Seattle Pacific University, Seattle, USA. The stiffness of an elastic system is a major determinant of both its natural oscillation frequency, the oscillation frequency at optimum oscillatory efficiency, and the peak force produced during recoil after stretching. Therefore, the stiffness of the lower limb during running (leg stiffness) and of the elastic structures that strongly influence leg stiffness (i.e. the Achilles and patellar tendons) have been hypothesised to influence the performance, and economy, of moderate-to-fast human running. However, few studies have examined the relation between running economy and the mechanical properties of the leg and its major tendons, and, particularly, no research has examined these relationships simultaneously in a single subject cohort in order to investigate possible interaction effects. Hence, the relative impact of each is unknown, and it is not clear whether stiffness of a particular tendon or joint is more predictive of running economy than another. In the present research, the relationship between running economy and tendon (Achilles and patellar), joint (ankle and knee) and whole leg stiffness (measured during running) was examined in 12 well-trained male middle distance runners. Leg stiffness was calculated from synchronously-obtained real-time motion analysis and forceplate data. Also, medial gastrocnemius (MG) and vastus lateralis (VL) tendon force-elongation properties were measured using in vivo ultrasonographic tendon visualisation during isometric maximal voluntary contractions, stiffness of the ankle and knee joints were calculated using inverse dynamics during running, and running economy was assessed by standard VO<sub>2</sub> measurements during an incremental treadmill protocol (0.5% grade). Using regression analyses, values for all variables were calculated at a running speed of 16 km/h. The data showed that MG tendon stiffness and peak isometric ankle joint moment were significantly correlated with economy ( $r = -0.66$  and  $-0.68$ , respectively), and each other, but leg and joint stiffness were not. Thus, a stiffer Achilles tendon and greater plantarflexor strength may provide a functional benefit by increasing the efficiency of the energetically demanding propulsive phase. However, analysis revealed no relationship between tendon, joint and leg stiffness, so both joint and leg stiffness during running must be determined largely by factors other than the stiffness of the major tendons. Determinants possibly include muscle activation patterns and/or the joint configuration of the leg during ground contact. Leg and joint stiffness values are therefore not reflective of tendon stiffness and cannot be used as a surrogate for it.

## ARCHITECTURE AND MECHANICS OF THE TENDINOUS INSCRIPTION – FASCICLE INTERACTION OF THE HUMAN SEMITENDINOSUS MUSCLE

KELLIS, E., GALANIS, N.

ARISTOTLE UNIVERSITY OF THESSALONIKI

**Introduction** The semitendinosus (ST) is one of the four components of the hamstring muscle group. A unique characteristic of the ST muscle is the presence of a tendinous inscription (TI) along its middle belly. To our knowledge, the mechanics of architecture relative to the TI have not investigated in human muscle. The aim of this study was to examine the TI using dissection (cadavers) and ultrasound (in vivo). **Method** Ultrasonography (US) scans were taken in 18 young males at rest and maximum voluntary contraction (MVC). Further, the ST was dissected and removed from its origins in 10 cadaveric specimens (5 cadavers). **Results** The cadaveric long arm of the TI was  $6.67 \pm 0.64$  cm ( $6.45 \pm 1.21$  cm in US) long while the shorter arm was  $2.39 \pm 0.38$  cm ( $1.99 \pm 0.75$  cm in US). The angle formed by the two TI arms ranged from  $53.19$  (US) to  $56.05^\circ$  (cadavers) while more superficial fascicles intersected the inscription at significantly higher angles (range  $31.98 \pm 6.15^\circ$  to  $34.69 \pm 7.71^\circ$ ) compared with deeper fascicles ( $p > 0.05$ ). Fascicle length did not differ between compartments, but it was significantly smaller in superficial layers compared with deeper layers ( $p < 0.05$ ). With the exception of the angle between the TI arm and the deep aponeurosis, all measured angles as well as the length of the long arm of the TI increased significantly from rest to MVC ( $p < 0.05$ ). **Discussion** The role of the TI probably lies in the local inter-connections with the fascicles of either compartment, which upon contraction, is such that ST muscle contracts as one muscle. However, the TI arm morphology changes from rest to MVC, indicating a non-uniform displacement of the TI, mainly between the superficial and deeper layers of the muscle.

## TENDON STRAIN FOLLOWING YEARS OF SYSTEMATIC STRETCHING

MOLTUBAKK, M., ERIKSRUD, O., PAULSEN, G., BOJSEN-MØLLER, J.

NORWEGIAN SCHOOL OF SPORT SCIENCES

**Introduction** Stretching is commonly used as a means of improving sports performance, reducing injury risk, and in rehabilitation (Doucette and Goble, 1992, Wilson et al., 1992, Woods et al., 2007), while evidence of such effects at best is limited. Longitudinal studies with stretching interventions of up to 8 wks have been performed, but the musculotendinous response to chronic stretching is not well understood (Weppeler and Magnusson, 2010). We had the opportunity to examine a unique group of elite gymnasts; thus the purpose of the present study is to report patellar tendon mechanical properties in this group. **Methods** Twenty four national team rhythmic gymnasts (GYM) were compared to 10 control subjects (CON). This abstract presents data from 8 GYM and 6 CON. GYM ( $17 \pm 1$  yrs) had undertaken  $10 \pm 2$  years of systematic stretching, while CON ( $18 \pm 1$  yrs) had been active in sports for  $11 \pm 4$  years, without systematic stretching. Maximal voluntary isometric knee extension force (MVC) was obtained at a knee joint angle of  $90^\circ$ . Tendon force was determined based on moment arm calculations (O'Brien et al., 2010). Patellar tendon length was obtained by ultrasonography at rest and during isometric knee extension. Tendon strain at 25 and 50% of MVC was determined. **Results** No difference in MVC tendon force was seen between groups (GYM  $3322 \pm 596$  N; CON  $3477 \pm 653$  N). Patellar tendon strain tended to be greater in CON compared to GYM ( $11.0 \pm 7.9\%$  vs  $6.4 \pm 7.7\%$  at 25% MVC,  $16.5 \pm 7.2\%$  vs  $10.5 \pm 8.4\%$  at 50% MVC) ( $p = 0.15$  and  $0.09$ ). **Discussion** Habitual stretching is believed to reduce the stiffness of force transmitting tissues (Taylor et al., 1990). The present study utilizes a unique group of subjects to provide new insights. At matched force levels, tendon strains were similar, if not lower, in GYM. This suggests that chronic stretching does not reduce tendon stiffness, and is in line with Kubo et al., 2002, who found no effect on tendon stiffness after 3 wks of stretching. It is possible that rigorous stretching imposes mechanical loads similar to those of strength training, with corresponding tendinous adaptations (Seynnes et al., 2009). In conclusion, tendon does not appear to contribute to increased knee joint ROM following chronic stretching. The large joint ROMs seen in gymnasts may relate to factors such as increased muscle length or intramuscular connective tissue adaptations. **References** Doucette SA, Goble E (1992). ## RESISTANCE TRAINING INCREASES TENDON STIFFNESS AND AFFECTS FORCE PRODUCTION CHARACTERISTICS IN PREPUBERTAL CHILDREN

WAUGH, C.M.1, KORFF, T.1, FATH, F.1, BLAZEVOICH, A.J.2

1BRUNEL UNIVERSITY, LONDON, UK; 2EDITH COWAN UNIVERSITY, PERTH, AUS.

Age-related increases in muscular strength occur as a result of normal muscular growth and can be enhanced by resistance training. As a result, tendons must adapt in order to transmit greater forces efficiently to the bone and to minimise the risk of tendon injury. In adults, tendon mechanical properties have been shown to adapt to chronic loading. Such increases are thought to influence the rate of muscular force production, in addition to training-induced increases in the rate of muscle activation. Here, we asked whether training-induced adaptations in tendon stiffness and muscle activation could be elicited in prepubertal children, and whether such changes would affect rapid force production. Eighteen prepubertal children (aged  $9.0 \pm 0.3$  years) were divided into control (non-training) and experimental (training) groups. The experimental group completed a twice-weekly resistance training intervention over a 10-week duration. Each training session was part of a class-based physical education lesson and consisted of 2-3 sets of 8-15 plantarflexion resistance efforts, performed on a recumbent calf raise machine. Achilles tendon stiffness (slope of the tendon force-elongation curve), Young's modulus, electromechanical delay (EMD; time between the onsets of muscle activity and force), rate of force development (RFD; slope of the force-time curve) and rate of EMG rise (RER; slope of the EMG-time curve) were measured during maximum isometric plantarflexion contractions before and after training. No time-dependent changes were found in any of the dependent variables in the control group. In the experimental group, tendon stiffness and Young's modulus increased significantly ( $\sim 35\%$  and  $\sim 34\%$ , respectively). Tendon CSA remained unchanged after training, thus increases in stiffness were attributed to microstructural changes of the tendon, reflected by increases Young's modulus. RFD and RER remained unchanged after training whilst EMD decreased significantly ( $\sim 13\%$ ); this decrease was greatest for those who had the greatest increase in tendon stiffness ( $r = 0.59$ ). The present data show that the Achilles tendon adapts in response to resistance training in prepubertal children. This adaptation is associated with a shorter time to transfer muscular forces to the skeleton but not the rate at which this force is produced. Such a change has the potential to influence movement performance. As RFD was not influenced by the changes in tendon stiffness, the mechanisms underpinning rapid force production in children appear to be different to those found in adults. These findings are a significant step towards a more holistic understanding of age-related differences in muscular force production characteristics.

### OP-PM06 Protein Synthesis

#### INFLUENCE OF WHEY PROTEIN DOSE ON MUSCLE PROTEIN SYNTHESIS FOLLOWING LEG RESISTANCE EXERCISE

JACKMAN, S.R., WITARD, O.C., BREEN, L., SELBY, A., SMITH, K., TIPTON, K.D.

UNIVERSITY OF BIRMINGHAM

**Purpose:** Protein ingestion following resistance exercise enhances the muscle protein synthetic response to a greater extent than exercise alone. However, there appears to be a limit to the rate of muscle protein synthesis (MPS) that can be attained. Amino acids not used to synthesize new proteins are simply oxidised. The optimal amount of whey protein to ingest following exercise to maximally stimulate MPS has not been determined. Moreover, the response of MPS to differing doses of whey protein following exercise in the fed state is unknown. Therefore the purpose of this study was to determine the response of MPS to differing amounts of whey protein ingested after resistance exercise performed in the post-prandial state. **Method:** Thirty resistance-trained males performed a bout of unilateral leg resistance exercise in a parallel designed study. Exercise consisted of 8 x 10 repetitions at 80% one repetition maximum on both leg press and leg extension machines. Each subject consumed a beverage containing either 20g (20WP) or 40g (40WP) of whey protein or a placebo (PLA) ~20 min post exercise. Exercise was performed 3h following consumption of a high protein (~30% energy) breakfast. Myofibrillar protein synthesis was measured over the 4h recovery period by a primed constant infusion of L-[ring-13C6]phenylalanine and muscle biopsies immediately after and 4h post resistance exercise. Arterialized blood samples were collected throughout the trial. Diet was controlled for two days prior to the infusion trial to match habitual energy intake and dietary composition. **Results:** Plasma amino acid concentrations did not change for PLA, but increased following protein ingestion (40WP>20WP>PLA;  $p<0.05$ ). Peak amino acid concentrations were observed between 0.25 and 0.5h post drink in 20WP and 0.75 to 1h post drink in 40WP. Amino acid levels remained elevated for 4h post drink ingestion in both 40WP and 20WP. FSR was significantly higher in 40WP ( $0.079\pm0.003\%/h$ ) by 51% and 20WP ( $0.074\pm0.005\%/h$ ) by 41% than PLA ( $0.053\pm0.005\%/h$ ), however there were no differences between 40WP and 20WP over the 4h recovery period. Area under the curve of urea production post-drink ingestion was significantly higher in 40WP ( $5\pm1 \mu\text{mol}/\text{min}/\text{kg}\cdot4h$ ) and 20WP ( $4\pm3 \mu\text{mol}/\text{min}/\text{kg}\cdot4h$ ) than PLA ( $-5\pm2 \mu\text{mol}/\text{min}/\text{kg}\cdot4h$ ). Insulin concentrations were significantly higher in 40WP than PLA at 0.5 and 1h post drink ingestion. Glucose concentrations were not different between conditions. **Conclusion:** Our results are the first to show that when exercise is performed 3h following food intake there is a limit to the rate of post-exercise MPS following protein ingestion. Whey protein ingestion above 20g does not provide any additional benefit to MPS. Funded by GlaxoSmithKline Nutritional Healthcare

#### SEX-BASED DIFFERENCES IN FED-STATE MYOFIBRILLAR PROTEIN SYNTHESIS AND ANABOLIC SIGNALLING EARLY AND 24 H AFTER RESISTANCE EXERCISE

WEST, D.W.D.1, BURD, N.A.1, COFFEY, V.G.2, CHURCHWARD-VENNE, T.A.1, MITCHELL, C.J.1, BAKER, S.K.1, HAWLEY, J.A.2, PHILLIPS, S.M.1

1: MCMASTER UNIVERSITY (HAMILTON, CANADA), 2: RMIT UNIVERSITY (MELBOURNE, AUSTRALIA)

**Introduction** Men and women achieve comparable skeletal muscle hypertrophy after resistance training (Hubal et al., 2005) despite markedly disparate testosterone concentrations both basally and after an acute bout of resistance exercise (Vingren et al., 2009). Our aim was to examine anabolic mechanisms in men and women by measuring myofibrillar protein synthesis (MPS) and anabolic signalling early (1-5 h) and late (24-28 h) in recovery after resistance exercise and protein feeding. **Methods** Eight men ( $20\pm1$  y, BMI =  $24.3\pm2.4 \text{ kg}\cdot\text{m}^{-2}$ ) and eight women ( $22\pm1.8$  y, BMI =  $23.0\pm1.9 \text{ kg}\cdot\text{m}^{-2}$ ) received a primed, constant infusion of L-[ring-13C6]phenylalanine to assess MPS. Following a single biopsy to measure resting MPS, participants performed 5 sets of leg press at ~10 repetition maximum and 3 sets of both knee extension and hamstring curl at ~12 repetition maximum. Participants consumed 25 g of whey protein immediately after exercise and at 26 h of recovery. Additional biopsies were obtained at 1, 3, 5, 24, 26, and 28 h post-exercise. **Results** Akt-Ser473 phosphorylation was elevated to a greater extent ( $P<0.01$ ) in men at 1 h post-exercise and returned to basal levels in both groups for the remaining biopsy time points. mTORser2448 phosphorylation was elevated in men and women at 1, 3 and 5 h post-exercise and at 28 h, following protein feeding; however, there was a main effect for sex (men > women,  $P<0.01$ ). Responses of MPS data ( $n=4$ ) showed similar basal synthesis rates and increases in men (124 and 94% at 1-5 and 26-28 h, respectively) and women (48 and 162% at 1-5 and 26-28 h, respectively) after resistance exercise and protein feeding. **Discussion** Our study is the first to examine the effects of resistance exercise and protein feeding on myofibrillar protein synthesis (MPS) and anabolic signalling in men and women at both early (1-5 h) and late recovery (24-28 h) time points. Akt-mTOR phosphorylation was elevated by resistance exercise and feeding in men and women, but to a greater extent in men. Differences in Akt-mTOR signalling may contribute to marked elevations in MPS early post-exercise in men. Interestingly, while the mechanisms are unclear, women showed pronounced elevations in MPS 24 h in recovery despite similar signalling responses to men. **References** Hubal MJ, Gordish-Dressman H, Thompson PD et al. #### INCREASED TIME UNDER TENSION DURING LOW-INTENSITY RESISTANCE EXERCISE STIMULATES A PROLONGED ELEVATION OF MYOFIBRILLAR PROTEIN SYNTHESIS AND P70S6K PHOSPHORYLATION

BURD, N.A., WEST, D.W.D., ANDREWS, R.J., HECTOR, A.J., BAKER, S.K., PHILLIPS, S.M.

MCMASTER UNIVERSITY

**Introduction** There are no data available on the influence of time under muscle tension during resistance exercise on acute responses of muscle anabolism. Thus, we aimed to determine if the time that loaded muscle is under tension (TUT) during low intensity resistance exercise affects the synthesis of myofibrillar and mitochondrial proteins and p70S6K phosphorylation. **Methods** Eight men ( $23\pm1$  y, BMI =  $26.5\pm1.0 \text{ kg}\cdot\text{m}^{-2}$ ) received a primed, constant infusion of L-[ring-13C6]phenylalanine and biopsies of the vastus lateralis were obtained during fasting conditions, 6 h, 24 h, and 30 h post-exercise. Participants performed 3 sets of unilateral knee extension exercise at 30% 1RM performed at either a slow TUT (6 s concentric and eccentric; SLOW) until voluntary failure or an external work-matched control TUT (1 s concentric and 1 s eccentric; CTL). After exercise, participants consumed 20 g of whey protein and at 24 h exercise recovery **Results** Exercise at SLOW and CTL were identical in the number of contractions performed for sets 1-3 (12, 7, and 3 repetitions, respectively). TUT was greater ( $P<0.05$ ) for all 3 sets in SLOW (3.3 min, 2 min, 1.5 min for sets 1-3) as compared to CTL (0.4 min, 0.2 min, 0.2 min for sets 1-3).

There was no acute stimulation of myofibrillar protein synthesis rates during 0-6 h recovery in either the SLOW or CTL conditions ( $P > 0.05$ ). However, at 24-30 h of recovery there was an increased rate of myofibrillar protein synthesis (~2.3 fold increase above fasted rates), but only in the SLOW condition ( $P < 0.001$ ) that was related to p70S6K phosphorylation ( $r = 0.42$ ,  $P = 0.02$ ). In addition, exercise-induced rates of mitochondrial protein synthesis were elevated by 114% above fasting rates during 0-6 h recovery only after the SLOW condition; however, during 24 - 30 h recovery both CTL (126%) and SLOW (175%) conditions were elevated above fasting rates (all  $P < 0.05$ ). Summary Our data demonstrate that low-intensity resistance exercise performed with a slow TUT mediates a carryover effect on p70S6K phosphorylation and the feeding-induced stimulation of muscle protein synthesis rates at ~24 h exercise recovery. These data are consistent with other data demonstrating an enhanced sensitivity of myofibrillar protein synthesis to protein feeding during 24 h exercise recovery after high or low intensity exercise performed until failure (Burd et al., 2011). Thus, resistance exercise stimulates muscle protein synthesis rates at times beyond the immediate acute exercise period. Work supported by NSERC. ### INTERACTION OF MUSCLE GLYCOGEN AVAILABILITY AND NUTRITION ON CELL SIGNALLING AND MYOFIBRILLAR PROTEIN SYNTHESIS FOLLOWING RESISTANCE EXERCISE

CAMERA, D.1, WEST, D.2, BURD, N.2, PHILLIPS, S.2, HAWLEY, J.1, COFFEY, V.1

1:MIT UNIVERSITY (MELBOURNE, AUSTRALIA); 2:MCMMASTER UNIVERSITY (HAMILTON, CANADA)

Introduction: Training with low muscle glycogen concentration can augment adaptation responses to endurance training but the effect of glycogen availability on anabolic signalling and protein synthesis in skeletal muscle following resistance exercise (REX) is unknown. Aim: To determine the effect of muscle glycogen availability and post-exercise nutrition on anabolic signalling and myofibrillar protein synthesis (MPS) during the early recovery period following REX. Methods: Sixteen men ( $22.7 \pm 0.9$  years; BMI =  $23.9 \pm 0.5$  kg/m<sup>2</sup>, values are mean  $\pm$  SEM) were randomly assigned to nutrient or placebo groups ( $n = 8$ /group). After 48 h diet and activity control, subjects reported to the laboratory the evening before an experimental trial and performed a glycogen-depletion protocol consisting of one-leg cycling to fatigue (LOW), while the other leg rested (NORM). After exercise, subjects consumed a low carbohydrate (CHO) meal. After an overnight fast, a primed, constant infusion of L-[ring-13C6] phenylalanine was commenced and then subjects completed 8 sets of 5 unilateral leg press repetitions at 80% one repetition maximum. Immediately after REX and 2 h later subjects consumed a 500 mL bolus of a protein/CHO beverage (20 g whey + 40 g maltodextrin) or placebo. Muscle biopsies from both legs (vastus lateralis) were taken at rest and at 1 and 4 h after REX. Results: The depletion protocol generated divergent muscle glycogen concentrations that were higher in the NORM than LOW leg in both nutrient and placebo groups ( $P < 0.05$ ). Muscle glycogen in LOW increased between 1 and 4 h post-exercise in the nutrient (~84 mmol/kg dw-1,  $P = 0.009$ ) but not placebo group. Phosphorylation of mTORSer2448 increased above rest at 1 and 4 h (~8-18 fold) in NORM and from rest to 1 h (~11 fold) in LOW in the nutrient group, but was only elevated from rest at 1 and 4 h post-exercise (~2-4 fold) in LOW with placebo. There were no differences between NORM and LOW legs at any time point. Nutrient ingestion stimulated a greater rise in MPS compared to placebo in both NORM (nutrient vs. rest:  $0.070 \pm 0.008$  vs.  $0.045 \pm 0.007$  %h<sup>-1</sup>,  $P < .05$ ) and LOW legs ( $0.068 \pm 0.006$  vs.  $0.049 \pm 0.006$  %h<sup>-1</sup>,  $P < .05$ ) during the 1-4 h recovery period, but were not different between NORM and LOW within nutrient or placebo groups. Conclusion: Our results indicate that commencing high-intensity REX with reduced muscle glycogen availability does not suppress anabolic signalling and subsequent rates of MPS, at least in the initial 4 h post-exercise recovery period. However, it remains plausible that the effects of undertaking REX in a low glycogen state may be manifest through muscle protein breakdown. This study was funded by the Australian Sports Commission.

### THE INFLUENCE OF CARBOHYDRATE-PROTEIN CO-INGESTION FOLLOWING ENDURANCE EXERCISE ON MYOFIBRILLAR AND MITOCHONDRIAL PROTEIN SYNTHESIS

BREEN, L., PHILP, A., WITARD, O.C., JACKMAN, S.R., SELBY, A., SMITH, K., RENNIE, M.J., BAAR, K., TIPTON, K.D.

MCMMASTER UNIVERSITY

Purpose: The aim of the present study was to determine mitochondrial and myofibrillar muscle protein synthesis (MPS) when carbohydrate (CHO) or carbohydrate plus protein (C+P) beverages were ingested following prolonged cycling exercise. The intracellular mechanisms thought to regulate MPS were also determined. Method: In a single-blind, cross-over study, 10 trained cyclists (age  $29 \pm 6$  yr,  $\text{O}_2\text{max}$   $66.5 \pm 5$  mL/kg-1 min-1) completed two trials in a randomized order. Subjects cycled for 90 min at  $\sim 77 \pm 1\%$   $\text{O}_2\text{max}$  before ingesting a CHO (25 g of carbohydrate) or C+P (25 g carbohydrate + 10 g whey protein, Lucozade Sport Recovery Powder, GlaxoSmithKline, Brentford, UK) beverage immediately and 30 min post-exercise. A primed constant infusion of L-[ring-13C6] phenylalanine began 1.5 h prior to exercise and continued until 4 h post-exercise. Muscle biopsy samples were obtained to determine myofibrillar and mitochondrial MPS and the phosphorylation of intracellular signalling proteins. Arterialized blood samples were obtained throughout the protocol. Results: Plasma amino acid, plasma urea and serum insulin concentrations increased following ingestion of C+P only. Myofibrillar protein synthesis was ~35% greater for C+P compared to CHO ( $0.087 \pm 0.007$  and  $0.057 \pm 0.006$  %h<sup>-1</sup>, respectively;  $P = 0.025$ ). Mitochondrial protein synthesis rates were similar for C+P and CHO. mTORSer2448 phosphorylation was greater for C+P compared to CHO at 4 h post-exercise ( $P < 0.05$ ). p70S6KThr389 phosphorylation increased at 4 h post-exercise for C+P ( $P < 0.05$ ), whilst eEF2Thr56 phosphorylation increased by ~40% at 4 h post-exercise for CHO only ( $P < 0.01$ ). Conclusions: The present study demonstrates that the ingestion of protein in addition to carbohydrate following prolonged cycling stimulates an increase in myofibrillar, but not mitochondrial, MPS. These data indicate that the increase in myofibrillar MPS for C+P may be mediated through the phosphorylation of p70S6K, downstream of mTOR, which in turn may release the inhibition of eEF2 on mRNA translation elongation.

### OP-PM13 Training and Testing: Cycling

#### THE EFFECTS OF PACING STRATEGY ON AEROBIC AND ANAEROBIC ENERGY PRODUCTION IN ELITE OARSMEN.

DONOVAN, T.I., REILLY, T.2, CABLE, T.N.2, MACLAREN, D.M.P.2

*\*GLYNDWR UNIVERSITY, WREXHAM, \*\*RISES, LIVERPOOL JOHN MOORES UNIVERSITY, LIVERPOOL.*

Purpose: Even pacing is considered to be the most efficient physiological strategy for activities similar in duration and intensity to rowing. However the profile for elite competitive races follows a pattern characterised by a fast start, a decrease in speed over the middle portion and a sprint finish (positive pacing = PP). The physiological consequences of a PP strategy are an increase in anaerobic energy contribution and metabolic acidosis which could impair performance. This study quantifies and compares the anaerobic and aerobic components of the most commonly used pacing strategy in rowing i.e. PP, calculated from the 2003 World Championship, against a negative (NP) and an even pacing (EP) strategy. Methods: To ascertain a baseline for pacing manipulation eight elite rowers completed a maximal 2-km time trial on a rowing ergometer. Following a 48 h rest they completed a test to volitional exhaustion, using 3-min intervals and 30W incremental stages (VO<sub>2</sub> max trial). Accumulate oxygen deficit (AOD) regression equations were calculated from four 10-min sub maximal trials. Two 10-min sub maximal trials, with 30-min rest, at 230W and 320W for heavyweight (HW >72.5kg) or 200W and 290W for lightweight rowers (LW <72.5kg) were performed 48 h following the VO<sub>2</sub> max trial. After 24h rest the rowers performed a further two 10 min trials at 260W and 290W for HW or 230W and 260W for LW. The rowers then performed three 1600m pacing trials, with 48h rest between. Pace was based on mean baseline 2-km speed and adjusted every 400m (PP = mean speed +3.64%; -0.64%; -1.72%; -1.27%; EP = mean 2-km time: NP = reverse of PP). During all rowing trials respiratory gas was measured breath-by-breath, heart rate and stroke-by-stroke power output were recorded and post-trial lactate was assessed. Results: Relative VO<sub>2</sub> consumption during EP was significantly higher than both PP (P=0.013) and NP (P=0.005). Furthermore, EP resulted in a significantly greater proportion of aerobic energy production 77.1% (+/-2.9) compared with both PP (67.2% +/-2.7) and NP (69.5% +/-3.7) during the 1600-m ergometer trial. The difference in VO<sub>2</sub> between EP and PP was initiated at 400-m (P=0.011), whereas the difference between EP and NP commenced at 800-m (P=0.008). There was a significant difference in post trial lactate between PP (9.96 +/-2.04 mmol.l<sup>-1</sup>) and NP (11.33 +/-2.77 mmol.l<sup>-1</sup>; P=0.028), but not for EP (10.94 +/-2.62 mmol.l<sup>-1</sup>). There was no difference in the heart rate during the three trials (P=0.236). Conclusion: Even pacing results in a greater aerobic contribution to energy production during the 1600m trial and therefore may be a more efficient pacing strategy than those commonly utilised in competitive rowing.

#### THE EFFECT OF AN EVEN PACING STRATEGY ON EXERCISE TOLERANCE IN WELL TRAINED CYCLISTS

THOMAS, K., STONE, M.R., THOMPSON, K.G., ST CLAIR GIBSON, A., ANSLEY, L.

*NORTHUMBRIA UNIVERSITY*

Introduction Numerous authors have suggested that an even-pacing strategy is optimal in events > 2 mins (Atkinson et al., 2003; Gordon, 2005). Few studies have tested this assertion for prolonged endurance events, and those that have do not provide support for an even-pace strategy (Ham & Knez, 2009; Lander et al., 2009). In contrast to this we (Thomas et al., 2009) found cyclists perception of effort during constant-load even-paced exercise was lower than when exercise was self-paced; though the constant load nature of the task might explain these findings. Accordingly, the aim of this study was to compare a self-paced exercise bout, an even paced exercise bout where the exercise intensity is imposed independent of cadence, and an even-paced exercise bout where a target intensity is prescribed but the actual intensity is free to vary. Methods Data collection for this study is ongoing. Eight well-trained male cyclists (VO<sub>2</sub>max mean (SD) = 4.79 (0.32) L/min) took part in a pilot study, completing a self-paced (SP) 20-km time trial (TT) followed by two time- and work-matched even-paced trials based on performance in SP. In one even-paced trial the power output was imposed independent of cadence, akin to a constant load assessment (EP-IMP). In the other even-paced trial the exercise intensity was free to vary, but participants were instructed to maintain a target power output equivalent to the mean power output attained in SP (EP-FTV). The order of EP trials was randomised. Results Mean 20-km TT power output was 276 ± 22 W. Of the 8 participants, 4 successfully completed both EV-IMP and EV-FTV trials (mean ± SD power 271 ± 20 and 270 ± 19 for EV-IMP and EV-FTV respectively). Four participants failed to complete the EV-IMP trial and were unable to successfully complete the EV-FTV trial at their SP average power output (280 ± 28 W in SP compared to 267 ± 32 W in EV-FTV). Discussion The preliminary results of the study suggest that an even-paced strategy might be less than optimal in well-trained cyclists, contradicting previous recommendations. The small sample size and variability in response means these results should be interpreted with caution, and further data collection is currently in progress to strengthen these conclusions and to elucidate the underpinning physiological mechanisms. #### PHYSIOLOGICAL RESPONSES DURING 1 H CONSTANT AND VARIABLE POWER CYCLING AND SUBSEQUENT SUBMAXIMAL RUNNING

ETXEBARRIA, N.

*LOUGHBOROUGH UNIVERSITY - UNIVERSITY OF CANBERRA*

Narora Etxebarria<sup>1,2,3</sup>, Julie E A Hunt<sup>2</sup>, Stephen A Ingham<sup>1</sup> and Richard A Ferguson<sup>2</sup> <sup>1</sup> English Institute of Sport, EIS Performance Centre, Loughborough University, United Kingdom. <sup>2</sup> School of Sport, Exercise and Health Sciences, Loughborough University, United Kingdom. <sup>3</sup> Faculty of Health, Sports Studies, University of Canberra, Australia. Introduction The diverse nature of Olympic distance triathlon race venues elicits a wide range of physiological demands in the cycle and run legs. In particular, variations in terrain and course profile, especially numerous narrow turns requiring acceleration and deceleration may have substantial effects on the power distribution profile during the cycle leg, and consequently on physiological responses during the subsequent run. We compared the effects of variable versus constant power output during a 1 h cycling bout on physiological responses to submaximal running and time to exhaustion. Methods Nine well-trained male triathletes (V̇O<sub>2</sub>peak 67.8 ± 3.5 ml.kg<sup>-1</sup>.min<sup>-1</sup>) undertook an incremental step-wise running test (range 11-18 km.h<sup>-1</sup>) trial under three conditions: one trial without (CONTROL) and two trials (culminating in a time to exhaustion) with prior exercise consisting of 1 h cycling at either variable (VAR) or constant (CON) power. VAR involved intermittent efforts with race-specific power

outputs between 40 and 140% of maximal aerobic power (MAP) while in CON subjects held a mean power of 65% of MAP. CON and VAR trials were also matched for pedal cadence. Heart rate (HR), expiratory ventilation ( $\dot{V}E$ ), pulmonary oxygen uptake ( $\dot{V}O_2$ ), blood lactate (Bla) and rating of perceived exertion (RPE) were measured in all trials. Results During cycling  $\dot{V}E$  ( $22 \pm 14\%$ ; mean  $90\% \pm$  confidence limits) and Bla ( $179 \pm 48\%$ ) were substantially higher in VAR compared with CON. At the start of the submaximal run, HR ( $7.2 \pm 5.2\%$ ), Bla ( $216 \pm 54\%$ ),  $\dot{V}E$  ( $20 \pm 15\%$ ) and RPE ( $19 \pm 11\%$ ), were substantially elevated after VAR cycling compared with the CONTROL run. These initial differences disappeared during the run when the workload reached  $\sim 70\% \dot{V}O_{2peak}$ . There was no substantial difference in time to exhaustion between the conditions (CON  $217 \pm 232$  sec; VAR  $186 \pm 261$  sec; mean  $\pm$  SD, difference between the means  $17 \pm 111\%$ ; mean  $\pm 90\%$  confidence limits). Discussion Variable power cycling at race-specific power outputs for 1 h induces higher physiological responses compared to constant power cycling. Although variable power cycling elicits a transient elevation in subsequent running physiological responses there is little effect on run time to exhaustion.

## NEURAL AND MUSCULAR ADJUSTMENTS FOLLOWING REPEATED CYCLING SPRINTS IN NEUTRAL AND MODERATELY HOT ENVIRONMENTS

GIRARD, O., BISHOP, D., RACINAIS, S.

ASPETAR - QATAR ORTHOPAEDIC AND SPORTS MEDICINE HOSPITAL

**Introduction** The intention of this study was to determine the effect of an exposure to a moderately hot environment on neural and muscular adjustments following repeated cycling sprints. **Methods** Twelve active participants performed 10, 6-s "all-out" sprints on a cycle ergometer, interspersed with 30 s of recovery, followed, after 6 min of passive recovery, by five 6-s sprints, again interspersed by 30 s of recovery in either a neutral ( $24^\circ\text{C}/30\%\text{rH}$ ) or a moderately hot ( $35^\circ\text{C}/40\%\text{rH}$ ) environment. Neuromuscular tests including motor nerve (MN) and transcranial magnetic (TMS) stimulations during brief (5 s) and sustained (30 s) isometric contractions of the knee extensors were performed before and after exercise. **Results** Irrespectively of the condition, maximal strength ( $-12\%$ ) and rate of force development ( $\sim -15$ - $26\%$ ) during brief contractions decreased ( $P < 0.001$ ) after exercise. Resting twitch amplitude declined ( $P < 0.001$ ) by 42% and 40% (MN and TMS, respectively), independently of the condition. Under fatigue, there were neither significant change in voluntary activation estimated both from MN ( $\sim 80\%$ ) or TMS ( $\sim 90\%$ ) nor changes in TMS-based responses (i.e. motor evoked potential amplitudes and silent period durations at 50, 75 and 100% MVC) responses during brief maximal contractions. Voluntary activation declined ( $P < 0.01$ ) during the sustained contraction in all conditions, but reductions were more pronounced ( $P < 0.05$ ) after exercise. **Conclusion** Maximal and rapid muscle force characteristics were acutely affected concurrently with substantial reductions in muscle contractility following the repetition of cycle sprints. Whereas the contribution of neural mechanisms was less evident, end-exercise neuromuscular adjustments were minimally affected by an exposure to a moderately hot environment.

### OP-PM10 Heat and Dehydration

#### MUSCLE AND CEREBRAL OXYGENATION DURING UNCOMPENSABLE HEAT STRESS EXERCISE

PÉRIARD, J.D., THOMPSON, M.W., CAILLAUD, C., QUARESIMA, V.

UNIVERSITY OF SYDNEY

**MUSCLE AND CEREBRAL OXYGENATION DURING UNCOMPENSABLE HEAT STRESS EXERCISE** Julien D. Périard<sup>1</sup>, Martin W. Thompson<sup>1</sup>, Corinne Caillaud<sup>1</sup> and Valentina Quaresima<sup>2</sup> 1: University of Sydney (Lidcombe, Australia), 2: University of L'Aquila (L'Aquila, Italy) **Introduction** Oxygenation patterns in the brain and locomotor muscles during prolonged exercise in the heat have been suggested to impair performance (Neary et al., 2001; Subudhi et al., 2009). The purpose of this study was to investigate the influence of thermal and cardiovascular strain on muscle and cerebral oxygenation patterns during moderate and intense exercise to exhaustion in the heat. **Methods** Using near-infrared spectroscopy, oxygenation was examined in eight subjects cycling to exhaustion in an uncompensable hot environment ( $40^\circ\text{C}$ , 50% RH) at 60% (H60%) and 75% (H75%)  $\dot{V}O_{2max}$ , and for 60 min in cool conditions ( $18^\circ\text{C}$ , 40% RH) at 60%  $\dot{V}O_{2max}$  (C60%). Prefrontal cortex and vastus lateralis oxygenation were measured along with heart rate, cardiac output and mean arterial pressure. Core and skin temperature and skin blood flow were also measured. **Results** Rectal temperature reached  $39.8^\circ\text{C}$  (H60%),  $39.3^\circ\text{C}$  (H75%) and  $38.2^\circ\text{C}$  (C60%). Muscle oxygen saturation declined with exercise intensity in the first 5 min and remained depressed in all trials. The decline was greater in H60% and H75% due to greater deoxygenation. Cerebral oxygen saturation in C60% was maintained after an initial decrease. Throughout H60% and H75% cerebral oxygen saturation declined and was highly correlated with cardiovascular adjustments ( $R^2 = 0.80$  to  $0.99$ ). Exhaustion under heat stress occurred  $>96\%$  of maximum heart rate and was accompanied by significant declines in stroke volume, cardiac output and mean arterial pressure. **Discussion** The significant deoxygenation in locomotor muscles during H75% and H60% appears to indicate a limitation in oxygen delivery, rather than an inability to utilize the available oxygen (Rupp & Perrey, 2008). Given that perfusion and oxygenation are directly related to neuronal activity, the decrease in prefrontal cortex oxygenation saturation during exercise in the heat may reduce central neural drive. However, cerebral deoxygenation does not exclusively limit exercise in normoxic conditions (Amann et al. 2007), and prefrontal cortical activity is associated with goal-oriented behaviour, which influences motivation (Miller & Cohen, 2001). Therefore, our findings indicate that fatigue in an uncompensable hot environment is associated with a significant deoxygenation and reduction in oxygen delivery to locomotor muscle, and a progressive reduction of oxygen saturation in the brain that may influence the will to continue exercising. **References** Amann M et al. #### COLD WATER IMMERSION RECOVERY FOLLOWING INTERMITTENT-SPRINT EXERCISE IN THE HEAT

POINTON, M., DUFFIELD, R., CANNON, J., MARINO, F.E.

CHARLES STURT UNIVERSITY

**Introduction** Implementation of cold water immersion (CWI) recovery has become increasingly popular in many professional sports, particularly following exercise in hot environmental conditions. To date, mechanisms for an ergogenic effect of CWI recovery following high-intensity, intermittent-sprint exercise in the heat remain equivocal. As such, this study examined the effects of CWI on recovery of

performance, physiological and neuromuscular function following simulated team-sport exercise in the heat. This investigation aimed to examine possible mechanisms responsible for previously reported beneficial effects of CWI recovery following exercise in the heat. Methods Ten male team-sport athletes performed two sessions of a 2x30-min intermittent-sprint protocol (ISE) in 32°C and 52% humidity, followed by a 20-min CWI recovery intervention or passive recovery (CONT) in a randomized, crossover design. The ISE involved a 15-m sprint every minute separated by bouts of hard-running, jogging and walking. Maximal voluntary isometric force (MVC) and voluntary activation (VA), ratings of perceived muscle soreness (MS) and blood markers for muscle damage (creatine kinase (CK), aspartate aminotransferase (AST) and c-reactive protein (CRP)) were measured pre- and post-exercise, and immediately post-recovery, 2-h and 24-h post-recovery. Physiological measures of core temperature (Tcore), heart rate (HR), lactate (La-) and perceptions of exertion, thermal strain and thirst were also recorded throughout exercise and at the aforementioned time points. Results Exercise in the heat resulted in a reduction in MVC and VA, with an increase in Tcore, La-, CK, AST and CRP ( $P < 0.05$ ). CWI enhanced the post-exercise rate of reduction in Tcore ( $1.43 \pm 0.36^\circ\text{C}$  CONT v  $1.66 \pm 0.48^\circ\text{C}$  CWI), HR and MS, whilst increasing post-recovery MVC and VA ( $P < 0.05$ ). A large trend for increased activation and peak twitch force of the right knee extensor was evident immediately and 2h post CWI recovery ( $P = 0.09$ - $20$ ;  $d = 0.8$ ). In contrast, 24-h post-recovery MVC and activation were significantly higher in CONT compared to CWI ( $P = 0.05$ ). Conclusion Following exercise in the heat, CWI accelerated the reduction in physiological and cardiovascular load and improved acute recovery of MVC. With an increase in Pt, VA and blunted rise in AST following CWI, improvements in acute MVC were potentially due to a complex interplay of peripheral and centrally-mediated mechanisms. However, despite improved acute recovery of MVC, CWI resulted in an attenuated MVC 24 h post-recovery. While positive acute effects of CWI recovery were present post-exercise, prolonged use of CWI recovery warrants further investigation to fully elucidate the effects of CWI recovery on muscle repair and adaptation.

## RELATIONSHIPS BETWEEN PEAK AND SELF-PACED EXERCISE IN THE HEAT

SCHLADER, Z.J., STANNARD, S.R., MUNDEL, T.

MASSEY UNIVERSITY

Reductions in peak oxygen uptake (VO<sub>2peak</sub>) and, in turn, a higher percentage of VO<sub>2peak</sub> (%VO<sub>2peak</sub>) at a given submaximal exercise intensity have been proposed as factors mediating voluntary reductions in exercise intensity in the heat. However, this hypothesis has not been tested. Thus, the purpose of this study was to describe and compare the cardio-respiratory outcomes of self-paced and peak exercise in the heat. Eleven physically active male subject's peak cardio-respiratory and self-paced exercise responses were measured in both hot (HOT,  $40.2 \pm 0.3^\circ\text{C}$ ) and moderate (MOD,  $20.4 \pm 0.7^\circ\text{C}$ ) conditions. The peak exercise bouts consisted of exhaustive incremental exercise, while during the self-paced exercise subjects completed as much work as possible in 30 min. At submaximal intensities (power outputs) during incremental exercise, oxygen uptake (VO<sub>2</sub>) was ~7% higher ( $P < 0.05$ ) in HOT than in MOD. VO<sub>2peak</sub> (MOD,  $4.64 \pm 0.83$  L/min; HOT,  $4.54 \pm 0.77$  L/min), peak cardiac output (Qpeak; MOD,  $33.9 \pm 3.4$  L/min; HOT,  $33.8 \pm 4.5$  L/min), and core temperatures (Tc; MOD,  $37.8 \pm 0.4^\circ\text{C}$ ; HOT,  $37.9 \pm 0.4^\circ\text{C}$ ) were similar ( $P > 0.05$ ) between conditions. However, peak heart rate (MOD,  $176 \pm 10$  bpm; HOT,  $183 \pm 7$  bpm) and skin temperatures (Tsk; MOD,  $31.2 \pm 1.5^\circ\text{C}$ ; HOT,  $36.6 \pm 0.6^\circ\text{C}$ ) were higher ( $P < 0.01$ ) in HOT. During self-paced exercise, total work completed (MOD,  $346.6 \pm 79.7$  kJ; HOT,  $271.5 \pm 58.4$  kJ), and thus mean power output (MOD,  $201 \pm 56$  kJ; HOT,  $154 \pm 33$  kJ), was lower ( $P < 0.01$ ) in HOT. VO<sub>2</sub> was similar ( $P > 0.05$ ) through 15 min after which it was lower ( $P < 0.05$ ) in HOT. Relative to MOD, this represented a higher ( $P < 0.05$ ) and lower ( $P < 0.05$ ) %VO<sub>2peak</sub> during the initial and later stages of exercise. Heart rate was elevated ( $P < 0.05$ ) in HOT between 10 and 20 min, after which it was similar ( $P > 0.05$ ). Mean arterial pressure was lower ( $P < 0.05$ ) in HOT following 20 min, while stroke volume was lower ( $P < 0.05$ ) in HOT at 30 min. Cardiac output was similar ( $P > 0.05$ ) throughout both trials (mean: MOD,  $31.6 \pm 6.6$  L/min; HOT,  $30.1 \pm 6.0$  L/min), and thus represented a similar ( $P > 0.05$ ) percentage of Qpeak. Tsk was higher ( $P < 0.001$ ) throughout in HOT (mean: MOD,  $32.4 \pm 1.1^\circ\text{C}$ ; HOT,  $37.3 \pm 0.4^\circ\text{C}$ ), but Tc was similar ( $P > 0.05$ ) in both conditions until 30 min, upon which it was higher ( $P < 0.05$ ) in HOT (final Tc: MOD,  $38.5 \pm 0.3^\circ\text{C}$ ; HOT,  $38.7 \pm 0.3^\circ\text{C}$ ). The perception of effort was similar ( $P < 0.05$ ) in both trials. These results support the proposal that in the heat any given exercise intensity elicits a higher % VO<sub>2peak</sub>. However, in the current paradigm, when only Tsk is elevated, voluntary reductions in exercise intensity were not associated with changes in Qpeak or VO<sub>2peak</sub>. Therefore, this higher % VO<sub>2peak</sub> in the heat appears related to increases in VO<sub>2</sub> at a given submaximal intensity.

## EFFECT OF DIURETIC-INDUCED DEHYDRATION ON PROLONGED RUNNING PERFORMANCE IN HOT AND COOL CONDITIONS

LER, H.Y.1,2,3, THOMPSON, M.W.1, RUELL, P.1

1:THE UNIVERSITY OF SYDNEY (AUSTRALIA), 2:UNIVERSITY OF MALAYA (MALAYSIA), 3:TUNKU ABDUL RAHMAN COLLEGE (MALAYSIA)

Introduction Prolonged exercise performance in hot condition challenges the cardiovascular and thermoregulatory systems in maintaining homeostasis. The imposition of mild dehydration (2-3% bodyweight deficit) is thought to exacerbate the circulatory and thermal strain. However, leading runners appear to be the most dehydrated in such conditions (Noakes et al., 2003). The aim of this study was to investigate the effects of hypohydration on prolonged running performance in hot and cool conditions. Methods Eight male runners (age:  $32.8 \pm 6.1$  yr; body mass, BM:  $72.2 \pm 6.5$  kg; height:  $177.9 \pm 9.3$  cm; VO<sub>2max</sub>:  $65.5 \pm 6.4$  mL/kg/min) undertook four 60 min bouts of treadmill running at 65% VO<sub>2max</sub> followed by 1% gradient increase every 3 min until volitional fatigue: 1) euhydrated in 20°C (E20); 2) dehydrated in 10°C (D10); 3) euhydrated in 35°C (E35) and 4) dehydrated in 35°C (D35). Lasix® (1 mg /kg BM) was used in D10 and D35 trials to induce ~3% BM deficit. Results Subjects reached their point of fatigue at ~95%, of HRmax ( $177 \pm 10$  beats/min) and rating of perceived exertion (RPE) was equally high in all trials ( $18.4 \pm 1.1$ ). Time to fatigue in the E20 ( $75.3 \pm 3.5$  min) and D10 ( $73.7 \pm 4.2$  min) trials was significantly longer ( $p < 0.05$ ) than the E35 ( $64.7 \pm 6.8$  min) and D35 ( $40.6 \pm 13.6$  min) trials. At 25-min of running, cardiac output in all trials was similar  $\sim 22.2 \pm 4.1$  L/min, while heart rate (HR) was ~23 and ~14 beats/min higher in D35 ( $p < 0.001$ ) and E35 ( $p < 0.05$ ) trials respectively, when compared with E20 and D10 ( $\sim 143$  beats/min) trials. Skin temperature (Tsk) was ~6°C lower in E20 and D10 trials, compared with E35 and D35 trials ( $p < 0.001$ ) at 25-min and at fatigue. Similarly, body core temperature (Tcore) was ~0.5°C lower in E20 and D10 trials compared with E35 and D35 trials ( $p < 0.05$ ) at 25-min but there was no significant difference between D35 ( $39.2 \pm 0.5^\circ\text{C}$ ) and D10 ( $38.8 \pm 0.4^\circ\text{C}$ ) trials at fatigue. Thirst sensation increased over time and was significantly higher in E35 and D35 trials, compared to E20 and D10 trials ( $p < 0.05$ ). Discussion Running performance in E35 and D35 trials was impaired, in association with elevated ambient temperature, but not hypohydration. This performance decrement was approximately 10-35 minutes less endurance time in E35 and D35 respectively and was further associated with a greater upward HR drift, elevated Tsk, and Tcore. Furthermore, mild dehydration did not have an adverse effect on the running performance in cool conditions. RPE was similar across all conditions despite thirst sensation being greater in the hot conditions. In conclusion mild dehydration did not adversely affect endurance performance in hot or cool conditions. References Noakes, T. & Maharam, L.G. (2003). Clin J Sport Med. 13, 309-318.

## SOLAR RADIATION CONTRIBUTES TO LATE-RACE HEAT GAIN DURING MASS-PARTICIPATION MARATHON RUNNING IN A WARM-HUMID ENVIRONMENT

COSNEFROY, A.1, LEE, J.K.W.2, LIM, C.L.2, ESTON, R.G.1, BYRNE, C.1

1: SHS (EXETER, UK), 2: DSO (REPUBLIC OF SINGAPORE)

Thermodynamic properties of the environment modulate the endogenous heat strain arising from exercise (Kenney, 1998). This study aimed to investigate the magnitude and temporal nature of thermal exchanges occurring during a mass-participation 42.2 km footrace held in a warm and humid environment. Nineteen (12 males and 7 females) recreational distance runners participating in the Singapore marathon volunteered to take part in this ethically-approved study. Comprehensive mathematical models (ISO, 2004; Parsons, 2003) were used to quantify sources of gain and loss in body heat content during the race from continuous measurements of running speed, skin temperature (T<sub>sk</sub>) and weather conditions, with pre- to post-race change in body mass corrected for dietary intakes/outputs taken as an index of sweating. Body core temperature (T<sub>c</sub>) was also recorded using an intestinal sensor ingested 6 to 8 h beforehand. Data were averaged at 4.2 km intervals (i.e. 10% of total race length) and single-factor analyses of variance with repeated measures were employed to investigate changes in all variables as a function of distance covered. All volunteers completed the race in a mean  $\pm$  SD time of 4 h 30 min  $\pm$  40 min. Wet bulb globe temperature averaged 25.3°C from start to finish (range: 23.4–31.8°C). Potential for body heat storage occurred as globe temperature increased ( $p < 0.05$ ) and dry heat loss decreased ( $p < 0.05$ ) following sunrise at 13.5  $\pm$  1.8 km. This eventually resulted in gradual and significant ( $p < 0.05$ ) elevations in T<sub>sk</sub> and T<sub>c</sub> being observed across 25.3–42.2 km and 29.5–42.2 km, respectively, despite concomitant declines ( $p < 0.05$ ) in running speed and metabolic heat production. Exogenous heat gain via radiation occurred from 25.3–29.5 km and increased significantly thereafter ( $p < 0.05$ ), reaching 87  $\pm$  22 W/m<sup>2</sup> in the last 4.2 km. Metabolic heat production averaged 388  $\pm$  45 W/m<sup>2</sup> before the first significant deceleration at 29.5–33.8 km and was reduced to 352  $\pm$  54 W/m<sup>2</sup> across the final split ( $p < 0.05$ ), whereas convective and evaporative heat losses amounted to 59  $\pm$  41 W/m<sup>2</sup> and 278  $\pm$  66 W/m<sup>2</sup>, respectively. T<sub>c</sub> at finish was 39.2  $\pm$  0.6 °C and corresponding T<sub>sk</sub> was 34.5  $\pm$  1.9 °C. These results illustrate that during marathon running in warm and humid conditions, body heat gain consecutive to increasing solar radiation can outweigh the decrease in metabolic heat production associated with 'hitting the wall', thereby contributing to the deterioration of thermal balance. ## THE EFFECT OF BEVERAGE TEMPERATURE ON THERMOREGULATION AND ENDURANCE PERFORMANCE IN THE HEAT

BURDON, C.1, JOHNSON, N.1, CHAPMAN, P.2, O'CONNOR, H.1

1 UNIVERSITY OF SYDNEY, 2 AUSTRALIAN CATHOLIC UNIVERSITY

Introduction Endurance exercise in the heat causes a rise in core body temperature and may influence the evolution of fatigue. Cooler beverage temperature may attenuate the rise in body temperature and improve endurance performance in the heat by generating a heat sink (Lee et al, 2008) or via oral sensory mechanisms (Mundel et al., 2010). The aim of this study was to investigate the effect of cool beverage consumption during exercise in the heat on thermoregulatory mechanisms. The effect of cool beverage consumption or mouthwash on endurance performance was also evaluated. Methods Seven male participants cycled at steady state (65% VO<sub>2peak</sub>) for 90 min (SS) followed by a 5 kJ per kg body mass time trial (TT) in 32°C and 40% relative humidity. Participants ingested 3.5 ml per kg body mass 7.4% carbohydrate electrolyte beverage every 15 min during SS at 37°C (CON) or -1°C (COLD). During SS of a trial, participants consumed CON and every 5 min rinsed a cold (-1°C) 30g ice puree in the mouth for 25 s and expectorated (WASH). Rectal temperature (Tr), skin temperature (T<sub>sk</sub>), skin blood flow (SBF), heart rate (HR) and changes in body mass were measured. Venous blood was sampled for vasoactive intestinal peptide (VIP) and plasma osmolality. Results Tr and HR were not significantly different between trials ( $p < 0.05$ ). Preliminary data show during SS, T<sub>sk</sub> and SBF were lower in COLD versus CON. Heat storage was lower in COLD (14.8 $\pm$ 10.1 W.min<sup>2</sup>) versus CON (21.5 $\pm$ 10.4 W.min<sup>2</sup>) however data currently underpowered therefore a significant difference could not be detected. Sweat rate during SS was higher in COLD (3.2 $\pm$ 0.4kg) versus WASH (3.0 $\pm$ 0.5kg) and CON (3.0 $\pm$ 0.3kg) but not significantly different. During TT, heat storage was significantly higher in COLD (77.6 $\pm$ 30.6 W.min<sup>2</sup>) versus CON (27.7 $\pm$ 38.9 W.min<sup>2</sup>,  $p=0.03$ ) but not WASH (48.2 $\pm$ 24.1 W.min<sup>2</sup>,  $p<0.05$ ). TT performance was improved in the COLD (18.9  $\pm$  1.2min) versus WASH (20.6 $\pm$ 1.4min,  $p=0.7$ ) and CON (21.6 $\pm$ 1.9min,  $p=0.03$ ). Blood serum analysis not yet completed. Discussion Cold beverage consumption had no effect on Tr, however SBF was decreased causing a concomitant decrease in T<sub>sk</sub> (Wimer et al., 1997). Reduced T<sub>sk</sub> gradient above ambient temperature allowed for greater sweat loss. This initially reduced heat storage and allowed for increased capacity during TT where participants worked at a higher intensity and improved performance. Performance was improved with WASH versus CON suggesting oral sensory mechanisms may exist. Research currently limited by lack of power however further data is being collected. ### OP-SH03 Physical Activity and Movement Skills

## ABILITIES OF CHILDREN GIFTED IN SPORTS ACCORDING TO PHYSICAL EDUCATION TEACHERS

PLATVOET, S., ELFERINK-GEMSER, M.T., VISSCHER, C.

HAN UNIVERSITY / UMCG - UNIVERSITY OF GRONINGEN

Abilities of children gifted in sports according to Physical Education teachers Platvoet, SWJ. 1, Elferink-Gemser, MT. 1,2 & Visscher, C.1,2 1: HAN (Nijmegen, The Netherlands) 2:UMCG, RuG (Groningen, The Netherlands) Introduction Bailey and Morley's Model of talent development in Physical Education (2006), derived from Gagné's DMGT (2000), recognizes the influence of nature and nurture and takes into account the dynamic and multidimensional features of sport talent (Vaeyens et al, 2008). However, the model does not have a detailed, explanatory theoretical rationale underpinning yet (Phillips et al 2010). The aim of this study is to identify those abilities that according to PE teachers characterize children 6-8 years of age gifted in sports. This age-band is considered appropriate to assess gifts (i.e., natural abilities) because specific sport training most often has not occurred yet (Van Rossum and Gagné, 2007). Methods 165 Dutch physical education (PE) teachers in primary education filled in a digital questionnaire about abilities of children gifted in sports. A principal compo-

nent analysis (PCA) was conducted on the 69 items with orthogonal rotation (varimax). Temporal stability of the questionnaire was examined by determining the relative and absolute test-retest reliability. Results The Kaiser-Meyer-Olkin measure verified the sampling adequacy and Bartlett's test of sphericity was  $\chi^2 (2080) = 5248, 52, p < .05$ . Seven factors were extracted which account for 50.4% of the variance. Based on their content the factors were labeled Psychological Ability, Ability to respond, Creativity, Psychomotor Ability, Self regulation, Interpersonal and Intellectual Ability. All subscales had sufficient internal consistency (Cronbach's  $\alpha = .74$  to  $.84$ ) and relative temporal stability (ICC's  $.51$  -  $.86$ ), except the creativity scale. The mean differences between both measurements were non-significant ( $p < .05$ ) for each subscales except for IQ, indicating sufficient absolute reliability. Discussion According to PE teachers a child gifted in sports is characterized by seven abilities. These abilities are a specification of the abilities in Bailey and Morley's model and can be used for talent detection in the setting of PE. A next step is to investigate the relative significance of each ability for talent identification and talent development for different kinds of sports. References Bailey, R. & Morley, D. (2006). ### **"IF THERE WASN'T THE TECHNOLOGY THEN I WOULD PROBABLY BE OUT EVERYDAY": A QUALITATIVE STUDY OF CHILDREN'S STRATEGIES TO REDUCE THEIR SCREEN VIEWING**

SEBIRE, S.J., JAGO, R., GORELY, P.J., HOYOS CILLERO, I., BIDDLE, S.J.H.

UNIVERSITY OF BRISTOL

Introduction Screen-viewing (SV) (i.e., watching television, playing computer/video games, or using a PC, laptop or handheld console) is central to the lives of European children and has been positively associated with poor physical and mental health. Previous strategies to reduce children's SV have been developed by adults or researchers. In this study the perceptions of British children aged 10-11 in reducing SV and their self-developed SV reduction strategies were explored. Methods Ten semi-structured focus groups (Mean duration = 44 minutes) were conducted with 55 10-11 year old children (30 girls, 25 boys) from diverse socio-economic backgrounds. Topics covered children's feelings about reducing their SV, their ideas of SV reduction strategies and who would be involved. Data were transcribed verbatim and analysed using Thematic Analysis. Results Three themes were developed: (1) Reaction to Reduction; (2) Reduction: What, when and what else instead? ; and (3) Strategies to reduce screen-viewing. A range of single and multi-SV types were reported and children combined TV, computers, consoles and handheld consoles demonstrating the complexity of contemporary SV. Participants largely reacted positively to the idea of reducing SV though thought doing so would be challenging due to enjoyment, SV habits and favourite TV programmes. A range of SV types were put forward as candidates for reduction and participants believed they would replace SV time with both physically active and non-screen sedentary behaviours. Participants suggested SV could most easily be reduced after school and suggested strategies based on the provision of alternative activities, facilities and clubs. Screen-viewing guidelines delivered by adults were not supported as a strategy but peer-led educational interventions were proposed. Unexpectedly, participants reported that the focus group itself encouraged self-reflection and could be a prompt to change behaviour. A number of parent-based strategies emerged such as using rewards, charts and time limits which involved parent-child collaboration were also suggested. Discussion Children appeared open to SV reduction and offered insights into the strategies that they endorse and therefore may respond to best. The findings can inform the development of interventions designed to reduce children's sedentary SV. Reference: Marshall SJ, Gorely T, Biddle SJ. (2006). J Adolesc, 29, 333-349.

### **ADAPTATION AND VALIDATION OF TEACHERS' KNOWLEDGE OF TEACHING AND TECHNOLOGY, TECHNOLOGY INTEGRATION SELF-EFFICACY AND OUTCOME EXPECTATIONS QUESTIONNAIRES FOR PRESERVICE PE TEACHERS**

SEMİZ, K., INCE, M.L.

MIDDLE EAST TECHNICAL UNIVERSITY

ADAPTATION AND VALIDATION OF TEACHERS' KNOWLEDGE OF TEACHING AND TECHNOLOGY, TECHNOLOGY INTEGRATION SELF-EFFICACY AND OUTCOME EXPECTATIONS QUESTIONNAIRES FOR PRESERVICE PE TEACHERS Semiz, K., Ince, M.L. METU (Ankara, Turkey) Introduction As rapid and continual developments in technology have been affecting the world of education, competency and integration of technology into the teaching have been expected from Physical Education (PE) teachers. However, there is very limited number of validated data collection tools to measure the related characteristics of PE teachers in the literature. The aim of this study was to adapt and examine the validity of Preservice Teachers' Knowledge of Teaching and Technology, Technology Integration Self-Efficacy and Outcome Expectations questionnaires for preservice PE teachers. Methods Preservice Teachers' Knowledge of Teaching and Technology (TPACK) (Schmidt et al, 2009) questionnaire was translated to Turkish by experts. The original survey has 58 items on 4 subject areas (Literature, Social Studies, Math, Science). When survey was modified for PE, number of items decreased to 37. Total number of seven subscales in the original questionnaire decreased to five subscales after modification. Technology Integration Self-Efficacy (TISE) (Niederhauser & Perkmen, 2010) (16 items) and Outcome Expectations (OE) (9 items) questionnaires which are available in Turkish is used for the validation study. The questionnaires were applied to third (N= 249) and fourth grade (N= 186) preservice PE teachers from nine different Universities of Turkey. Confirmatory Factor Analysis (CFA) was administrated with AMOS and Cronbach  $\alpha$  coefficients were calculated with PASW. Results Internal consistency coefficients of TPACK subscales were 0.85 for Technological Knowledge, 0.79 for Content Knowledge, 0.89 for Pedagogical Knowledge, 0.77 for Technological Pedagogical Knowledge, 0.85 for Technological Pedagogical Content Knowledge, and lastly 0.94 for the total TPACK Survey. TISE and OE questionnaires'  $\alpha$  values were 0.95 and 0.91, respectively. The fit indexes for TPACK,  $\Delta \chi^2 (760) = 392, p < .001$ , CFI (0.94), TLI (0.94) and RMSA (0.47), were good. Also for TISE, the values that  $\Delta \chi^2 (294) = 96, p < .001$ , CFI (0.96), TLI (0.95) and RMSA (0.69) were satisfying. When one of the item with low factor loadings was excluded from the model, the CFA findings for OE were acceptable as  $\Delta \chi^2 (46) = 14, p < .001$ , CFI (0.98), TLI (0.97) and RMSA (0.72). Discussion On the basis of the findings, it is understood that the Turkish version of TPACK, TISE and OE questionnaires are valid and reliable for preservice PE teachers. They can be a powerful set of questionnaires for addressing an opportunity for future studies. References Niederhauser, D.S. & Perkmen, S. (2010). Beyond Self Efficacy : Measuring Preservice Teachers' Instructional Technology Outcome Expectations. Computers in Human Behavior 26, 436-442. Schmidt, D. et al (2009, April). ## FUNDAMENTAL MOVEMENT SKILL MASTERY IN SIX-YEAR-OLD PRE-SCHOOL CHILDREN

VANDAELE, B., COOLS, W., DE DECKER, S., DE MARTELAER, K.

FREE UNIVERSITY BRUSSELS (VUB)

Fundamental movement skill mastery in six-year-old pre-school children Vandaele, B (1,2), Cools, W (2), De Decker, S (1), De Martelaer Kristine (2) 1: Erasmus hogeschool Brussel, Departement of Teacher Training 2: Vrije Universiteit Brussel, Departement of Physical Education and Sports Training Introduction Growing evidence exists on low prevalence of fundamental movement skill (FMS) mastery of pre-school as well as of primary school children (Cools et al., 2009). Since motor proficiency is an important chain in a physical active lifestyle, the aim of this study was to examine the FMS mastery in 6 to 6 ½ year-old Flemish pre-school children. Methods Two hundred thirty six 6-year-old Flemish pre-school children (N=236) were individually assessed with the Motoriktest für Vier- bis Sechsjährige Kinder (MOT 4-6). Children's performances on 17 tasks were rated on a 3-point scale (0,1,2) and generated a Total Score (TS) of 34. Descriptive analyses were used to report frequencies and percentiles of scores. Tasks were grouped in four performance areas: Stability, Locomotion, Object control and Fine motor skills. Results Mean TS was 20.78 (SD= 5.7), without significant gender differences. A 2/2 score was obtained by more than 50% of the children in tasks of three different performance areas: stability (forward balance), fine motor skills (placing dots, grasping a tissue) and locomotion (passing through a hoop, height jump, turning jump). A 0/2 score was obtained by more than 30% of the Flemish pre-school children in tasks of two performance areas: stability (backward balance) and object control skills (throwing at a target, catching a ring). Discussion Although only few studies have explored FMS mastery at 6 years of age, results show similar trends as other studies (Okely, 2004). Considering the percentages of children in our study that perform poor on FMS, it is clear that on certain skills a lot of children still have difficulties at the age of 6. In general, prior attention should be paid to improvement of backward balance, throwing and catching skills. As object control skill proficiency, rather than locomotor skills, appear to be more crucial to predict PA in adolescence (Barnett, 2009), object control activities need to be more encouraged in early childhood. ## FUNDAMENTAL MOVEMENT SKILL PERFORMANCE IN RELATION TO SEX, WEIGHT, HEIGHT AND PHYSICAL ACTIVITIES IN PRESCHOOL CHILDREN

COOLS, W.1,3, DE MARTELAER, K.1,3, SAMAAY, C.1, ANDRIES, C.2.

1 VUB LK (BRUSSELS, BELGIUM) 2 VUB PE (BRUSSELS, BELGIUM), 3 VUB IDLO (BRUSSELS, BELGIUM)

Introduction As the development of fundamental movement skills is crucial to evolve a fit and healthy lifestyle, it is important to understand the factors related to this development. Therefore, the purpose of this study was to investigate gender differences in movement skill competence among 4 to 6-year-old preschool boys and girls and to investigate main effects of child specific characteristics (height, BMI and weight), past experiences (formal, informal and outdoor play activities) and socializing agents (siblings, pets) on their movement skill performance. Methods Subjects included 846 preschool children (471 boys, 375 girls) between 4 and 6 years of age. Children's FMS performance was assessed with the Motoriktest für Vier- bis Sechsjährige Kinder [MOT4-6]. Children's characteristics and physical activity (PA) were measured by self-administered parental surveys. A moderated multiple regression analysis was executed to investigate whether gender moderated the association between preschool children's movement skill performance and child individual factors. Results There were no significant differences in general movement skill and locomotor skill between boys and girls. Girls showed significantly better balance skill than boys ( $p < .01$ ) and boys showed significantly better object control skill than girls ( $p < .001$ ). Preschool children's higher movement skill was significantly predicted by a lower BMI z-score ( $p < .001$ ), by a higher height z-score ( $p < .001$ ), higher formal activity participation ( $p < .001$ ), higher outdoor play ( $p < .01$ ) and higher sports week participation ( $p < .01$ ). Additionally, lower pet interaction ( $p < .05$ ) significantly predicted higher locomotor skill in preschool children. The children's movement competence did not depend on the interaction between the child's gender and the entered child individual factors. Discussion This study has shown that 4 to 6-year-old preschool children's movement skill competence was positively correlated with growth, formal activities, outdoor play and sports week participation. The study also demonstrated that heavier children are less competent. Also gender differences appeared in children's movement skill competence. When organizing physical activities for children, it may be useful to offer different opportunities for boys and girls.

## THE ROLE OF THE COMMUNITY COACH IN ENABLING HEALTHFUL CHANGE THROUGH A PREMIER LEAGUE COMMUNITY FOOTBALL PROGRAMME

PARNELL, D., STRATTON, G., DRUST, B., RICHARDSON, D.

LIVERPOOL JOHN MOORES UNIVERSITY

Introduction There is little research attending to the working practices of Football in the Community (FitC) schemes and/or the role of the coaches that operate within them (Watson, 2000). The coach can play a significant developmental role within an individual's life (Wylleman, Alfermann, and Lavallee, 2004). This study examines the effectiveness of community coaches in enabling positive healthful changes. Methods The principles of ethnography guided the 1st author's fieldwork and observational engagement. This 10 month reconnaissance phase included a 16-week long community coaching initiative for primary school children (aged 7-11 years) (n=57). The 1st Author was immersed in the day-to-day working practices of the FitC scheme, (typically) 1-2 days per week. Informal data collection techniques were employed throughout (i.e., informal interactions) and recorded through a reflective diary and field notes. Participant focus groups were undertaken during and post initiative (week 8, n=10, week 16, n=10). Results Focus group data showed that most of the children were already 'active' and engaged in regular physical activity. The majority highlighted that the sessions provided fun and enjoyable experiences. Despite this the initiative experienced high attrition rates (54%). Some children alluded to negative memories relating to the coaches' practice. The 1st Author observed this practice and shared similar concerns, especially the absence of any healthful behaviour change message. Specifically coaches employed practices that in some cases failed to support or create a positive developmental environment relevant for the age and (football) ability of the participants. Coaches tended to adopt a performance oriented approach to their sessions. It became apparent that coaches were required to possess a minimum of a Football Association Level 2

Coaching Qualification (which has little or no health specific content). Discussion The adoption of a performance orientated approach and the absence of any healthful sentiments or behaviour change message limited the effectiveness of the initiative. However, the coaches did (usually) provide a fun and enjoyable experience. In order, to (explicitly) promote positive healthful change, coaches require a wider skill base. Specifically, skills that enable them to understand, translate and encourage positive healthful change within a variety of populations with varying levels of ability. References Watson, N. (2000). ##### PSYCHOLOGICAL CORRELATES OF GIRLS' PHYSICAL ACTIVITY LEVELS DURING MIXED-GENDER PHYSICAL EDUCATION LESSONS

SLINGERLAND, M., HAERENS, L., OOMEN, J., BORGHOUTS, L.B.

FONTYS UNIVERSITY OF APPLIED SCIENCES

Psychological Correlates of Girls' Physical Activity Levels During Mixed-Gender Physical Education Lessons Slingerland, M.1 Haerens, L.2, Oomen, J.1, Borghouts, L.B.1 1Fontys University of Applied Sciences (Tilburg, the Netherlands) 2Ghent University (Ghent, Belgium) Introduction To enhance the benefits of physical education in directly contributing to physical activity levels, maximal student involvement is imperative. However, adolescent girls have lower physical activity levels in PE than boys, mainly during competitive invasion games (Laurson et al., 2008; Slingerland et al. 2011). Starting from SDT as a theoretical framework, it was hypothesized that this gender difference might be related to differences in perceived competence, self-determined motivation, and perception of the learning climate. Methods Two-hundred-and-eighteen participants (127 boys, 89 girls, age 13,1 yrs. (SD=0.98) 11-15 yrs.) wore heart rate monitors during 25 minutes of an adapted 4 on 4 basketball gameplay in mixed-gender teams. After the gameplay-session students filled in validated questionnaires assessing their perception of the learning climate (competitive vs. non-competitive), perceived competence and self-determined motivation. All questionnaires were adapted to represent the basketball gameplay session students had just received. Percentage of time spent in moderate, vigorous and moderate-to-vigorous physical activity (MVPA) was calculated from the heart rate monitor data. T-tests were used for analyzing the data. Results Girls spent a lower percentage of time in MVPA compared to boys (64% versus 73%,  $t(214)=3.9$   $p<0.0001$ ), which was caused by a difference in vigorous activity (24% vs. 36%,  $t(214)=3.9$   $p<0.0001$ ) but not in moderate activity ( $t = -1.08$ , ns). Girls compared to boys perceived the learning climate as more competitive ( $t(214)=-2.388$   $p<0.05$ ), had lower perceived competence ( $t(214)= 6.845$   $p<0.0001$ ) and lower self-determined motivation ( $t(214)=2.243$   $p<0.05$ ). Discussion During mixed competitive gameplay girls perceive the learning climate as more competitive than boys. Also, they have lower perceived competence and have lower self-determined motivation compared to boys. This could explain the lower percentage of gameplay time in MVPA. However, further study is needed to determine the casual relationships. Nevertheless, PE programs that are dominated by competitive gameplay might need to be re-evaluated in terms of suitability for girls. References Laurson, K., Brown, D., Cullen, R. & Dennis, K. (2008) Heart rates of high school physical education students during team sports, individual sports, and fitness activities. Research Quarterly for Exercise and Sport, 79. ##### 'GO CLIMB A MOUNTAIN': THE ROLE OF USING OUTDOOR ADVENTURE ACTIVITIES IN SPORT PSYCHOLOGY INTERVENTIONS

RICHARDS, K.

LIVERPOOL JOHN MOORES UNIVERSITY

Outdoor adventure activities have a long history of application and practice in promoting psychological development and physical activity. They are often used, for example, to enhance mental well-being, promote psychological resilience, improve inter-personal relations and develop self-confidence. Sport psychologists have both capitalised on these benefits in their applied work (e.g. in the development of team cohesion) and have worked with some outdoor adventure sports (e.g. sailing). Also research has examined psychological characteristics of outdoor adventure athletes (e.g. mountaineers). However, there is limited research that examines the practical application of outdoor activities in wider sport psychology interventions, yet the growing psychotherapeutic application of outdoor adventure clearly indicates that these activities have a clinical application. Drawing upon applied research of developing outdoor adventure activities for psychotherapeutic interventions this paper will consider research and practice issues in the application of outdoor adventure activities in sport psychology (for example, the use of Interpersonal Process Recall as a research and practice strategy). This will be illustrated by examining psychological change processes in action of participants taking part in outdoor adventure interventions. In conclusion, the paper will raise critical questions about the future development of researching and using outdoor adventure activities for a range of athlete populations and psychological conditions.

##### WHAT IS THE IMPACT OF CHILDREN'S PHYSICAL EDUCATION FOR ASSURING DAILY PHYSICAL ACTIVITY RECOMMENDATIONS?

RODRIGUES, L.1,2, SOUSA, M.1,3

1: IPVC (PORTUGAL); 2: CIDESD (PORTUGAL); 3 ANTÓNIO FEUÓ BASIC SCHOOL (PONTE DE LIMA, PORTUGAL)

Introduction The benefits of regular physical activity (PA) for the health, fitness and behavior of school age children are major topics of discussion in the literature. International recommendations on this matter are for children to be physically active at least 60 minutes (1 hour), or to achieve a minimum of 12000 steps (girls) and 15000 steps (boys) each day. Since children attend school for a significant part

of their day, the expectation is that school time will have a major impact on their PA levels, and specifically that Physical Education (PE) time will significantly contribute to comply with the daily recommendations for every child. Methods A sample of 93 boys and 110 girls attending the 5th grade on a Portuguese school wore a pedometer (Silva Ex3 Connect) during five consecutive school days. BMI was used to classify each child according to IOTF cut-off values. Children self reported their participation on organized sports. A binary logistic regression was used to calculate the probability (odds ratio) for achieving the recommended number of steps on each day according to the existence of PE on that day. Results Results showed that during week days only 20% of the cases achieved the recommendations (23% for boys; 17% for girls), but when looking for school days with PE lessons (90 min or 45 min) we found a significant increase on the compliance. On a PE day, 41% and 21% (respectively on a 90 min and on a 45 min session day) of the children reached the recommended cut-off values; while on a regular (non PE) day, only 13% of the children achieved this outcome. Children on a PE day showed an odd ratio for complying with the recommendations respectively five (4.7) times higher (95%CI=3.2 to 6.8) on a 90 min PE day, and two (1.8) times higher (95%CI=1.2 to 2.8) on a 45 min PE day, comparing to a regular non PE day. This effect was independent of gender and weight status. As expected, the probability was even stronger when taking into account only children with no sports participation [8.7 (95%CI=4.7 to 13.1) for 90 min PE, and 2.6 (95%CI=1.4 to 4.7) for 45 min PE]; and remained significant for children with organized sports participation only for the 90 min PE days (2.8; 95%CI=1.5 to 5.0). Discussion Given the low percentage of children that achieve the recommended daily number of steps, it is imperative to promote opportunities for children to be more active. These results show evidence for the possible relevancy of a general approach to PA promotion based on school PE. Being the only mandatory moment were all children have the opportunity to be physically active, PE sessions showed a tremendous impact for the desirable maintenance of health related levels of PA.

### **PHYSICAL EDUCATION TEACHING AND ENERGY EXPENDITURE: A PILOT STUDY ON THE TEACHING COMPETENCES OF PRIMARY SCHOOL TEACHERS IN ITALY.**

AIELLO, P., SIBILIO, M.

UNIVERSITY OF SALERNO

International studies have showed that physical activities and sports for the development of healthy and effective motor habits in children of primary school can be supported by a professional teacher aware of the effects of used teaching methods (Carlomagno et al., 2010). The quality of physical activities and sports teaching is in fact influenced by well qualified teachers and the time devoted to them in the curriculum studies (Penney et al., 2009). The present pilot study addresses the need of evaluating as the lack of a specific formation of physical education teachers could negatively affect the didactics, realizing movement activities in which the intensity level does not correspond to the real intentions of the teacher. The research, conducted using as sample 176 students of primary school of Campania region (Italy), has required the following steps: • setting of a university-school working group made of researchers of the University of Salerno and teachers of primary school (6-11 aged students); • an integrated school-university plan ; • arrangement of an informative report to collect data on students; • training to teachers on the use of the portable multi sensor monitoring system; • request to the students to perform a physical activity of warm-up lasting 15 minutes; • collecting data of the caloric consumption of each student; As a calorimetric monitoring system was used the portable metabolic holter BodyMedia. In all classes it was found an average energy expenditure value greater than expected value in light physical activity of 15 minutes. In 6 classes out of 11 the average value was even higher than the expected value of 6 METs for moderate activities. The overall average (about 6 METs) was found to be almost twice the maximum expected (3 METs). The data collected highlighted the lack of teachers knowledge on the effects produced by their teaching methods, providing the possibility of a further deepening of the analysis of training needs of teachers that nowadays, in Italy, is still very weak in terms of methodology and assessment skills and not very interested in the physiological outcomes that contribute to the effectiveness of physical education teaching. ### **DEVELOPMENT AND INITIAL VALIDATION OF A PSYCHOMETRIC MEASURE OF CHILDREN'S WELL- AND ILL-BEING**

BRACEY, S.J., QUESTED, E., DUDA, J.L.

UNIVERSITY OF BIRMINGHAM

Well-being is a key outcome in research on the implications of an active lifestyle in variability of motivational processes in the physical activity domain. Yet there is a dearth of empirical work concerning physical activity and well-/ ill-being relationships with child populations and it is unclear if extant measures adequately capture children's conceptions of these experiences. Moreover, it is important to keep in mind that developmental differences are apparent within conceptualisations of such psychological constructs (Eys, et al., 2009). The aim of this research therefore was to develop and provide initial psychometric information on a multidimensional measure of children's well-and ill-being. Method Drawing from a qualitative study of children's concepts of well-/ill-being (Bracey, et al., 2010, Dec) and review of the literature, an initial item pool of 103 items was created. These items were deemed to reflect a number of emerging dimensions, e.g., vitality, lethargy. Next a rigorous process of content analyses was conducted following recommendations by Dunn et al. (1999). A panel of experts were asked to appraise the content and face validity of the scales. The items were categorised by the experts in terms of emerging sub-themes, then the extent to which they perceived the item to tap the identified construct was rated using a 5-point Likert scale (1=poor match to 5=excellent match). Analyses revealed a reduced item pool of 70 items measuring children's well- and ill-being. Further validation of the items will be conducted using an independent sample of youth team sport participants (N= 600, age 7-18 years). Exploratory and confirmatory factor analyses will be employed to test factorial validity and invariance of the scales using structural equation modelling (SEM). Results Preliminary analysis suggests the content and factor validity of the questionnaire is good. It is hypothesised that the proposed hierarchical measurement model will be supported with initial analyses supporting the predicted two high order dimensions and ten sub dimensions. Data from the CFA and analyses of reliability will be presented at the Congress. Discussion Children's perceptions of their well-and ill-being experiences in the physical activity domain hold important implications (e.g., attrition rates, overall health and development). It is hoped the emerging measure will be a useful tool in future research. References Bracey, S.J., Quested, E., & Duda, J.L. (2010, December). Children's conceptualisations of well- and ill-being. ### OP-PM11 Training and Testing

#### ADDITIONAL ENDURANCE TRAINING SUPPRESSES THE EFFECT ON MAXIMAL FORCE PRODUCTION OF SPRINT TRAINING IN RATS

FURRER, R.

RESEARCH INSTITUTE MOVE - FACULTY OF HUMAN MOVEMENT SCIENCES

Additional endurance training suppresses the effect on maximal force production of sprint training in rats R. Furrer<sup>1</sup>, R.T. Jaspers<sup>1</sup>, N. Bravenboer<sup>1</sup>, P. Lips<sup>1</sup>, A. de Haan<sup>1</sup>. <sup>1</sup> Research Institute MOVE, VU University Amsterdam, the Netherlands Introduction: Different types of mechanical loading induce different adaptations in muscle tissue. Resistance exercise (short powerful contractions) induces muscle hypertrophy and increased muscle strength whereas long duration low intensity exercise results in atrophy and increased endurance. A combination of the two types of loading, known as concurrent training, can cause conflicting situations at the molecular level (van Wessel et al., 2010). The aim of this study was to investigate whether improvement of functional performance and maximal muscle force as a result of sprint training is suppressed when endurance training is added (concurrent training). Methods: 28 female Wistar rats, 10 weeks of age, were assigned to the sprint (n=10), concurrent (n=10) or control (n=8) group. The rats were trained 5 days per week for 6 weeks on a treadmill. During the sprint training, the rats performed 10 sprints of 15 s at near maximal velocity. The training was progressive with increasing velocity and inclination of the treadmill to a maximum of 40%. In addition to the sprint training, the concurrent training group also performed progressive endurance training on the same day (8 hours rest between the two training sessions). Maximal sprint velocity at an inclination of 40% was tested every two weeks by sprints of 15 s starting at 36.6 m/min and increasing up to their maximal velocity. After completing the 6 weeks training period, maximal muscle force production of the gastrocnemius medialis muscle (GM) was measured in situ. Results: The maximal sprint velocity significantly increased (p=0.001) by 13.5%. There was no significant difference of the maximal velocity between the sprint and concurrent group (p=0.76). After 6 weeks of training the normalized maximal force production (Fmax) of the GM of respectively the sprint, concurrent and control group was 14.6 (±1.1) N, 13.9 (±0.9) N and 13.2 (±0.6) N. Fmax of the sprint group was 10.6% higher (p=0.015) than the control group, in contrast to the concurrent group which was not different from the control (p=0.30) nor the sprint group (p=0.50). Discussion: This study shows that sprint training significantly increases Fmax. The effect of the sprint training on Fmax is suppressed if additional endurance training is performed. Interestingly, despite the increase in Fmax, functional performance during the sprint test does not differ between the sprint and concurrent group. Further analyses at the molecular level will elucidate this issue. #### DIFFERENCE IN APONEUROSIS ELONGATION DURING ECCENTRIC CONTRACTIONS BETWEEN THE FIRST AND SECOND EXERCISE BOUTS OF THE ELBOW FLEXORS

LAU, W.-Y., BLAZEVICH, A., NEWTON, M., NOSAKA, K.

EDITH COWAN UNIVERSITY (AUSTRALIA)

DIFFERENCE IN APONEUROSIS ELONGATION DURING ECCENTRIC CONTRACTIONS BETWEEN THE FIRST AND SECOND EXERCISE BOUTS OF THE ELBOW FLEXORS Lau, W.-Y., Blazeovich, A., Newton, M., Nosaka, K. Edith Cowan University (Australia) Introduction Unaccustomed eccentric exercise induces muscle damage characterised by delayed onset of muscle soreness (DOMS) and loss of muscle strength, but a repeated bout of the same exercise within several weeks results in less muscle damage, which is known as the repeated bout effect (1). It has been documented that neural, mechanical and cellular adaptations are associated with the repeated bout effect, but the underlying mechanisms have not been fully understood (2). The present study tested the hypothesis that muscle-tendon behaviours would be different between bouts such that the elongation of the aponeurosis of biceps brachii during eccentric contractions would be smaller during the second than the first eccentric exercise bout. Methods Ten untrained men (21-39 y) performed two exercise bouts consisting of 10 sets of 6 maximal isokinetic (60°s<sup>-1</sup>) eccentric contractions of the elbow flexors with the non-dominant arm separated by 4 weeks. During each eccentric contraction, the elbow joint angle was forcibly extended from a flexed (120°) to a fully extended position (180°) under maximal activation. The movements of the biceps brachii aponeurosis were recorded by B-mode ultrasonography (Aloka SSD-a10, Japan), and the movement distance of the end point of the aponeurosis origin from the beginning to the end of each contraction was calculated. Maximal voluntary isometric contraction strength (MVC), range of motion (ROM) and muscle soreness (VAS) were measured before, immediately after, 1-7 days following exercise. Changes in the movement distance together with the torque from the first to the last set, and changes in MVC strength, ROM and VAS after exercise were compared between first and second bouts by a two-way repeated measures ANOVA. Results Compared with the first bout, changes in MVC, ROM and VAS were smaller (P<0.05) following the second bout, showing the typical repeated bout effect. During eccentric contractions, the aponeurosis origin was extended, and the average distance of the aponeurosis elongation increased (P<0.05) from the 1st set (8.2 ± 4.7 mm) to the 10th set (16.4 ± 4.7 mm) for the first bout; however, no significant increases were found for the second bout (1st set: 8.4 ± 3.9 mm, 10th set: 9.3 ± 3.1 mm). Discussion These results suggest that the reduced magnitude of muscle damage in the second exercise bout compared with the first bout is associated with the smaller length changes in the aponeurosis in the second bout. It is possible that muscle fibre length changes are smaller in the repeated bout than the initial bout, which reduced the strain to the muscle fibres, resulting in less muscle damage. Reference 1. ## TALENT IDENTIFICATION AMONG 14- TO 17-YEAR-OLD ELITE MALE SOCCER PLAYERS BASED ON PHYSIOLOGICAL CHARACTERISTICS

GONAUS, C., MÜLLER, E.

UNIVERSITY OF SALZBURG

**INTRODUCTION** Although talent identification has been a popular topic in science and soccer, there is no consensus whether future success can be predicted by physiological tests at an early age (Le Gall et al., 2010; Williams & Reilly, 2000). For this reason, the purpose of the following study was to compare physiological characteristics among 14- to 17-year-old pre-selected soccer players in terms of subsequent career success. **METHOD** In 2001, the Austrian Football Association, the Department of Sport Science (University of Salzburg) and the IMSB (Vienna) launched a project targeting the development of talented soccer players who attended youth soccer academies throughout Austria. Since then, approximately 5,000 players ranging in age from 13 to 18 years were measured biannually in straight-line sprint (5, 10 and 20 m), 5 x 10 m line-to-line sprint (LL), hurdles agility run (AR), foot tapping (FT), counter movement jump (CMJ), drop jump (DJ), reaction test (RT), 2 kg standing medicine ball throw (MBT), sit and reach test (SR) and 20 m multi-stage endurance run (ER). 359 outfield players, ages 14 – 17, remained to be analyzed in a longitudinal design. Furthermore, these pre-selected academy players were retrospectively categorized based on whether they had been drafted into a youth national team (Under 18 to 21, n = 107) or not. The differences between Group (i.e. 'selected' vs. 'non-selected') and across Age (i.e. 14, 15, 16, 17 years) were analysed using a separate ANOVA for each variable. **RESULTS** The main effect for Age was significant ( $p < .01$ ) for all comparisons. A significant main effect for Group was found in LL,  $F(1, 336) = 11.34$ ,  $p < .01$ ,  $\eta^2 = .03$ ,  $(1-\beta) = .92$ , in AR,  $F(1, 313) = 6.72$ ,  $p = .01$ ,  $\eta^2 = .02$ ,  $(1-\beta) = .73$ , in CMJ,  $F(1, 341) = 6.52$ ,  $p = .01$ ,  $\eta^2 = .02$ ,  $(1-\beta) = .72$ , and in MBT,  $F(1, 340) = 16.34$ ,  $p < .01$ ,  $\eta^2 = .05$ ,  $(1-\beta) = .98$  in favour of selected players. Furthermore, a significant Group x Age interaction was observed displaying a greater increase for selected group in 5 m,  $F(3, 1050) = 4.77$ ,  $p < .01$ ,  $\eta^2 = .01$ ,  $(1-\beta) = .90$ , in 10 m,  $F(3, 1050) = 5.19$ ,  $p < .01$ ,  $\eta^2 = .02$ ,  $(1-\beta) = .93$ , in 20 m,  $F(3, 1050) = 4.75$ ,  $p < .01$ ,  $\eta^2 = .01$ ,  $(1-\beta) = .90$ , and in MBT,  $F(3, 1020) = 3.41$ ,  $p = .02$ ,  $\eta^2 = .01$ ,  $(1-\beta) = .77$ . **CONCLUSION** Regarding talent identification, we conclude that performance in soccer specific sprint tests (LL, AR), as well as in CMJ and in MBT at a young age has a small but crucial impact on future career success of elite soccer players. Concerning talent development, selected players showed higher improvements in straight-line sprint and in MBT during 5-year-academy-delay. Further research is needed to clarify these differences in development. Le Gall F, et al. (2010). J Sci Med Sport, 13, 90-95. Williams AM, Reilly T. (2000). J Sports Sci, 18, 657-667.

## THE CONTRIBUTION OF ANTHROPOMETRIC, PHYSICAL PERFORMANCE AND COORDINATIVE CHARACTERISTICS TO FEMALE GYMNASTICS TALENT IDENTIFICATION

VANDORPE, B.1, VANDENDRIESSCHE, J.1, VAEYENS, R.1, PION, J.1, LEFVRE, J.2, PHILIPPAERTS, R.1, LENOIR, M.1

1: GHENT UNIVERSITY; 2: KU LEUVEN

**Introduction** Traditional talent identification (TID) models in female gymnastics search for young gymnasts displaying characteristics for potential success by measuring their current performance on a multidimensional test battery (Régner et al., 1993). However, little is known about the contribution of those testing procedures in predicting the gymnasts' future success. This study aimed at identifying which variables are able to discriminate between elite and sub-elite gymnasts and contribute to performance in competition two years later. **Methods** In 2008, 33 young female competitive gymnasts aged 7-8 years completed a test battery measuring anthropometric, physical performance and coordinative characteristics. Based upon a technical evaluation by expert coaches, the gymnasts were assigned to an elite (N=19) or a sub-elite (N=14) group. In 2010, the all-around competition results of the 12 elite gymnasts effectively competing at the elite level two years later were obtained. Results MANCOVA with competitive level as fixed factor and age and maturity as covariates indicated that all gymnasts measured in 2008 portrayed a similar athletic build, but the elite-level gymnasts outperformed the less gifted gymnasts on all physical and coordinative variables. Linear regression analysis revealed that only a non-sport-specific motor coordination test of the 2008 test battery significantly contributed to the all-around result in competition two years later, with 38.7% of the variation in the competition score being explained by the result on that coordination test two years earlier. **Discussion** Competitive gymnasts exhibit a homogeneous anthropometric profile, which might be attributed to previous selection since growth and maturation are not largely affected by gymnastics training (Baxter-Jones et al., 2002). Likewise, although the physical performance characteristics were able to separate the two levels of gymnasts, these variables seemed to have low predictive value due to the possible synergic influence of training, growth and maturation (Vaeyens et al., 2008). It is likely that the anthropometric and physical performance variables will identify those gymnasts who dominate at the time of testing rather than those with potential to excel. In gymnastics, the early identification of gymnasts should take a motor coordination test into account as its discriminative and predictive power might be valuable for selection within a relatively homogeneous population of gymnasts exhibiting similar anthropometric and physical profiles. **References** Baxter-Jones AD, Thompson AM, Malina RM. ## NO EFFECTS OF ENDURANCE TRAINING ON SKELETAL MUSCLE FASCICLE ANGLE, ANATOMICAL CROSS-SECTIONAL AREA OR FIBER CROSS-SECTIONAL AREA

KJØLHEDE, T.1, FARUP, J.1, SØRENSEN, H.1, DALGAS, U.1, MØLLER, A.B.1, VESTERGAARD, P.F.1, RINGGAARD, S.2, BOJSEN-MØLLER, J.3, VISSING, K.1

1. AU (DENMARK), 2. MR-RC, AUH (DENMARK), 3. NRCTP, NIH (NORWAY)

**Introduction** Fascicle Angle (FA) is believed to increase as a result of fiber hypertrophy (2), and therefore associated with force generating capacity (3). FA has also been suggested as the explanatory link of the discrepancy observed in the relative adaptations in anatomical cross-sectional area (CSA) and fiber CSA following resistance training. However only one study has confirmed this in vivo (4). So far, no longitudinal studies have investigated the effect of endurance training on FA (1). The purpose of this study was therefore to investigate and compare the longitudinal effects of ten weeks of either progressive endurance or resistance training on FA, anatomical and fiber CSA and muscle strength. **Methods** 18 young untrained men were divided into an either endurance cycling (END) or resistance training (RT) group, with 7 subjects in each group completing the training period. Muscle morphological measures included assessment of m. vastus lateralis FA obtained by ultrasonography. Anatomical CSA was obtained by MRI of the total thigh (sum of extensor, flexor and adductor compartment). Fiber CSA was deduced from histochemical analyses of biopsy samples from m. vastus lateralis. Functional performance measures included VO2max, maximal voluntary contraction (MVC) of knee extensors and 3 repetition maximum (3RM) in knee extension (KE)

and leg press (LP). Results No changes in FA, anatomical or fiber CSA were observed for END after training. RT increased FA by  $23 \pm 8\%$  ( $p < 0.01$ ), anatomical CSA of the knee extensor muscles by  $9 \pm 3\%$  ( $p = 0.001$ ) and fiber CSA by  $19 \pm 7\%$  ( $p < 0.05$ ). END increased  $\dot{V}O_{2\max}$  by  $10 \pm 2\%$ . The RT group knee extensor MVC increased by  $19 \pm 5\%$  ( $p < 0.001$ ). RT increased 3RM in KE and LP ( $p < 0.001$ ), while END increased 3RM in LP ( $p < 0.001$ ). RT was significantly stronger than END post training in 3RM LP ( $p < 0.01$ ). Discussion 10 weeks of endurance cycling did not change FA, anatomical or fiber CSA. Nor was MVC increased. From the morphological adaptations in RT, it was validated that FA can serve as an explanatory link between the observed discrepancy between changes in anatomical and fiber CSA (4). The fact, that no increases in FA and fiber CSA were observed in response to endurance training, indirectly supports, that fiber hypertrophy and FA are interrelated. References 1. ## WHOLE-BODY CRYOTHERAPY ENHANCES MUSCULAR FORCE RECOVERY AFTER A TRAIL RUNNING

LOUIS, J., HAUSSWIRTH, C., POURNOT, H., BIEUZEN, F., BRISSWALTER, J.

UNIVERSITY NICE-SOPHIA ANTIPOLIS

WHOLE-BODY CRYOTHERAPY ENHANCES MUSCULAR FORCE RECOVERY AFTER A TRAIL RUNNING Louis J1,2, Hausswirth C2, Pournot H1,2, Bieuzen F2, Brisswalter J1 1Laboratory of human motricity, education and health, University of Nice-Sophia Antipolis, France 2Research department, National institute of sport, expertise, and performance (INSEP), Paris, France Introduction Eccentric contractions endured in downhill segments of trail running events are well known to procure severe structural damages in muscles, affecting their contractile and recuperative properties (Nicol et al. 2006). Therapies based on temperature changes are one of the most recent strategies proposed to enhance muscular recovery from such endurance efforts (Peiffer et al. 2009). Within this context, the purpose of this study was to test the efficacy of whole body cryotherapy (WBC), far infrared (FIR) or passive (PAS) modalities in enhancing muscular recovery within the 48 hours after a simulated trail running. Methods In 3 non-adjoint weeks, 9 well-trained runners (age:  $31.8 \pm 6.5$  years; body mass:  $70.6 \pm 6.5$  kg; height:  $1.79 \pm 0.06$  m; maximal oxygen uptake:  $62.0 \pm 3.9$  ml.min.kg<sup>-1</sup>) performed 3 repetitions of a simulated trail run on a motorized treadmill, in order to generate muscular fatigue. Immediately (post), post 24h, and post 48h after exercise, all participants tested three different recovery modalities (3min exposition to WBC at  $-110^{\circ}\text{C}$ , 30min exposition to FIR, 30min exposition to PAS) in a random order over the three separate weeks. Markers of muscle fatigue (maximal isometric muscle strength, plasma creatine kinase activity and perceived sensations) were recorded before, immediately after (post), post 1h, post 24h, and post 48h after exercise. Changes in studied variables over time and between recovery modalities were assessed by using a two way (period x recovery modality) analysis of variance. Results In all testing sessions, the simulated 48 min trail run induced a similar, significant amount of muscular fatigue. Maximal muscle strength and perceived sensations were recovered after the first WBC session (post 1h), while recovery took 24h with FIR, and was not attained through the PAS recovery modality. No differences in plasma CK concentrations were recorded between conditions. Conclusion Three WBC sessions performed within the 48 hours after a fatiguing running exercise accelerate muscular recovery to a greater extent than FIR or PAS modalities. #### LOWERING OF HEART RATE AFTER EXERCISE TRAINING IS ASSOCIATED WITH ADAPTATIONS IN SKELETAL MUSCLE: INSIGHT FROM HEART RATE PACING DURING TRAINED AND UNTRAINED MUSCLE EXERCISE

MORTENSEN, S.P.1, MØRKEBERG, J.1, SECHER, N.H.1, SVENDSEN, J.H.2, SALTIN, B.1

RIGSHOSPITALET

Introduction Exercise training is associated with a lowering of heart rate (HR) at the same workload. Generally, these adaptations are thought to be associated with adaptations in the central circulation. However, the signalling from contracting skeletal muscle (exercise pressor reflex) could also be dependent on the muscle training status. The aim of this study was to investigate the effect of exercise with a trained and untrained muscle on systemic and peripheral hemodynamics with and without atrial pacing. Methods 8 male subjects ( $24 \pm 2$  years,  $180 \pm 3$  cm,  $74 \pm 4$  kg,  $49 \pm 2$  mlO<sub>2</sub>/min/kg) were studied after 5 weeks of one-leg knee-extensor training (3-4 times/week) and 2 weeks of immobilization (full leg cast) of the other leg. Systemic and leg hemodynamics were measured during exercise with the: 1) untrained leg ( $19 \pm 2$ ,  $37 \pm 4$ ,  $56 \pm 5$ W), 2) trained leg ( $19 \pm 2$ ,  $37 \pm 4$ ,  $56 \pm 5$ ,  $74 \pm 7$ W) and 3) trained leg with HR pacing to untrained leg HR. Data were analyzed by repeated measures two-way ANOVA and Tukey's honestly significant difference (HSD) post hoc procedure. Results During exercise with the trained leg, HR was  $12 \pm 2$  (37W) and  $19 \pm 4$  (56W) beats/min lower than when exercise was performed with the untrained leg ( $P < 0.05$ ). However, cardiac output was similar because of a parallel change in stroke volume ( $P < 0.05$ ). MAP was lower during exercise with the trained leg ( $116 \pm 4$  mmHg (56W)) compared to the untrained leg ( $124 \pm 2$  mmHg), whereas there was no difference in central venous and pulmonary arterial pressures. Leg blood flow and plasma norepinephrine levels tended to be lower when exercise was performed with the trained leg compared to the untrained leg, whereas plasma epinephrine levels were similar. When HR was paced during exercise with the trained leg, cardiac output and leg blood flow remained unchanged, whereas stroke volume decreased ( $P < 0.05$ ) and blood pressures remained similar to control conditions. Discussion These results demonstrate that adaptations in skeletal muscle contribute to the lowering of HR after endurance training and indicate that there is a lowering of the sympathetic activation in trained muscle. The higher stroke volume after exercise training appears to be associated with an increased diastolic function and/or lowering of cardiac afterload.

#### CHANGES IN MYOELECTRICAL ACTIVITY AFTER PROLONGED MUSCLE DISUSE

SHUSHAKOV, V.1, MAASSEN, N.1, ZANGE, J.2

1: MEDICAL SCHOOL HANNOVER, 2: GERMAN AEROSPACE CENTER (DLR), COLOGNE

Introduction Strongly restricted muscle activity or complete immobilization result in decrease in muscle mass and force, i.e., muscle atrophy. In this study, we tested whether muscles excitability in the lower extremities is also affected through 21 day of inactivity during bed

rest (BR). As a control was used the activity in m. biceps brachii (BB). Methods Voluntary (EMG) and evoked (m-wave) muscle activity were recorded in 8 subjects before BR, at the day after the BR as well as 5 days after the BR (REG) in m. gastrocnemius (GA), m. vastus lateralis (VL) and BB. Torque and EMG were measured during sets of 3 maximum isometric contraction at different angles. During breaks m-waves were excited. The rate of the muscle fatigability was tested in VL during sustained knee extension for 30 s at 50 % MVC. Results In VL the torque decreased after the BR by about 22 % from  $261 \pm 7$  to  $205 \pm 7$  Nm, ( $P < 0.05$ ) and partly recovered during REG to  $234 \pm 7$  Nm ( $P < 0.05$ ). The median power frequency of the EMG (MF) was lower after the BR ( $84 \pm 2$  vs.  $94 \pm 2$  Hz). The duration of the m-wave increased from  $20.1 \pm 0.2$  to  $20.8 \pm 0.2$  ms ( $P < 0.05$ ) after the BR. Both parameters did not recover during REG. Signs of muscle fatigability in VL were not different before and after the BR neither for the torque nor for myoelectrical parameters. In GA decrease in torque was about 14% ( $P < 0.05$ ), the MF was not different, the m-wave duration rose from  $13.5 \pm 0.3$  to  $14.6 \pm 0.3$  ms ( $P < 0.05$ ). There were no changes in torque and properties of electrical activity in BB. Discussion One of the reasons for the loss of muscle force due to disuse should be a decrease in the protein synthesis (1). Additionally, our data show that the decrease in force in postural muscles due to BR is accompanied by signs of decrease in the muscle excitability. Thus, muscle atrophy due to disuse apparently involves not only impairment of the contractile apparatus but also the loss of sarcolemmal excitability. ## EFFECTS AND MECHANISMS OF STRENGTH TRAINING IN CHILDREN

MUEHLBAUER, T.1, GOESELE, A.2, ROGGO, K.2, WISCHER, T.3, FISCHER, S.4, ZUERNY, C.4, GOLLHOFER, A.5, KRIEMLER, S.4, GRANACHER, U.1

1: FRIEDRICH-SCHILLER-UNIVERSITY JENA, 2: CROSSKLINIK BASEL, 3: MERIAN ISELIN BASEL, 4: UNIVERSITY OF BASEL, 5: UNIVERSITY OF FREIBURG

Introduction It has been demonstrated that strength training can be organized in children in a safe and effective way (Falk and Tenenbaum, 1996). However, there is limited data regarding its impact on muscle hypertrophy (Mersch and Stoboy, 1989). This study investigated the effects of a high-intensity strength training (HIS) conducted during physical education on knee extensor/flexor strength, counter-movement jumping height, postural control, soft lean mass, and muscle cross-sectional area (CSA) of the dominant leg in prepubertal children. Methods Thirty-two children (14 females, 18 males) participated in this study and were assigned to an intervention ( $n=17$ , age:  $9 \pm 1$  years, mass:  $31 \pm 5$  kg, height:  $133 \pm 4$  cm) or a control class ( $n=15$ , age:  $9 \pm 1$  years, mass:  $34 \pm 9$  kg, height:  $135 \pm 8$  cm). The intervention group participated in 10 weeks (two times per week) of progressive weight-machine based HIS (70-80% of the 1RM) integrated in physical education. Pre and post testings included the measurements of (a) peak torque of the knee extensors/flexors at  $60^\circ/\text{s}$  and  $180^\circ/\text{s}$  (Con-Trex MJ System), (b) counter-movement jumping height (SPSport), (c) postural sway (GKS 1000), (d) soft lean mass of the leg by bioelectrical impedance analysis (InBody 720), and (e) CSA (m. quadriceps) by magnetic resonance imaging (Philips Intera 1.5 Tesla scanner). Results A 2 (group: intervention, control)  $\times$  2 (test: pre post) analysis of variance with repeated measures on test revealed significant improvements in peak torque of knee extensors at  $60^\circ/\text{s}$  ( $p=0.01$ , +19% from pre to post testing) and  $180^\circ/\text{s}$  ( $p<0.01$ , +17%) as well as of the knee flexors at  $60^\circ/\text{s}$  ( $p=0.02$ , +13%) and  $180^\circ/\text{s}$  ( $p<0.01$ , +12%). However, HIS did not produce significant changes in counter-movement jumping height, postural sway, soft lean mass, and muscle CSA. Discussion Results of this study illustrate that 10 weeks of a progressive HIS conducted during physical education represents a feasible and safe training modality that produced marked improvements in peak torque of knee extensors/flexors but not in counter-movement jumping height in prepubertal children. This may imply a limited transfer to sports-related skills like jumping. Since no statistical significant changes in soft lean mass and muscle CSA of lower extremity muscles were detected. It is suggested that the observed strength gains were primarily caused by neural factors with hypertrophy playing a minor role. References Falk B, Tenenbaum G. (1996). Sports Med, 22(3), 176-186. ## PILOT STUDY INTO THE USE OF A REPEATED JUMP TEST FOR IN-FIELD ATHLETE MONITORING

JANSE DE JONGE, X.1.2, DE RUITER, C.J.2, LOCKIE, R.1

1 UNIVERSITY OF NEWCASTLE, AUSTRALIA; 2 RESEARCH INSTITUTE MOVE, VU UNIVERSITY AMSTERDAM, THE NETHERLANDS

Monitoring athlete responses to training load is important in optimising performance. A reliable test that is time-efficient and can be conducted in the field would prove valuable for coaches. Accelerometers can be used to detect landing and take-off during walking and jumping, and their miniaturisation coupled with wireless technology allows for in-field measurement. This pilot study explored the use of accelerometers for repeated jump tests as an in-field athlete monitoring tool. Ten female soccer players (age  $17 \pm 1$  yrs, height  $1.69 \pm 0.09$  m, weight  $59.9 \pm 5.6$  kg) were monitored for 15 sessions over five weeks after two weeks of testing familiarisation. Measures included pre-training POMS scales for vigour and fatigue, session-RPE and HR. A small 1000Hz wireless 3D accelerometer was strapped to the player's boot. Ten maximal repeated stiffness jumps were performed following warm-up (pre) and after training (post). Subjects jumped as high as possible, with minimal bending of the knees and minimal contact time. Contact and flight times were derived from the accelerometer data. The ratio of flight time over contact time was calculated and the average of the three best consecutive ratios was used as an indication of jump test performance. Energy index (vigour/fatigue) was calculated from the POMS data. Training load was estimated both as session-RPE  $\times$  duration and as summated-HR-load. The ratio between post and pre jump performance was also calculated. ICC for the jump ratio measured each Monday over 5 weeks was 0.89. The ratio showed a typical error (CV) of 5.9% (95% confidence limits 4.8–8.5%) and a change in the mean ranging from -4% to 3%. Correlations between variables were low, which is likely due to the small subject number in this pilot. One subject, however, reported a correlation of 0.75 between jump ratio and energy index, suggesting that she jumped well when feeling energetic. Another subject showed a correlation of -0.58 between post/pre ratio and summated-HR-load, implying that high training load may partly explain her decrease in jump ratio. Practice matches resulted in significant decreases in post/pre ratio of  $8 \pm 9\%$ , and in pre-training jump ratio of  $7 \pm 6\%$  on the next day. After two rest days a significant increase in jump ratio of  $8 \pm 8\%$  was found. It seems that high intensity activity resulted in both an acute and sustained decrease in jump ratio and rest was followed by a recovery in jump ratio. The repeated jump test appears to reflect the team's training response and has the potential to assist coaches in their team's preparation. The promising results of this pilot study warrant further research into the use of accelerometers in repeated jump tests as a time effective, in-field athlete monitoring tool.

## EFFECT OF IN-SEASON CONCURRENT SOCCER AND STRENGTH-TRAINING SEQUENCE ON MUSCLE STRENGTH AND MORPHOLOGY OF ELITE SOCCER PLAYERS

ENRIGHT, K.1,2, IGA, J.1,2, MORTON, J.2, DRUST, B.2

1) WOLVERHAMPTON WANDERERS FOOTBALL CLUB, WOLVERHAMPTON, ENGLAND. 2) RESEARCH INSTITUTE FOR SPORT AND EXERCISE SCIENCES, LIVERPOOL JOHN MOORES UNIVERSITY, LIVERPOOL, ENGLAND

**Introduction** Concurrent strength and aerobic training restricts muscular strength development (1). It is unclear how the organisation of concurrent training may influence muscle morphology in elite soccer players (2). Consequently, the aim of the present study was to investigate the effect of training organisation on the mediators of strength in elite soccer players. **Method & Results** Fifteen elite soccer players (mean  $\pm$  SD 17  $\pm$  1.8 yrs, stature, 1.82 m  $\pm$  0.06 m, body mass, 77.0  $\pm$  7.3 kg, V O<sub>2</sub> peak, 62.0  $\pm$  4.7 ml·kg<sup>-1</sup>·min<sup>-1</sup>) participated in this study. Participants completed 5 high intensity soccer-specific (HISS) and 2 strength sessions each week for 5 weeks. Strength sessions took place after a day of rest and either prior to (9am  $\pm$  15min; RT-AM, n = 8) or following (2pm  $\pm$  15min; RT-PM, n = 7) HISS training. Factorial ANOVA designs indicated significant interaction effects for training time on half-back squat (H-Bs) (RT-AM, 9.6%: RT-PM 19.6%; P = 0.001) thickness of the thigh (proximal) (P-MT), (RT-AM, 3.9%: RT-PM, 6.8% P = 0.05), fascicle angle of pennation (vastus lateralis) (AoP) (RT-AM, 17.6%: RT-PM 25.6%; P  $\leq$  0.05), 10m sprinting time (RT-AM, -0.1%: RT-PM, -6.0% P = 0.01) and quadriceps strength (60°-s-1 CONCENTRIC (CON)), RT-AM, -0.4%: RT-PM, 11.3%; 180°-s-1 CON; RT-AM, 2.5%: RT-PM, 12.9%; P = 0.038). Significant main effects for time were observed in H-Bs (P = 0.001); isometric loading rate (P = 0.016); isokinetic hamstring strength (60°-s-1 CON, RT-AM, 12.2%: RT-PM, 19.2%; 180°-s-1 CON, RT-AM, 9.5%: RT-PM, 11.2%; 120°-s-1 ECCENTRIC, RT-AM, 23.3%: RT-PM, 16.8%; P  $\leq$  0.05); jumping height (RT-AM, 8.1%: RT-PM, 4.4%; P = 0.002); P-MT and AoP (P  $\leq$  0.05). **Discussion** Five weeks of in-season strength training performed before or after HISS training significantly increased muscle size, structure, and performance of elite soccer players. The magnitudes of these improvements were significantly greater when participants engaged in strength training after HISS. It is postulated circadian rhythm factors (e.g. hormonal status and muscle temperature) and the acute variables which influence phosphorylation of signalling proteins (AMPK & mTOR activation and/or suppression) may account for optimised adaptation in RT-PM. **Conclusion** Strength training adaptations may be optimised when high intensity aerobic training precedes strength training in elite soccer players. **References** 1. Hawley, J. (2010). Appl. Physiol. Nutr. Metab. 34: 355–361. 2. Chtara, M. (2008) JSCR. 22: 1037-1045.

## EFFECTS OF STATIC AND DYNAMIC EXERCISE ON HUMAN SKELETAL MUSCLES: STUDY WITH DIFFUSION-WEIGHTED MAGNETIC RESONANCE IMAGING

YAMAUCHI, J.1,2, KINUGASA, R.3,4,2, YANAGISAWA, O.3

1: TOKYO METROPOLITAN UNIVERSITY, 2: FUTURE INSTITUTE FOR SPORT SCIENCES, 3: WASEDA UNIVERSITY, 4: RIKEN

**[Introduction]** We have been quantified the increased the water in skeletal muscle caused by exercise (exercise-induced edema) using magnetic resonance imaging (MRI) techniques (Kinugasa et al. 2006, Yanagisawa et al. 2004). Also, we have shown that the level of exercise-induced edema is related to the mode of exercise, static and dynamic exercises (Yamauchi 2008). Still, it still unknown this physiological mechanism. Therefore, the purpose of this study was to investigate the effect of static and dynamic exercises on micro-movement of water molecules in human skeletal muscles of lower leg, using diffusion-weighted MRI. **[Methods]** Seven healthy subjects (age, 24.4 $\pm$ 1.0 yr; height, 173.0 $\pm$ 3.6 cm; body mass, 70.6 $\pm$ 8.4 kg, mean $\pm$ S.D.) volunteered for this study. They were examined a lower leg before and immediately after static and dynamic plantar flexion exercise on a GE 1.5 Tesla MRI scanner with a quadrature knee coil. By using diffusion-weighted MRI techniques, the apparent diffusion coefficient (ADC) value of soleus (SOL), lateral gastrocnemius (LG), medial gastrocnemius (MG) muscles was calculated. Plantar flexion exercises were performed at 20% of maximum voluntary contraction (MVC) in both left and right legs by static and dynamic exercises, respectively. During plantar flexion exercises, subjects sat with their leg on a straighten (extended knee) position. Both static and dynamic exercises consisted of 6 sets of 30-second contractions with 10-second rest intervals between exercise bouts. The dynamic exercise was performed by repetitive contraction and relaxation with full range of motion at maximum efforts. In order to determine intensity of exercises, maximum isometric plantar flexion strength of the left and right leg was measured with a dynamometer. Data are presented as mean $\pm$ S.D. **[Results]** After dynamic exercises, ADC values of LG and MG increased significantly, and these increases represent 109.5 $\pm$ 8.3% (p<0.05) and 112.5 $\pm$ 8.2% (p<0.01) of pre-exercise values, respectively; however, ADC values of SOL did not change significantly. On the other hand, ADC values of all muscles did not change significantly after static exercises. Relative change in MG after dynamic exercise was significantly higher than that after static exercise (p<0.05). **[Discussion]** The higher ADC values of LG and MG after dynamic exercise indicate increases in motion of intramuscular water molecules. This suggests the higher both water diffusion and capillary perfusion in the exercised muscles, which may cause to increased interstitial and intracellular fluid volume, capillary volume and venous volume in type II muscle fiber tissues. **[Reference]** Kinugasa R. et al. ### OP-PM48 Physiology: Thermoregulation

#### SUCCESSFUL HEAT ACCLIMATION OF ELITE PARALYMPIC ATHLETES.

CASTLE, P.

UNIVERSITY OF BEDFORDSHIRE

Castle, P.1, Kularatne, P.2, Brewer, J.1, Mauger, A.R.1, Tuttle, J.1, Sculthorpe, N.1, Maxwell, N.3, Webborn, N.3. 1: University of Bedfordshire (UK). 2 : Disability Target Shooting Great Britain. 3: University of Brighton (UK). **Introduction** Athletes with spinal cord injury are at a greater risk of heat illness during exercise in the heat due to an inhibited thermoregulatory system that limits sweating (Webborn et al. 2005). In able body athletes, increased sweat rate and sensitivity are markers of successful heat acclimation (HA; Buono et al. 2009). Therefore, the aim of this study was to investigate the level of adaptation to eight days HA in elite athletes with spinal cord injury. **Methods** Five paralympic shooters (age 40.2  $\pm$  18 yr) with spinal cord injury (two T9/T10 complete; one C5/6 complete; one, T4 polio with no motor or sensory function; and one T6 spina bifida with no motor function) consented to take part in the study. Athletes completed seven days HA in an environmental chamber set at 33.4  $\pm$  0.6°C, 64.8  $\pm$  3.7 % relative humidity. Each HA session lasted 60 min and consisted of 20 min armcrank exercise at 50  $\pm$  5 W followed by passive rest or optional simulated shooting. Aural canal temperature (Taur), perceived ther-

mal comfort and RPE were measured at 5 minute intervals. On days 1 and 7 fingertip, blood samples were collected for analysis of Hematocrit and Hemoglobin for assessment of plasma volume. Sweat collection swabs were attached to the inferior, medial border of the trapezius muscle for assessment of sweat volume and content. Body mass was recorded by an under floor, force plate adapted for wheelchair use. Results Resting core temperature reduced from  $36.3 \pm 0.2^{\circ}\text{C}$  on day 1, to  $36.0 \pm 0.2^{\circ}\text{C}$  on day 7 ( $P < 0.05$ ). Mean Taur during the HA session on day 1 was  $37.2 \pm 0.2^{\circ}\text{C}$  and this reduced to  $36.7 \pm 0.3^{\circ}\text{C}$  on day 7 ( $P < 0.05$ ). Ratings of thermal comfort on day 1 were  $5.1 \pm 0.2$  units, and this reduced to  $4.5 \pm 0.4$  units on day 7 ( $P < 0.05$ ). Ratings of perceived exertion during the 20 min exercise bout on day 1 were  $12.6 \pm 1.9$  units, and this reduced to  $11.4 \pm 0.7$  units on day 7 ( $P < 0.05$ ). Plasma volume on Day 1 was  $55.5 \pm 5.1\%$  and this increased to  $57.0 \pm 6.0\%$  on day 7 ( $P < 0.05$ ). No sweat response or changes in body mass were observed. Discussion To our knowledge this is the first study to show successful HA of elite athletes with spinal cord injury. Although no sweat response was observed, plasma volume expansion occurred indicating a fluid retention adaptation (Francesconi et al. 1983) which lowered Taur, improved thermal comfort and RPE. Elite athletes with spinal cord injury can HA to reduce the risk of heat illness. References Buono MJ, Numan TR, Claros RM, Brodine SK, and Kolkhorst FW. ## EFFECT OF COLD WATER IMMERSION ON REPEAT CYCLING PERFORMANCE AND THERMOREGULATION IN THERMO-NEUTRAL CONDITIONS

VAILE, J.I, CHUNG, W.I, DAWSON, B.2

1. AUSTRALIAN INSTITUTE OF SPORT, DEPARTMENT OF PHYSIOLOGY 2. THE UNIVERSITY OF WESTERN AUSTRALIA, SCHOOL OF SPORTS SCIENCE, EXERCISE & HEALTH

Introduction Cold water immersion (CWI) is an effective recovery procedure between exercise bouts in hot conditions (Vaile et al., 2008 and 2010), but any effects on thermoregulation and performance in thermoneutral conditions remain to be investigated. The aim of this study was to assess the effect of CWI, active (ACT) and passive recovery (PAS) on thermoregulation and repeat cycling performance in cool conditions in trained male cyclists ( $n=12$ ). Methods In  $20^{\circ}\text{C}$  and 40% relative humidity, cyclists completed 6 trials, each separated by one week. Each trial consisted of a 30 min exercise task (EX1), then one of six 15 min recovery interventions (intermittent CWI in either  $10^{\circ}\text{C}$ ,  $15^{\circ}\text{C}$ ,  $20^{\circ}\text{C}$  water, continuous CWI in  $20^{\circ}\text{C}$  water, ACT or PAS), followed by 40 min rest recovery, before repeating the exercise task (EX 2). Exercise involved 15 min at 75% peak power output, then a 15 min time trial. Recovery effectiveness was assessed via changes in total work in EX 2 compared to EX 1. Core temperature (rectal) RPE, HR, La and thermal comfort were also recorded. Results Performance in EX2 was significantly lower ( $p<0.05$ ) after ACT when compared to all CWI interventions, but ACT was not different to PAS. After 40 min of rest, core temperatures were significantly lower after CWI 10, 15 and continuous CWI compared to ACT and PAS ( $p<0.05$ ), with these differences sustained during the warm up period prior to EX2. Midway through EX2, core temperature was significantly lower ( $p<0.05$ ) with all CWI interventions than after PAS, and also after ACT (CWI 10 and 15 only). At the end of EX2 only CWI 10 recorded a significantly lower core temperature than all other interventions. Heart rate, La and RPE were not different between any recovery interventions after EX1 and EX2, but La was significantly lower immediately after ACT and at the end of the 40min rest. Thermal comfort was not different for any recovery intervention at the end of EX1 and EX2, but between exercise bouts was generally significantly lower ( $p<0.05$ ) after CWI 10 and 15 compared to ACT and PAS. Discussion These results show that CWI, whether applied intermittently or continuously, can benefit repeat cycling performance in thermoneutral conditions and generally results in lower core temperature values and thermal sensation responses than either ACT or PAS recovery interventions. ## PASSIVE HYPERTHERMIA IMPOSES A LOAD ON COGNITIVE CAPACITY

GAOUA, N., HERRERA, C.I, RACINAIS, S.I, GRANTHAM, J.I, EL MASSIOUI, F.2

1. ASPETAR, QATAR ORTHOPAEDIC AND SPORTS MEDICINE HOSPITAL 2. LABORATOIRE (CHART) / UFR DE PSYCHOLOGIE, PARIS 8, FRANCE

Introduction: Passive hyperthermia limits complex cognitive task performance. These decrements occur when the total cognitive resources are insufficient for both the task and the thermal stress. EEG has been suggested to be the best tool to non-invasively measure cognitive load in real time. Aim: To investigate the neurophysiologic correlates of cognitive deficits during exposure to hot environmental conditions. Methods: To date 6 subjects performed a planning task with two levels of complexity (simple: OTS-4 and complex OTS-6) under hot (HOT:  $50^{\circ}\text{C}$ , 30% rH) and control (CON:  $24^{\circ}\text{C}$ , 30% rH) conditions. Subjective measures of thermal comfort (TC) and thermal sensation (TS) were recorded in each condition. Central (Tcore) and average skin (Tskin) temperatures were recorded prior to the cognitive testing by telemetric ingestible pills and patches. In each condition, testing started after a 10 min walk and 60 min of rest. EEG was recorded from the Fz electrode site with additional ground and linked ear references. Quantitative EEG was computed using Fast Fourier Transformation for activity in theta (4-8Hz), alpha-1 (8-10Hz), and alpha-2 (8-10Hz) bands. Results: Both Tskin (CON,  $31.7 \pm 0.63^{\circ}\text{C}$  vs. HOT,  $39.53 \pm 0.27^{\circ}\text{C}$ ) and Tcore (CON,  $36.92 \pm 0.22^{\circ}\text{C}$  vs. HOT,  $38.96 \pm 0.24^{\circ}\text{C}$ ) were higher in HOT than in CON (both,  $p<0.001$ ). Subjects felt hotter (TS) and less comfortable (TC) in HOT (both,  $P < 0.05$ ). No significant difference was observed in reaction times between conditions in both levels of OTS complexity. Accuracy on the OTS-4 task was comparable between conditions but was significantly reduced on the OTS-6 task in HOT ( $p<0.005$ ). There was a significant temp x task interaction in theta power; baseline theta in HOT ( $2.4 \pm 0.67$ ) was greater than in CON ( $1.8 \pm 0.28$ ,  $p<0.05$ ); therefore in CON only theta in OTS-6 ( $2.4 \pm 0.15$ ) was greater than theta in OTS-4 ( $1.9 \pm 0.28$ ,  $p<0.02$ ). Discussion: Given current theory on the role of theta oscillations during working memory tasks, the present data indicate that working memory capacity was at threshold prior task engagement during passive hyperthermia. Conclusion: The cognitive load imposed by passive hyperthermia limits performance on complex cognitive tasks.

## COLD WATER IMMERSION AUGMENTS THE EXERCISE-INDUCED EXPRESSION OF PGC-1 $\alpha$ IN HUMAN SKELETAL MUSCLE

JOO, C.H., MORTON, J., DRUST, B., CLOSE, G., JEONG, T.S., GREGSON, W.

LIVERPOOL JOHN MOORES UNIVERSITY

Introduction Cold water immersion (CWI) enhances post-exercise recovery (Vaile et al., 2007), however, the mechanisms underpinning these responses have yet to be elucidated. The expression of peroxisome proliferator-activated receptor  $\gamma$  co-activator-1  $\alpha$  (PGC-1 $\alpha$ ), a key regulator of mitochondrial biogenesis, is increased in animals following chronic whole body cooling (Puigserver et al., 1998). However, it

is currently unknown whether post-exercise CWI influences the expression of PGC-1 $\alpha$  in human skeletal muscle. The aim of the present study was to therefore test the hypothesis that post-exercise CWI increases PGC-1 $\alpha$  mRNA expression in human skeletal muscle following acute exercise. Methods Eight healthy males ( $25 \pm 4$  years) performed high-intensity interval running (8x3-min bouts at 90% VO<sub>2</sub>max interspersed with 3-min recovery) on two separate occasions in a counterbalanced randomised crossover design. On each occasion, subjects rested passively (CON) or undertook 10-min of CWI (80°C) immediately after exercise. Muscle biopsies (vastus lateralis), rectal, muscle and skin temperature were taken at regular intervals during the 3h recovery period. All data were analysed using a two-factor (condition x time) within participants general linear model (GLM). Results Rectal temperature was similar between conditions during the 3h recovery period ( $P=0.17$ ), however, reductions in thigh skin and muscle (CON,  $-3.0 \pm 0.9^{\circ}\text{C}$ ; CWI,  $-4.6 \pm 1.0^{\circ}\text{C}$ ) temperature were significantly greater in the CWI condition compared to CON ( $P<0.05$ ). PGC-1 $\alpha$  mRNA expression did not change immediately post-exercise under both conditions (CON,  $0.9 \pm 0.7$ ; CWI,  $1.0 \pm 0.5$  fold;  $P>0.05$ ). However, its expression was significantly increased 3h post-exercise under both conditions ( $P=0.01$ ) with greater expression observed in CWI ( $5.6 \pm 3.4$ -fold) compared to CON ( $3.3 \pm 2.6$ -fold;  $P<0.01$ ). Discussion Data indicate that post-exercise CWI augments the exercise-induced expression of PGC-1 $\alpha$  mRNA. These data suggest that post-exercise CWI immersion may enhance the upstream signaling pathways associated with mitochondrial biogenesis and as such, our data have practical applications for athletes wishing to maximise training adaptations. ## DEHYDRATION DURING WHOLE-BODY HEAT STRESS CONTRIBUTES TO SUBSEQUENT REDUCTIONS IN LOWER-BODY NEGATIVE PRESSURE TOLERANCE

LUCAS, R.A.1,1,2, GANIO, M.S.1,2, PEARSON, J.1,2, CRANDALL, C.G.1,2

1: INSTITUTE FOR EXERCISE AND ENVIRONMENT MEDICINE, TEXAS HEALTH PRESBYTERIAN HOSPITAL DALLAS

Introduction The independent effects of dehydration and heat stress on blood pressure control during simulated hemorrhage are unknown. This study tested the hypothesis that dehydration, which accompanies heat stress, further compromises the maintenance of blood pressure during a simulated hemorrhagic challenge via LBNP. Method Seven individuals ( $34 \pm 9$  y;  $77 \pm 4$  kg) completed two passive heat trials on two separate days (randomized) either with (infusion trial) or without (dehydration trial) intravenous infusion of heated Lactated Ringers solution sufficient to replace sweat loss. Hemorrhage was simulated via progressive LBNP to pre-syncope. LBNP tolerance was quantified with a cumulative stress index (CSI; sum of LBNP level x minutes at each level). Body core temperature (intestinal pill), mean middle cerebral artery blood velocity (MCAvmean, transcranial Doppler), arterial blood pressure (Finometer®) and end-tidal carbon dioxide (PETCO<sub>2</sub>, nasal cannula) were measured continuously throughout each trial. Blood samples were obtained before heating and just prior to LBNP to estimate relative changes in plasma volume during heat stress. Results The increase in body core temperature (infusion trial:  $1.4 \pm 0.2^{\circ}\text{C}$ ; dehydration trial:  $1.4 \pm 0.1^{\circ}\text{C}$ ) and whole-body sweat loss (infusion trial:  $1.8 \pm 0.6\%$ ; dehydration trial:  $1.6 \pm 0.4\%$  body mass deficit) were similar between trials ( $P>0.05$ ). Intravenous infusion ( $1.3 \pm 0.5$  L) prevented the reduction in plasma volume that occurred during the dehydration trial (infusion trial:  $+3.1 \pm 7.1\%$ ; dehydration trial:  $-6.5 \pm 5.5\%$ ,  $P=0.01$ ). LBNP tolerance during the dehydration trial ( $407 \pm 126$  CSI units) was lower compared to the infusion trial ( $641 \pm 64$  CSI units,  $P<0.01$ ). MCAvmean was equivalent between dehydration and infusion trials during heat stress immediately prior to LBNP and at presyncope. However, when dehydrated MCAvmean was  $\sim 10$  cm/s lower during the initial LBNP stages (e.g., 20 mm Hg LBNP, infusion trial:  $63 \pm 10$  cm/s; dehydration trial:  $53 \pm 10$  cm/s,  $P=0.02$ ). Heat and LBNP related changes in MAP and PETCO<sub>2</sub> were similar ( $P>0.05$ ) between the dehydration and infusion trials. Conclusion These data indicate that dehydration during heat stress initially lowers cerebral perfusion during a hemorrhagic challenge, reducing an individual's tolerance and therefore, increasing the likelihood of syncope. ### OP-PM31 Physical Activity: Adapted

#### RELATIONSHIP BETWEEN LEG MUSCLE STRENGTH, SPRINT POWER AND AEROBIC POWER OUTPUT IN ADULTS WITH CEREBRAL PALSY

JANSSEN, T.W.1,2, DALLMEIJER, A.J.1,3, EVERS, M.1, VAN DER LUIJT, P.1, VAN DER WOUDE, L.H.4, NIENHUIJS, K.N.2, DE GROOT, S.2,4

1: VU UNIVERSITY AMSTERDAM, 2: READE, CENTER FOR REHABILITATION AND RHEUMATOLOGY, AMSTERDAM, 3: VU UNIVERSITY MEDICAL CENTER, AMSTERDAM, 4: UNIVERSITY MEDICAL CENTER GRONINGEN

Introduction Adults with cerebral palsy (CP) are at risk for an inactive lifestyle and low fitness levels. However, given the nature of the physical disability, there is no reason to expect that persons with CP cannot benefit from a regular exercise program. Not much information is available about the physical capacity of adults with CP. In this group, maximal aerobic power might be limited by peripheral factors such as muscle strength. The relationship between muscle strength, sprint power and maximal power output may consequently be stronger than in individuals without CP. The purpose of the study, therefore, was to investigate whether the relationship between muscle strength of the lower extremities, sprint power and maximal power output during ergometer cycling in adults with CP is different from the relationships in adults without CP. Methods In this cross-sectional study, 20 adults with CP (18-49 yrs, GMFCS I (n=15) and II (n=5), unilateral (n=10) and bilateral CP (n=10)) and 24 individuals without CP (19-55 years) were tested in a rehabilitation center. Isometric and isokinetic knee extension strength, sprint power and maximal power output were determined using an isokinetic dynamometer, a Wingate cycling test and a graded exercise test on a bicycle ergometer, respectively. Regression analysis was used to investigate relationships between parameters in adults with and without CP. Results In the participants without CP the relationship between sprint power and isometric ( $R=0.53$ ) or isokinetic knee extension strength ( $R=0.45$ ) was weak. A moderate relationship was found between sprint power and maximal power output ( $R=0.60$ ). In contrast, a strong relationship was found in the group with CP between sprint power and isometric ( $R=0.79$ ) and isokinetic extension strength ( $R=0.81$ ) of the least impaired leg as well as between sprint power and maximal aerobic power output ( $R=0.98$ ). Discussion Stronger relationships were found between muscle strength and sprint power and between sprint power and maximal power output in adults with CP compared to adults without CP. These results suggest that in this population muscle strength might be the limiting factor for lower-extremities activities such as cycling. Acknowledgements This study was supported by the Dr. W.M. Phelps-Stichting voor Spastici.

## BIOMECHANICAL DIFFERENCES BETWEEN PUBERTAL MALES WITH MENTAL RETARDATION & NORMAL INTELLIGENCE QUOTIENT DURING LANDING

BASSA, E.1, HASSANI, A.1, KOTZAMANIDOU, M.1, FOTIADOU, E.1, PATIKAS, D.2

1: TEFAA-AUTH, (THESSALONIKI, GREECE), 2: TEFAA-AUTH, (SERRES, GREECE)/I

**Introduction** Studies in the past have shown that individuals with MR present low performance in physical conditioning and motor skills (Shephard 1994; Angelopoulou 1999). Landing from a height is a common everyday task that is poorly controlled in people with MR compared to nIQ population, leading to increased risk for falls and injuries. Despite of these there are no available data in the literature concerning the biomechanical and neuromuscular differentiations in people with MR. Therefore, purpose of this study was to examine the differences in kinetic, kinematic and electromyographic (EMG) properties in pubertal males with MR and with nIQ during landings. **Methods** Twenty six untrained pubertal males (mean age: 15,5y for both groups), 13 with nIQ and 13 with MR (mean IQ:  $55,6 \pm 11,2$ ) participated in the study. The kinematic data, vertical ground reaction force (vGRF) and surface EMG of the vastus lateralis (VL) and biceps femoris (BF) was recorded. vGRF was normalized to body weight and EMG activity to the maximum EMG during each landing trial. All subjects performed 6 landings from 20 cm height (3 for familiarization and 3 for evaluation which were averaged). Each trial was separately analyzed to the pre-activation and braking phase. T-test for independent groups was used for the statistical analysis with level of significance was set at  $p < 0.05$ . **Results** When comparing the MR with the nIQ group, the former expressed significantly greater vGRF ( $p < 0,05$ ) and significantly less knee flexion ( $p < 0,05$ ) during preactivation, at touchdown and at the deepest point (maximum knee flexion). Furthermore, the EMG activity was significantly smaller in the individuals with MR for both muscles and in both phases ( $p < 0,05$ ). **Discussion** The obtained findings indicate that individuals with MR showed reduced neuromuscular activation, lower knee flexion and higher vGRF during landing. This suggests that people with MR adopt a stiffer technique for landing which in long-term could increase the potential for injuries. This difference could be attributed to learning factors and it seems that the task of landing is more unfamiliar to individuals with MR. **References** Angelopoulou N, Tsimaras V, Christoulas K, Kokaridas D, & Mandroukas K (1999). ## MOTOR DEVELOPMENT AND THE RELATIONSHIP WITH EXECUTIVE FUNCTIONING IN CHILDREN WITH INTELLECTUAL DISABILITIES.

HARTMAN, E., WESTENDORP, M., VISSCHER, C.

CENTER FOR HUMAN MOVEMENT SCIENCES

**Introduction** Children with intellectual disabilities (ID) have problems with their motor performance which may be related to their higher-order cognitive functions, especially executive functioning (EF; Diamond et al., 2000). The developmental skill-learning gap hypothesis assumes that, as children with less motor proficiency grow older, the gap between them and their peers becomes wider (Wall, 2004). The aim of the present study was to model the development of motor performance of 7-12 year-old children with ID in comparison with norm scores. Secondly, we examined the possible relationship between motor performance and EF in these children. **Methods** From 2009 until 2011, 48 children with ID from a special-needs school (34 boys, 14 girls; age range 7-10 in the year of enrollment; IQ range=53-79) participated in a longitudinal study. Measurements with the Movement ABC-2 for children were taken annually for three consecutive years. In the second year, EF was assessed with the Tower of London (TOL; i.e. planning, problem solving, and decision making). Data were analyzed with SPSS and MLwiN. The development of the children's raw motor scores was examined by comparing the likelihood ratio test statistic of a model with and a model without age. Analogously, the development of the children's standard scores (for comparison with the normative sample) was examined. **Results** In the year of study enrollment, the children with ID had significantly more definite motor problems (manual dexterity: 79%; ball skills: 44%; balance skills: 67%) than the normative sample (5%). All raw motor performance scores of the children increased significantly with age ( $p < .05$ ). The analysis of the standard scores showed that the gap between the normative sample and the children with ID remained stable over time (manual dexterity,  $p = .317$ ; ball skills,  $p = .157$ ; balance skills,  $p = .221$ ). Significant partial correlations (controlling for age and sex) with medium effect sizes were found between the manual dexterity scores ( $r = .34$ ,  $p = .049$ ), the ball skill scores ( $r = .36$ ,  $p = .046$ ) and the TOL scores 1 year later. The correlation between balance skills and the TOL score did not reach significance. **Discussion** The consistent gap in motor performance between children with ID and their peers underscores the importance of early motor interventions in order to stimulate the motor and cognitive development in this vulnerable population. Diamond A. (2000). Close interrelation of motor development and cognitive development and of the cerebellum and prefrontal cortex. Child Dev, 71, 44-56. Wall AET. (2004). ## EFFECT OF A MOTOR SKILL PROGRAM ON THE BALL SKILLS OF CHILDREN IN DUTCH SPECIAL EDUCATION

WESTENDORP, M.

CENTER FOR HUMAN MOVEMENT SCIENCES

**Introduction** Well-developed gross motor skills are important, because they may boost children's participation in physical activities and sports (Wall, 2004) as well as their cognitive abilities (Piek et al., 2008). Children in special education (i.e. children with learning or intellectual disabilities) have poor gross motor skills compared to typically developing children (Westendorp et al., in press). The aim of the present study was to examine the effect of a 16-week motor skill program, based on Newell's constraints model, on the ball skills of these children. **Methods** The study population included 96 children (aged 7-11), divided in 6 classes from a primary special-needs school located in the northern Netherlands. The 6 classes were randomly assigned to the experimental (47 children) and the control group (49 children). The intervention consisted of 32 lessons, twice a week (35 min. per lesson), during 16 weeks. The experimental group performed different exercises focused on improving ball skills. Based on Newell's constraints model, the skills were practiced under different conditions with the manipulation of task factors, for example different distances to the basket and exercising alone or with two or more children. The control group attended regular physical education lessons. Pre- en post intervention motor scores were obtained for the experimental and control group using the TGMD-2. For statistical analysis, ANCOVAs with repeated measures with group as the between factor, the locomotor and ball skill scores at pre and posttest (time) as the within factors, and IQ as the covariate. **Results** A significant group by time interaction for the ball skills was found ( $F=18.261$ ,  $p=.000$ ). The experimental group had significantly better ball skills after the motor skill program compared to the control group. No group by time interaction was found for the locomotor skill scores ( $F=1.386$ ,  $p=.243$ ). **Discussion** This study shows that the ball skills of a heterogeneous group children in special education improved after motor skill training. Further analyses will reveal whether or not the motor program has effect on children's participation in physical activity and child-

ren's cognitive skills. References Piek JP, Dawson L, Smith LM, Gasson N (2008). ### THE EFFECT OF WHOLE BODY VIBRATION ON BALANCE AND WALKING SPEED IN ADULTS WITH LEARNING DISABILITIES - A PRELIMINARY STUDY

BARTLEY, J., FATOYE, F.

*NORTH LANCASHIRE PRIMARY CARE TRUST, UK*

The effect of whole body vibration on balance and walking speed in adults with learning disabilities - a preliminary study 1Jeff Bartley, PhD; 2Francis Fatoye, PhD 1Community Health Team, North Lancashire Primary CareTrust, UK 2Physiotherapy of Health Professions, Manchester Metropolitan University, Manchester, UK Jeff.bartley@northlancs.nhs.uk Introduction Impaired balance and walking ability are common features associated with learning disabilities. Whole body vibration (WBV) has been used to improve balance and walking speed. The effectiveness of WBV has not been reported in people with learning disabilities. This study investigated the effect of WBV on balance and walking speed in adults with learning disabilities. Methods Twelve adults with learning disabilities (mean age + SD = 43.92 + 9.6 years) participated in the study. Following approval from the Local Housing Scheme participants were randomly allocated into a WBV intervention group and a non WBV control group. WBV was performed on a Galileo Advanced Plus. Intervention took place at a day centre for people with learning disabilities in the North West of England. Twelve WBV sessions were performed at a frequency of 12 Hz for 7 minutes three times a week. Balance was examined with the Berg balance scale while walking speed was assessed using 6 minutes walk test. Independent and Mann-Whitney U t-tests analyses were performed to examine between group differences for the 6 minutes walk test and balance test respectively. Paired t and Wilcoxon signed rank tests were used to examine within group difference between pre and post intervention for the 6 minutes walk and balance tests respectively. Statistical significance was set at  $p < 0.05$ . Results There was no significant difference ( $p = 0.631$ ) in balance test and walking speed ( $p = 0.733$ ) between the control and experimental groups. In addition, there was no significant difference ( $p = 0.068$ ) in balance test before and after whole body vibration. However, there was a significant difference ( $p = 0.048$ ) in walking speed before and after whole body vibration. Discussion The results of this study showed that there was no significant difference in balance and walking speed between WBV and the control groups in adults with learning disabilities. However, it showed that walking speed improved following the use of WBV in adults with this condition. This finding therefore suggests that WBV may be a useful modality for improving gait speed in individuals with learning disabilities. The findings of the present study should be interpreted with caution due to small sample. References Sackley et al (2005) *Clin Rehabil*. Vol. 19:216-23 Palsbo et al (2011) *Disabil Rehabil*. ### AN INTERNET-BASED AT HOME TRAINING PROTOCOL ENHANCES MUSCLE STRENGTH AND LUNG FUNCTION IN MULTIPLE SCLEROSIS PATIENTS

TALLNER, A., MAEURER, M., PFEIFER, K.

*UNIVERSITY OF ERLANGEN-NÜRNBERG*

Background: Numerous studies have shown beneficial effects of exercise in Multiple Sclerosis patients. As shown recently (Motl et al. 2010) using internet technology might treat and supervise patients more economically and more individually than conventional interventions, but systematic studies are lacking. Objective: To assess the feasibility and effectiveness of an internet-based at home physical training protocol (e-Training) in MS patients (EDSS 0-4). Design/Methods: We present data from an ongoing randomized controlled trial (study duration 9/2009 - 9/2011, required sample size:  $n=102$ ). Patients are allocated to either control group (CG; no treatment) or training group (TG). The TG receives internet-based strength and endurance training: patients exercise at home and document their training sessions via internet. Training protocols are supervised and adjusted by sports therapists. Assessments at baseline and after 3 months of training include: Isometric muscle strength (trunk flexion/extension), aerobic capacity ( $VO_{2max}$ ), lung function (peak expiratory flow PEF), Quality of Life (HAQUAMS) and Fatigue (WEIMuS). Outcomes are analysed using MANOVA with the factors time (within-subjects) and group (between-subjects). Results: Until December 2010, 32 patients completed the intervention and were analysed (age  $42 \pm 8.5$ ; EDSS  $2.9 \pm 0.8$ ). Patients in the TG showed significant improvements in trunk flexion/extension compared to the CG (flexion (in Newtonmeter, T1/T2): TG  $79.0/84.7$ , CG  $85.2/79.8$ ,  $p = .038$ ; extension: TG  $151.8/170.4$ , CG  $150.5/146.7$ ,  $p = .049$ ). Lung function also increased significantly (PEF (l/sec, T1/T2): TG  $5.2/6.0$ , CG  $6.4/5.83$ ;  $p = .005$ ). Results for aerobic capacity, fatigue and quality of life were all in favour of TG but non-significant ( $p = .124$ ;  $p = .215$ ;  $p = .170$ ). Conclusions: Although we only analysed one third of the required sample size yet, we discovered significant intervention effects concerning lung function and muscle force, the latter similar in magnitude to conventional exercise interventions. We conclude that internet-based exercise interventions are feasible and effective to enhance the health status of MS patients.

#### EFFECTS OF AEROBIC TRAINING AND RESISTANCE TRAINING ON VISCERAL AND ECTOPIC FAT AS MEASURED BY MAGNETIC RESONANCE IMAGING IN SUBJECTS WITH TYPE 2 DIABETES

BACCHI, E.1, NEGRI, C.1, FACCIOLO, N.2, DI SARRA, D.1, TARPERRI, C.3, MILANESE, C.3, BARALDO, A.3, SCHENA, F.3, CEVESE, A.3, LANZA, M.3, MOGHETTI, P.1

*UNIVERSITY OF VERONA*

Introduction Non-alcoholic fatty liver disease is an independent predictor of incident cardiovascular events in type 2 diabetes patients (DM2). Previous studies evaluated the effects of aerobic and resistance training on glycaemic control in DM2 (Sigal, 2007), but there are no data comparing the effects of these different types of exercise on ectopic fat and visceral adipose tissue in these patients. Methods 38 DM2, 11 females and 27 males (mean $\pm$ SD: age  $56 \pm 7$  years, BMI  $29.4 \pm 4.6$  kg/m $^2$ , HbA1c  $7.3 \pm 0.7\%$ ) were randomized to aerobic (AER,

n=20) or to resistance (RES, n=20) training. In both groups exercise was performed 3 times weekly, for 4 months. The AER group exercised for 60 minutes at 60-65% heart rate reserve. The RES group performed 3 series of 8-10 repetitions of 8 different exercises on weight machines each session, at 70-80% 1RM. Before and after the intervention programs visceral adipose tissue (VAT) and fat accumulation in the liver were measured using Magnetic Resonance Imaging. In addition, the following were assessed: fat mass (FM, by DEXA Total Body), metabolic features, insulin sensitivity (by euglycemic hyperinsulinemic clamp), peak oxygen uptake (VO<sub>2peak</sub>), leg and arm muscle 1RM tests (leg extension, LE; and chest press, CP). Results The two groups had similar baseline characteristics. After 4 months of training HbA<sub>1c</sub> and triglycerides were significantly reduced in both groups. Changes in VO<sub>2peak</sub>, as well as in leg and arm strength showed significant differences between AER and RES groups (VO<sub>2peak</sub>\*kg<sup>-1</sup> 15±10 vs 8±10%, p=0.04; LE 4±11 vs 19±10%, p<0.0001; CP 4±8 vs 24±11%, p<0.0001). AER and RES groups showed similar changes in total fat mass (-2.2±1.7 vs -1.7±1.3 kg). VAT and fat accumulation in the liver were also reduced to a similar extent in the two groups (-58±68 vs -30±40 cm<sup>2</sup>, and -8±18 vs -9±18%, respectively). Insulin sensitivity was significantly increased in both groups (by 30% and 19%, respectively). In the whole population, the change in VAT negatively correlated with change in insulin sensitivity (r=0.39, p<0.05). Discussion These data show that aerobic and resistance exercise can exert beneficial effects on both visceral adipose tissue and fat accumulation in the liver in subjects with DM2, with attenuation of insulin resistance and improved metabolic features. ### EXERCISE FOR FATTY LIVER DISEASE: IMPACT ON VASCULAR HEALTH AND HEPATIC FAT

PUGH, C.J.A.1, JONES, H.1, SPRUNG, V.S.1, KEMP, G.J.2, IRWIN, A.3, ADAMS, V.L.2, CABLE, N.T.1, RICHARDSON, P.4, GREEN, D.J.1,5, CUTHBERTSON, D.J.3

*1RISER, LIMU, 2MARIARC, UNIVERSITY OF LIVERPOOL, 3DEPARTMENT OF OBESITY AND ENDOCRINOLOGY, UHA, 4DEPARTMENT OF HEPATOLOGY, RLUH, UK, 5SCHOOL OF SPORTS SCIENCE, EXERCISE & HEALTH, UWA, AUS.*

Introduction Non-alcoholic fatty liver disease (NAFLD) is characterised by the accumulation of fat in the liver and is associated with liver-related morbidity and mortality. Nevertheless, the leading cause of death in these patients is cardiovascular disease (CVD). Flow mediated dilation (FMD) provides information regarding endothelial cell health and is an early marker of CVD which is directly linked to the risk of myocardial infarction. The efficacy of exercise training is poorly characterised in NAFLD patients and impacts on hepatic fat and vascular function have not previously been reported. We hypothesised FMD would be impaired in NAFLD and that exercise would reduce hepatic fat and improve FMD. Methods Eleven NAFLD patients and ten healthy controls volunteered. Whole body magnetic resonance imaging quantified visceral and subcutaneous fat and <sup>1</sup>H magnetic resonance spectroscopy determined hepatic fat. Brachial artery FMD, cardiorespiratory fitness and fasting glucose, lipids and alanine transaminase (ALT) were assessed in all subjects. All NAFLD patients underwent a 16-week supervised exercise intervention (moderate intensity, 30-45 min, 3-5 times per week) after which all assessments were repeated. Differences between NAFLD and controls, and the changes with exercise were analysed using t-tests. Data are presented as mean±SE. Results NAFLD and controls were matched for age (49±4 vs 46±3 yrs; P=0.50) and BMI (30±1 vs 29±1 kg/m<sup>2</sup>; P=0.50). FMD was impaired (5.2±0.8 vs 9.1±1.0%; P=0.01) and hepatic fat was elevated (22.3±5.1 vs 2.6±0.7%; P=0.003) in NAFLD patients, but abdominal subcutaneous fat did not differ. Overall hepatic fat decreased by 30% (22.3±5.1 vs 15.7±3.6%) and fitness improved by 29% (25.8±2.0 vs 33.3±2.9 ml.kg<sup>-1</sup>.min<sup>-1</sup>) following exercise in NAFLD (P<0.004). This was accompanied by a reduction in abdominal subcutaneous fat (8.0±0.8 vs 7.6±0.8 l; P=0.02) and improvement in FMD (5.2±0.8 vs 8.0±0.6%, P=0.002). ALT, BMI, body mass, hip and waist circumference all decreased with exercise (P<0.003). No changes were evident in lipid profiles, visceral or total subcutaneous fat. Discussion This is the first study to demonstrate the therapeutic effects of exercise training on hepatic fat and vascular health in NAFLD patients. Currently, there is no effective pharmacological treatment to decrease hepatic fat in this group at high risk of CVD. Therefore, these data strongly support the efficacy of exercise training as a leading preventive strategy in NAFLD.

### ACUTE EFFECT OF FATMAX EXERCISE ON GLYCAEMIA, INSULINAEMIA AND FAT OXIDATION IN OVERWEIGHT AND NON-OVERWEIGHT ADOLESCENT GIRLS

ZAKRZEWSKI, J.K., TOLFREY, K.

*LOUGHBOROUGH UNIVERSITY*

ACUTE EFFECT OF FATMAX EXERCISE ON GLYCAEMIA, INSULINAEMIA AND FAT OXIDATION IN OVERWEIGHT AND NON-OVERWEIGHT ADOLESCENT GIRLS Zakrzewski, J.K., Tolfrey, K. Loughborough University Introduction Exercise training at the intensity corresponding to maximal fat oxidation (Fatmax) increases insulin sensitivity and fat oxidation in obese adolescents (Ben Ounis et al. 2008). However, improvements in glycaemia, insulinaemia and fat oxidation the day after a single bout of exercise may occur in adults (Mitchell et al. 2008; Newsom et al. 2010). Findings from our laboratory indicate that postprandial glycaemia is particularly high following high glycaemic index (HGI) breakfast consumption in overweight adolescent girls, suggesting strategies to improve this response are required. The aim of the present study was to examine the acute effect of Fatmax exercise on glycaemia, insulinaemia and fat oxidation following a HGI breakfast in overweight and non-overweight adolescent girls. Methods Participants completed two 2-day trials in a counter-balanced order. On day 1, participants either performed 500 kcal of treadmill exercise at Fatmax (62(14) min at 61(8)% VO<sub>2peak</sub>) or rested. On day 2, a blood sample was taken in the fasted state and at 15, 30, 45, 60, 90 and 120 min following HGI breakfast consumption for the determination of blood glucose and plasma insulin. Fat oxidation was estimated in the fasted state and every 30 min during the postprandial period. Participants replicated their diet and minimised physical activity in the 48 h prior to main trials. Results Data for 10 girls (2 overweight, 8 non-overweight) are currently available for analysis. Postprandial absolute fat oxidation was higher the morning after Fatmax exercise compared with rest (P=0.026; ES: 0.66). Furthermore, both fasted (P=0.048; ES: 0.61) and postprandial (P=0.061; ES: 0.58) fat oxidation expressed as a percentage of total energy expenditure were higher the morning after Fatmax exercise. Blood glucose and plasma insulin concentrations will be analysed when the full sample is complete (n=24) to reduce inter-assay variation. Discussion Preliminary findings suggest fat oxidation is increased following Fatmax exercise performed ~16 h prior to HGI breakfast consumption in adolescent girls. This, along with potential benefits relating to glycaemia and insulinaemia, may have clinical relevance. The results from our complete study will allow an examination of these relationships in a larger group of ten overweight and fourteen non-overweight girls and to examine potential between-group differences. ## HIGH-FAT DIET OVERRULES THE EFFECTS OF TRAINING ON FIBER-SPECIFIC INTRAMYOCYELLULAR LIPID UTILIZATION DURING EXERCISE

VAN PROEYEN, K., SZLUFCHIK, K., NIELENS, H., VAN DYCK, R., RAMAEKERS, M., HESPEL, P.

KATHOLIEKE UNIVERSITEIT LEUVEN

**Introduction** Training in the fasted state can stimulate adaptations in muscle cells to facilitate energy production via fat oxidation (Van Proeyen et al., 2010; Van Proeyen et al., 2011; Stannard et al., 2010). Therefore, in this study we compared the effects of endurance training in the fasted state versus the fed state, on exercise-induced intramyocellular lipid (IMCL) and glycogen utilization during a 6-week period of hypercaloric fat-rich diet (HFD). **Methods** Healthy male volunteers (18-25 yrs) received hypercaloric (~+30% kcal/day) HFD (50% of kcal) in conjunction with endurance training (4 times 60-90 min per week) either in the fasted state (F; n=10), or with ample carbohydrate intake before and during exercise sessions (CHO; n=10). The control group (CON; n=7) received HFD without training and increased body weight by ~3kg (P<0.001) (Van Proeyen et al., 2010). Before and after HFD, the subjects performed a 2-hr constant-load bicycle exercise test in the fasted state at ~70% VO<sub>2</sub>max. **Results** HFD, both in the absence or presence of training (F or CHO), elevated basal IMCL content by ~50% in type I and by ~75% in type IIa fibers (P<0.05). Independent of training in F or CHO, HFD as such stimulated exercise-induced net IMCL breakdown by ~2-fold in type I and by ~4-fold in type IIa fibers. Furthermore, basal muscle glycogen level was well maintained and exercise-induced net glycogen breakdown was not significantly affected by HFD. **Conclusion** It is concluded that HFD, by increasing basal IMCL content, stimulates net IMCL degradation during exercise in type I, but even more in IIa fibers. This dietary effect even overrules the effects of training, independent of whether the training is performed in the fasted or the fed state. Furthermore, a HFD, which also provides adequate amounts of carbohydrates to preserve high muscle glycogen content during training, does not impair exercise-induced glycogen breakdown. **References** Stannard SR, Buckley AJ, Edge JA, & Thompson MW (2010). ## VISUALISATION OF ADIPOSE TRIGLYCERIDE LIPASE AND ITS ACTIVATOR CGI-58 IN HUMAN SKELETAL MUSCLE

CLARK, J.A., SHAW, C.S., WAGENMAKERS, A.J.M

UNIVERSITY OF BIRMINGHAM

**Introduction** Lipid droplets are present in skeletal muscle and the fatty acids liberated through lipolysis are utilised as a readily available fuel source during exercise in lean trained individuals. Adipose triglyceride lipase (ATGL) is responsible for the first step of lipolysis in human skeletal muscle; the removal of a FA from triacylglycerol to form diacylglycerol (DAG). Comparative gene identification-58 (CGI-58) is required for full activation of ATGL, increasing its activity up to 20 fold in a cultured kidney cell line however it is currently not known if, and under which conditions, it activates ATGL in human skeletal muscle. The aim of the present study was to develop immunofluorescence methodology to visualise ATGL and its activator CGI-58 in human skeletal muscle. This is the first time that CGI-58 has been visualised in sections of human skeletal muscle. **Methods** Percutaneous muscle biopsies were obtained from the vastus lateralis of 6 lean, physically active and insulin sensitive males. 5 µm cryosections were stained using antibodies targeting ATGL and CGI-58. Lipid droplets were stained using the neutral lipid dye oil red O and nuclei were stained using the DNA stain, DAPI. Images were viewed using wide-field fluorescence microscopy. **Results and Discussion** The acquired images reveal that neither ATGL nor CGI-58 colocalise fully with lipid droplets in human skeletal muscle. ATGL staining revealed a strong plasma membrane stain and a weak diffuse intracellular stain. CGI-58 showed diffuse intracellular staining with some more intense regions of staining in regions which colocalise with myonuclei. ATGL and CGI-58 partially colocalised, however neither ATGL nor CGI-58 colocalised with lipid droplets in the overnight fasted resting state. There was an intense staining of CGI-58 in the myonuclei suggesting that the protein either has an important role in the local DAG generation at this site or an alternative role in other metabolic processes. In future studies we will explore whether known lipolytic stimuli such as adrenaline and exercise and life-style interventions involving diet and exercise lead to a spatial redistribution of ATGL and CGI-58.

## ENHANCED INTRAMUSCULAR TRIGLYCERIDE METABOLISM AND IMPROVED INSULIN SENSITIVITY IN RESPONSE TO TRADITIONAL ENDURANCE AND HIGH INTENSITY INTERVAL TRAINING

SHEPHERD, S.O.1, COCKS, M.1, TIPTON, K.D.2, RANASINGHE, A.1, BARKER, T.1, WAGENMAKERS, A.J.M.1, SHAW, C.S.1

1: UNIVERSITY OF BIRMINGHAM (BIRMINGHAM, UK), 2: UNIVERSITY OF STIRLING (STIRLING, SCOTLAND)

Common adaptations to traditional endurance training (ET) are an increased mitochondrial density and a greater intramuscular triglyceride (IMTG) content that is accessible for oxidation during exercise. Both adaptations are fundamental to training-induced improvements in insulin sensitivity. However, little is known about the mechanism that makes IMTG accessible for oxidation and whether a more time efficient approach of high intensity interval training (HIT) can induce similar adaptations to ET. Therefore, we aimed to investigate the effect of 6 weeks of either HIT or ET on IMTG metabolism, content of the lipid droplet protein perilipin 2 and insulin sensitivity in sedentary males. Sixteen participants (22 ± 1 years, BMI 23.7 ± 0.8 kg.m<sup>-2</sup>, VO<sub>2</sub>peak 3.03 ± 0.16 l.min<sup>-1</sup>) were randomly assigned to either HIT (performing 4-6 Wingate tests per session, 3 times per week) or ET (performing 40-60 min of moderate-intensity cycling, 5 times per week). Prior to and following training, aerobic capacity and insulin sensitivity (oral glucose tolerance test) were assessed. In addition, muscle biopsies were taken before and after 60 min steady state cycling exercise at ~65% pre-training VO<sub>2</sub>peak. Immunofluorescence microscopy was used to assess fibre type-specific training-induced changes in mitochondria, IMTG and perilipin 2. Training improved aerobic capacity (HIT 7 ± 2%, ET 15 ± 3%; main effect P < 0.01) and induced similar increases in mitochondrial density (HIT 39 ± 4%, ET 48 ± 14%; main effect P < 0.01). Training also increased resting IMTG content (HIT 1.7-fold, ET 2.4-fold; P < 0.05) and perilipin 2 content (HIT 2.1-fold, ET 3.4-fold; main effect P < 0.05). Before training, a decrease in IMTG content in type I fibres was observed in response to 60 min cycling with no difference between groups (HIT 17 ± 10%, ET 15 ± 12%; main effect P < 0.05). In comparison, training induced a significantly greater breakdown of IMTG in type I fibres during exercise (HIT 27 ± 13%, ET 43 ± 6%; P < 0.05), with no significant difference between groups. Insulin sensitivity, assessed using the Matsuda index, was also greater after training (HIT 56 ± 15%, ET 29 ± 12%, main effect P < 0.05). The results obtained suggest for the first time that the enhanced insulin sensitivity observed after both HIT and ET may be explained by similar increases in mitochondrial density coupled with greater IMTG metabolism. Increased perilipin 2 content also provides a potential mechanism through which IMTG becomes more accessible for oxidation. Thus, HIT is a time efficient intervention and induces similar metabolic and health adaptations as ET.

#### CODING OF BIOLOGICAL KINEMATICS DURING ACTION-OBSERVATION

ROBERTS, J.W., BENNETT, S.J., ELLIOTT, D., HAYES, S.J.

LIVERPOOL JOHN MOORES UNIVERSITY

**Introduction** Biological motion is suggested to be mapped onto a representation during action-observation. This process occurs within the 'mirror neuron circuit' and is known as the 'direct-matching hypothesis'. To date, it is unclear whether biological motion is processed by coding goal-directed information or the movement kinematics. To examine this question we instructed participants to learn a novel timing sequence by observing different types of visual stimuli (Exp. 1). **Experiment 1 Method** Forty-four participants were randomly allocated to four groups; natural biological motion (NT-BM); unnatural biological motion (UN-BM); non-biological motion (NBM); and control (CTL). To examine the contribution from biological motion, we created two models that displayed the same timing information but with different movement kinematics. The NT-BM model contained a typical peak velocity profile (i.e., early-to-mid trajectory) while the UN-BM model contained an atypical delay in time to peak velocity. The NBM group observed a computer-generated constant velocity model and the control group observed a blank screen. After action-observation all participants attempted to reproduce the timing sequence. **Results and Discussion** There was a significant decrease in relative timing error for all experimental groups ( $p < 0.05$ ). Moreover, for the kinematic data there was a significant difference between the UN-BM and all other groups. In support of the 'direct-matching' hypothesis, the UN-BM group significantly increased proportion of time-to-peak velocity and displacement at peak velocity to resemble the observed UN-BM model. These data indicate that biological kinematics are coded, possibly through the mirror circuit or a higher-order cognitive system. To examine the locus of this coding, we replicated Exp. 1 but added a secondary motor task designed to interfere with the motor system (i.e., lower-order system) during action-observation. **Experiment 2 Method** Forty-four new participants were randomly allocated to a NT-BM, UN-BM and CTL groups. During action-observation all participants observed the same models as presented in Exp. 1 but performed a secondary movement task that involved randomly moving a stylus through a spatial maze. **Results and Discussion** As per Exp. 1, all experimental groups learned relative timing ( $p < 0.05$ ). The kinematic data indicated that there was no difference between the groups in proportion of time-to-peak velocity and displacement at peak velocity. Therefore, and unlike Exp 1, when the motor system (lower-order system) is engaged in a secondary task the biological kinematics were not reproduced. These findings provide direct evidence that action-observation involves the coding of biological kinematics through the mirror circuit and primary motor cortex.

#### CONSCIOUS INFORMATION ABOUT THE TYPE OF FEEDBACK CAN CHANGE THE PROCESSING WITHIN THE PRIMARY MOTOR CORTEX DURING IDENTICAL TASK EXECUTION

LAUBER, B., KELLER, M., LEUKEL, C., GOLLHOFFER, A., TAUBE, W.

UNIVERSITY FREIBURG

**Introduction** The coding of force- and position-related information in the primary motor cortex is of fundamental importance when transforming planned movement intentions into action. One recent behavioral study proposed that position feedback is weighted heavier on soft objects (large deflections), while force feedback is weighted heavier on stiff objects (small deflections) (Mugge et al. 2009). However, a previous experiment of our group showed that force and position feedback of one and the same task resulted in differential motor cortical activity despite the same stiffness and compliance (Lauber et al. in revision). Therefore, we hypothesized that another factor may be important for the control of force- and position-related tasks: the conscious interpretation (or conscious sensory weighting) of the feedback itself. **Methods** To test whether the conscious interpretation of the feedback may be crucial in determining the motor cortical activity, we instructed subjects ( $n = 10$ ) to perform submaximal (20% MVC) muscular contractions of the first dorsal interosseus muscle (FDI). Subjects were told that they receive either position feedback about the position between thumb and index finger or feedback about the produced force by pressing a force transducer. However, in reality, subjects always received feedback about their force and never about their position. In order to highlight differences in motor cortical control, subthreshold TMS (subTMS) was applied during the tasks (position ("cheating task") and force task). **Results** SubTMS resulted in a suppression of the ongoing FDI EMG activity in both tasks. However, the mean suppression was significantly greater (force  $23.58 \pm 9.95\%$  versus position  $31.35 \pm 7.71\%$ ,  $P = 0.001$ ) and had a greater maximum amplitude during position control (force  $50.41 \pm 13.30\%$  versus position  $59.36 \pm 12.86\%$ ,  $P = 0.022$ ). The FDI background EMG obtained without stimulation showed no difference between the two tasks. **Discussion** The results of the present study reveal that neither the properties of the object (stiff versus soft/compliant) nor the feedback itself are crucial in modulating the neural activity. Differential conscious interpretation/sensory weighting of the feedback leads to changes in cortical processing. In this way, the current study further underlines that force and position control are differently coded within the primary motor cortex. **References:** Lauber B, Leukel C, Gollhofer A, Taube W. (2011). J Neurophysiol (in revision). Mugge W, Schuurmans J, Schouten AC, van der Helm FCT. (2009). J. Neurosci., 29, 5476–5482.

#### INVESTIGATING THE EFFECT OF A VARIABILITY CONSTRAINT ON RUNNING KINEMATICS AND EMG

HAUDUM, A., BIRKLBAUER, J., MÜLLER, E.

UNIVERSITY OF SALZBURG

**Introduction:** The complexity of sport behavior, especially the assembly of the different components and levels in order to achieve a coordinated behavior, has gained much attention. Since variability within and across levels affords the athlete's sensorimotor system the required adaptability and flexibility for a coordinated behavior under changing constraints, an elastic constraint was used to influence variability (e.g., in reactive phenomena) in a task specific manner to enforce permanent adaptation. The present study examined the effect of variable training with elastic constraints (i.e., tubes) on the variability of running kinematics and EMG. **Methods:** Whole body 3D-kinematics and lower extremity EMG (rectus femoris, tibialis anterior and lateral gastrocnemius) of ten male participants were recorded during pre- and post-tests. Both tests consisted of two treadmill-running intervals. One was performed with and one without the constraint with the order of situations being counterbalanced across runners. Participants performed 18 training sessions within 8 weeks. Kinematic and EMG variability within and between strides was analysed. Variance ratio (Hershler & Milner, 1978) of hip, knee and ankle angles, as well as of EMGs was calculated. **Results:** Repeated measures ANOVAs showed no significant differences between both situations for kinematic total stride data during pre- or post-test. With respect to EMG variability, however, an increase for all muscles was evidenced for the pre-test results ( $p < .01$ ,  $ES > .65$ ) in the constrained situation that was interestingly reversed after the intervention in the

more distal tibialis ( $p < .001$ ,  $ES = .67$ ) and gastrocnemius ( $p < .001$ ,  $ES = .75$ ) as variability was higher during normal running. Within stride analyses unveiled somewhat different results. Pre-test EMGs showed higher variability for tibialis ( $p < .05$ ,  $ES = .47$ ) and gastrocnemius ( $p < .01$ ,  $ES = .72$ ) during stance but only for tibialis ( $p < .05$ ,  $ES = .51$ ) during swing phase. For the post-test, no significant differences were found. The kinematic data at least demonstrated small effects on the more distal knee and ankle angles for swing phase ( $ES > .15$ ). Discussion: The different results obtained by using different levels of observation (kinematics vs. EMG) support the assumption that the variability on sublevels provides flexibility to adapt to a variable constraint primarily at the first exposure to new constraints. Moreover, it is likely that such intervention may still encourage an exploratory behavior that influences the interplay of the components involved due to an increased variability even in a routine behaviour like running. ### THE DELIBERATE PRACTICE CHARACTERISTICS OF SKILLED VERSUS LESS-SKILLED ATHLETES

COUGHLAN, E.K., FORD, P.R., MCROBERT, A.P., WILLIAMS, A.M.

LIVERPOOL JOHN MOORES UNIVERSITY

**Introduction** Deliberate practice is activity designed to improve current aspects of an individual's performance. It is characterized as being mentally and physically effortful, highly relevant to improving performance, and not immediately rewarding or inherently enjoyable (Ericsson et al., 1993). However, when athletes retrospectively recall their practice histories they rate these activities as enjoyable, rewarding, and as less relevant (e.g., Ward et al., 2007), which they might not have done during the activity itself or else the practice might not have been deliberate. When left to their own devices, skilled athletes may engage in deliberate practice activity that contains its predicted characteristics so as to improve their performance and rectify weaknesses. We test this hypothesis in a controlled environment using skilled and less-skilled Gaelic football players as they practice two different free-kick tasks. **Methods** Forty-five adult Gaelic football players were divided equally into three groups: skilled (SK), less-skilled (LSK) and control-skilled (CSK). Players completed pre-, post- and retention tests involving two free-kick shots at goal (out of hands, off ground). The SK and LSK groups practiced the two shots over four 30 min practice sessions between the pre- and post-tests, whereas CSK did not. Participants were free to self-select their activities during practice. The characteristics of deliberate practice were examined during practice using established measures of mental effort, physical effort, motivation and enjoyment. **Results** The SK group practiced the shot they were weakest on from the pre-test on 66% of the practice trials compared to 27% for the LSK group. SK rated their practice as 31% less enjoyable, 22% less motivating, 20% more physically exertive and 47% more mentally effortful compared to the LSK group. Although both groups improved their overall outcome scores for kicking from pre- to post-test, the SK group improved more on their weakest compared to strongest shot type, whereas the LSK improved more on their strongest compared to weakest shot. The CSK group showed no improvement on either shot type from pre- to post-tests. **Discussion** Findings support the prediction that experts when left to their own devices engage in deliberate practice activity (Ericsson et al., 1993), whereas less skilled individuals do not. Skilled Gaelic football players engaged in practice activities that contained the characteristics of deliberate practice, which may be a reason for their superior performance, whereas less-skilled players did not. **References** Ericsson, K. A. et al. (1993). *Psych Rev*, 100 (3), 363–406. Ward, P. et al. (2007). *High Ability Studies*, 18 (2), 119–153.

### CEREBRAL ASYMMETRY DURING EXERCISE USING NEAR INFRARED SPECTROSCOPY : AN EXAMINATION OF SELF-REPORTED TOLERANCE.

TEMPEST, G.1, EKKEKAKIS, P.2, BROOMFIELD, C.1, DREWELL, L.1, PARFITT, G.1

1 UNIVERSITY OF EXETER, UK; 2 IOWA STATE UNIVERSITY, USA

**Introduction** Grounded in the Dual-Mode Theory (Ekkekakis 2003) self-reported tolerance of exercise intensity is a dispositional trait, with a biological basis, which may account for inter-individual variability in affective responses to exercise (Ekkekakis et al. 2005). Research has implicated frontal cortex (FC) asymmetry in the awareness of the physiological condition (Craig 2009, 2003) and should reflect self-reported tolerance. The objective of this study is to examine the activity of the FC during exercise to investigate asymmetry and the impact of the dispositional trait of self-reported tolerance using NIRS. **Methods** Based on tolerance scores assessed by the Preference for and Tolerance of the Intensity of Exercise Questionnaire (PRETIE-Q; Ekkekakis et al. 2005) subjects were selected to a High Tolerance (High;  $n=7$ ) or Low Tolerance (Low;  $n=7$ ) condition. Subjects completed a cycling ramp protocol to volitional exhaustion and exercise intensity was standardized against metabolic processes as recommended by Ekkekakis et al. (2009) and Rooks et al. (2010). Changes in Deoxyhaemoglobin (HHb), Oxyhaemoglobin (O2Hb), Total Haemoglobin (tHb) and Tissue Oxygenation Index (TOI) were measured from the left and right FC using 2-channel NIRS. The average change from ventilatory threshold (VT) to respiratory compensation point (RCP) and RCP to exhaustion (end) were recorded. **Results** A significant condition (High, Low) by time (VT to RCP, RCP to end) interaction ( $p < .05$ ) on changes in TOI was recorded. This was due to an increase in TOI in the High condition from VT to RCP but a decrease in the Low condition. Both conditions decreased in TOI from RCP to end. A significant condition by FC (Left, Right) by time interaction ( $p < .05$ ) on HHb was also recorded. A crossover interaction with a disproportional split in HHb between the Left ( $3.96 \pm .77$ ) and Right ( $1.45 \pm .44$ ) FC in the High condition at VT to RCP that reversed at RCP to end (Left =  $1.03 \pm .63$ , Right =  $3.89 \pm .79$ ) explained the effect. There were no differences in the Low condition. No other significant effects were recorded. **Discussion** These findings indicate differential patterns of activation of the FC dependent on self-reported tolerance and asymmetry of the FC at exercise intensities above VT. The results support the dual-mode theory and provide insight into underlying mechanisms of exercise-induced responses. On-going research is exploring the potential effect of intervention strategies on FC activity. **References** Craig (2008) *Curr Opin Neurobiol* 13:500-505 Craig (2009) *Nat Rev Neurosci* 10:59-68 Ekkekakis (2003) *Cognition Emotion* 17:213-239 Ekkekakis et al (2005) *J Sport Exerc Psychol* 27:350-74 Ekkekakis (2009) *J Sport Exerc Psychol* 31:505-53 Rooks et al (2010) *Prog Neurobiol* 92:134-150

### EARLY NEURAL RESPONSES TO STRENGTH TRAINING

CARROLL, T.J., SELVANAYAGAM, V.S., RIEK, S.P.

THE UNIVERSITY OF QUEENSLAND

**EARLY NEURAL RESPONSES TO STRENGTH TRAINING** Carroll, TJ (1), Selvanayagam, VS (1,2), Riek, SP (1) (1) School of Human Movement Studies, The University of Queensland, Brisbane, Queensland, AUSTRALIA, 4072; (2) Sports Centre, University of Malaya, 50603, Kuala Lumpur, MALAYSIA **Introduction** The neural adaptations that accompany strength training have yet to be fully determined. Here we addressed this topic by testing the idea that strength training might share similar mechanisms with some forms of motor learning. Since ballistic motor learning is accompanied by a shift in the resultant direction of muscle twitches induced by transcranial magnetic stimulation (TMS) towards the training direction (Classen et al. 1998), we investigated whether single isometric strength training sessions can induce similar

TMS-evoked twitch effects. Methods Twitch force resultant vectors and motor evoked potentials (MEPs) induced by TMS were measured before and after single sessions of strength training involving the forearm muscles. The training protocols involved either brief (less than 1s) or sustained (2s) maximal isometric contractions with an initial ballistic component, or sustained contractions (2s) with a slow, ramp onset (over 2s). Participants (n=12) each performed three training protocols (consisting of 4 sets of 10 repetitions) and served as their own control in a counter balanced order. Results All three training protocols caused a significant immediate shift in TMS-induced twitch force resultant vectors towards the training direction (30-40% of the angular difference between initial direction and training direction,  $p < 0.05$ ), followed by a gradual shift back towards the pre-training direction. The strongest effect was found when training involved both ballistic and sustained force components. There were no large or consistent changes in the direction of twitches evoked by motor nerve stimulation for any of the three training protocols. Discussion We showed that a single session of strength training shifts TMS-induced twitch force direction towards the training direction in a similar way to ballistic motor learning. The changes were at least partly due to neural adaptation as muscle responses to motor nerve stimulation were unaffected. Furthermore, the data show that while "typical" strength training involving sustained maximal force production is sufficient to induce change, the strongest early neural effects are found when both ballistic and maximum sustained force are produced. We suggest that these early neural responses to training reflect an important component of neural adaptation that summates over multiple sessions to ultimately enhance strength. ### IS-PM14 Exercise Prescription in Transplant Patients

#### **PATHOPHYSIOLOGY OF EXERCISE INTOLERANCE IN HEART TRANSPLANT RECIPIENTS: ROLE OF HIGH-INTENSITY TRAINING**

HAYKOWSKY, M.

UNIVERSITY OF ALBERTA

The purpose of this presentation is to discuss the underlying mechanisms for exercise intolerance in heart transplant recipients and the role of high-intensity interval training to improve cardiovascular function and fitness.

#### **ROLE OF CARDIOPULMONARY EXERCISE TESTING IN HEART FAILURE PATIENTS BEING ASSESSED FOR CARDIAC TRANSPLANT**

SCHULTE, F.

HEART CENTRE, CHEMNITZ

Cardiopulmonary exercise testing (CPET) is a simple, reproducible and objective test for diagnosing patients with exercise intolerance. The talk describes the importance of CPET besides other diagnostic tools for assessing patients with severe heart failure and its main criteria for optimal timing of Heart transplantation. It reviews the physiological principles of exercise intolerance in cardiac patients and discusses the main CPET-criteria for risk stratification: Peak oxygen consumption, ventilatory equivalent and anaerobic threshold.

#### **EXERCISE REHABILITATION FOR PATIENTS WITH VENTRICULAR ASSIST DEVICES.**

BINDOFF, C.

ROYAL BROMPTON AND HAREFIELD NHS FOUNDATION TRUST

Once a ventricular assist device (VAD) has been implanted, specific rehabilitation exercise is crucial to prepare the patient either for cardiac transplantation, for upgrade to long-term VAD or for VAD removal following myocardial recovery. There are some specific considerations for rehabilitation of these patients which should be addressed in order to provide a safe and effective exercise programme. The considerations for exercise in both short-term and long-term VADs will be highlighted. Currently there is a lack of evidence regarding exercise training protocols for people who have either short-term or long-term VADs implanted for heart failure. The papers which have described rehabilitation regimens document cases following long-term left ventricular assist device (LVAD) insertion. Of these, some are single case studies, some have fewer than 10 subjects others are retrospective analyses. Patients with long-term VADs are being rehabilitated sufficiently well to enable discharge home or into the community setting at the majority of centres implanting VADs. The instigation of a progressive mobility programme for patients with short-term VADs is however innovative, and has gone beyond the manufacturers' original conception for these devices. The use of both short-term extracorporeal and long-term VADs has brought about new challenges for exercise prescription. Short-term VADs are being inserted more frequently and in a wide variety of clinical situations (post-cardiotomy for cardiogenic shock, post cardiac transplantation and for right ventricle support post LVAD insertion). Usually these patients are confined to bed in the intensive care unit until the device is either explanted or up-graded. There are many different versions of long-term VADs available (pulsatile and non-pulsatile devices) and the functional exercise capacity of the patient will be dependent upon the ability of the device to deliver an output which matches the intensity of exercise required. Specific exercise prescription is essential for patients requiring a VAD to combat physical deconditioning that occurs with heart failure and with prolonged periods in bed on the intensive care unit (ICU) after device insertion. Separate considerations are implicated for assisting patients with short-term and long-term VADs to exercise. The physical and psychological components of health are both much improved by early rehabilitation within the ICU setting, and establishing a positive exercise principle is vital for the long-term outcomes for a patient with an implanted VAD. We are at the beginning of a new area of scientific study with this fascinating population of pulse-less patients. New exercise protocols need to be evaluated to assess the effects on myocardial recovery and improvements in functional capacity to fully understand the potential of these evolving devices.

### IS-SH02 Morals and Ethics in Applied Sports Psychology

#### ETHICAL PRINCIPLES FOR APPLIED SPORT PSYCHOLOGISTS OF THE EUROPEAN SPORT PSYCHOLOGY FEDERATION

JOHNSON, U.

*HALMSTAD UNIVERSITY*

Introduction The term sport psychology refers to psychological aspects of sport, physical recreation, physical education, exercise, health, and related physical activities. The European Sport Psychology Federation (FEPSAC) works for the development of the field of sport psychology and exercise from a European and global perspective. Due to Sport Psychology professionals' specialised knowledge and the hypothetical potential for harm, the ethical principles are guidelines for FEPSAC professionals to act responsibly and ethically in the provision of professional services. These principles are intended to ensure the dignity and welfare of all groups, organisations and individuals with whom FEPSAC professionals may interact with and provide professional services to. Altogether seven ethical principles is stated that guides FEPSAC research and applied sport psychology. These are: a) Professional and Social Responsibility, b) Competence, c) Consent, d) Confidentiality, e) Integrity, f) Personal Conduct, g) Research. Recommendations a) FEPSAC members are responsible for safeguarding the public and the FEPSAC from members who are deficient in ethical conduct. They should uphold professional and social standards of conduct and accept appropriate responsibility for their behaviour. b) FEPSAC members should strive to maintain the highest standards of competence in their work. c) No FEPSAC members should undertake any work without first having the informed consent of all participating clients. This is done primarily, through the client signing a document setting detailing all information relevant to the proposed investigation, intervention, treatments or test. d) FEPSAC members should preserve the confidentiality of the information acquired in their work which should not be developed without prior written consent of a client. Clients should be informed that they have a right to a copy of such information relating to them if so requested. f) FEPSAC members should promote integrity in research, teaching, and practice of sport psychology. g) FEPSAC members shall conduct themselves in a manner beneficial to the well-being of their clients and in a way that brings credit to the field of sport psychology. h) FEPSAC members should comply with codes, statements, guidelines and other directives developed. Moreover, they should accurately report the data they have gathered and the results of their research, and state clearly if any data on which the publication is based have been published previously. Reference FEPSAC Position Statement 9. Ethical principles of European Sport Psychology Federation, 2011.

#### THE POTENTIAL VIOLATION OF SEXUAL BOUNDARIES IN SPORT PSYCHOLOGY CONSULTANCY: IMPLICATIONS FOR RESEARCH AND PRACTICE

HARWOOD, C.G., LITTLE, G.

*LOUGHBOROUGH UNIVERSITY*

The purpose of this presentation is to examine issues surrounding the potential violation of sexual boundaries in sport psychology consultancy and critically evaluate the current state of knowledge in the field. Limited discussion and research relating to this ethical issue exists within sport psychology; the discussion that has occurred has mainly focused on erotic transference and countertransference (Andersen, 2005). Research and knowledge from clinical psychology, counseling psychology and psychotherapy proffers ideas for discussion and research into the factors that precipitate sexual boundary violations. The relevance of the controversial practice of touch as a therapeutic tool and a stimulus for sexual boundary violations is considered, alongside implications for the training of neophyte practitioners through role playing, peer support and supervision.

#### ETHICAL CHALLENGES FACED BY SPORT PSYCHOLOGISTS WORKING WITH TALENTED AND OLYMPIC ATHLETES AND THEIR COACHES

WYLLEMAN, P.

*VRIJE UNIVERSITEIT BRUSSEL*

With the growing importance of the role of the sport psychology consultants (SPC) in elite sport, so has the need for clear boundaries of the role of the SPC and their adherence to ethical principles become much more poignant. More specifically, the SPC is required, amongst others, to have an expanded knowledge of ethical/legal guidelines based on real experiences with clients, awareness of the legal and ethical considerations and the ability of handling special situations (e.g., abuse), appreciation of the impact of one's internal states on assessment of clinical outcomes (Kenkel & Peterson, 2010). In this presentation, three case studies will be presented and used to reflect with the ethical guidelines regarding intervention by an SPC in general, and with the ethical guidelines formulated by the European Federation of Sport Psychology (FEPSAC) in particular. In conclusion, some recommendations will be formulated with regard to ethical guidelines for SPC.

## Invited symposia

### IS-PM05 DEBATE: To Screen or Not To Screen That is the Question: Europe Vs. USA (Sponsored by Philips)

#### PRE-PARTICIPATION SCREENING, IS IT WORTH IT?: EUROPE VS. NORTH AMERICA

WHYTE, G.

*LIVERPOOL JOHN MOORES UNIVERSITY*

Conversely, the European Society of Cardiology has denounced the use of questionnaires in isolation and has forcefully recommended the inclusion of a resting 12-lead electrocardiogram (ECG) as part of the screening process. These divergent opinions have generated an intense, emotive, and at times acrimonious debate among medical professionals and the lay public. Whilst the issues of sensitivity and

specificity are central to the continental divide it is cost-effectiveness that is at the heart of the pre-participation screening debate. Unfortunately, there are no direct comparisons of screening strategies with vs. without an ECG component. This lack of data is not a minor issue since estimates of the cost of implementing an ECG based screening program in the United States alone have been as high as \$2 billion. Beyond the Dollar vs. Euro debate lies perhaps the most important issue: efficacy. Do pre-participation cardiovascular screening programmes save lives? How do we deal with an athlete with known disease? What do we do with 'grey zone' athletes? What are the risks of training and competition in the presence of disease? Are we in a position to disqualify athletes from competing? These questions and more remain an area of divergent opinion with limited empirical support on either side. Given the extraordinary economic and personal cost of pre-participation cardiovascular screening programmes as well as the tragic loss of a young athlete, it is essential that high quality objective evidence rather than emotion guide policy. Pre-Participation Screening, is it Worth it?: Europe vs. North America will bring together two leading figures from across the continental divide to provide a frank and open debate on the differences that exist between the opposing communities. Following a 20 minute presentation from Professor's Whyte and Levine each presenter will be deliver a 5 minute rebuttal followed by open questions from the audience. The session will close with a vote from the floor: 'Is Pre-Participation Cardiovascular Screening Worth It?'.

#### **PRE-PARTICIPATION SCREENING, IS IT WORTH IT?: EUROPE VS. NORTH AMERICA**

LEVINE, B.

*UNIVERSITY OF TEXAS SOUTHWESTERN MEDICAL CENTER AT DALLAS*

The sudden death of a competitive athlete stirs great emotion among family, fans, and the media. Because such athletes are generally young, vigorous and apparently healthy with many years of productive life lost, these unfortunate events have generated powerful interest among the public and the medical profession regarding what could have been done to prevent such catastrophes from occurring. Despite the desire for a solution, the global debate has often stalled because of a continuing disagreement on the incidence and etiology of SCD in young athletes. This disagreement has been fuelled by a continental divide perpetuated by the polarized views emanating from North America and Europe. Whilst incidence and etiology have acted as the building block of this continental divide, it is the debate surrounding pre-participation cardiovascular screening that is perhaps the most hotly debated topic in sports medicine. The debate centres on the best paradigm to screen apparently healthy, asymptomatic young athletes. On one side of the issue, experts from the American Heart Association first in 1996 and again in 2007 recommended that a 12-point evaluation focusing on the presence of symptoms during exercise and a family history of sudden cardiac death is the most appropriate strategy.

##### **THE ROLE OF CARDIAC STEM CELLS IN CARDIAC ADAPTATIONS TO PHYSIOLOGICAL AND PATHOLOGICAL STRESS**

ELLISON, G.

*LIVERPOOL JOHN MOORES UNIVERSITY*

In long lived organisms most somatic cells have a lifespan significantly shorter than the organism. Most, if not all, mammalian adult tissues harbour a small subpopulation of tissue-specific stem-progenitor cells that differentiate into some -or all- the parenchymal cells of their tissue of origin. Thus, adult stem-progenitor cells likely have been evolutionarily selected to maintain cellular tissue homeostasis and to repair physiological wear-and-tear throughout life, acting as a cell reservoir to replenish cycling-incompetent parenchymal cells. Cardiac resident stem-progenitor cells in the embryonic, neonatal and adult mammalian heart, including human, have been identified by different membrane markers (c-kit, Sca-1, Abcg-2, Flk-1) and transcription factors (Isl-1, Nkx2.5, GATA4). The adult c-kit positive (c-kitpos) cardiac stem cells (CSCs) are clonogenic, self-renewing and multi-potent, in that they differentiate into the 3 cardiac lineages; cardiomyocytes, smooth muscle and endothelial cells (Beltrami et al. 2003, Cell, 114, 673). They participate in adaptations to myocardial stress and have a strong regenerative capacity restoring most cardiomyocytes and small vessels lost in an infarct. These findings have not only challenged the established notion of the heart as a terminally differentiated organ but have placed it squarely amongst other organs with regenerative potential such as the liver, skin, muscle, CNS; despite the fact that the working myocardium is mainly composed of terminally differentiated contractile cells. c-kitposCSCs are activated in response to pathological or physiological stimuli, whereby they enter the cell cycle and differentiate into new myocytes (and vessels) that significantly contribute to remodelling of functional myocardium. Here, we will present data that shows exercise training results in myocardial mass remodelling through both myocyte hypertrophy as well as hyperplasia. The latter is due to the activation and ensuing differentiation of c-kitposCSCs into newly-formed myocytes and capillaries. We also show that c-kitposCSCs are indispensable but efficient to repair extensive cardiac diffuse damage, leading to complete cellular, anatomical and functional recovery. Growth factors up-regulated with physiological and pathological stress determine c-kitposCSC activation, proliferation and differentiation. The future of cardiovascular regenerative medicine is dependent on our success in dissecting the biology and mechanisms regulating CSC fate. This information will provide the tools for the design of more physiologically relevant clinical regeneration protocols. This work is supported by the BHF, FP7 EU Marie Curie (224853), CARE-MI (242038) and Endostem (241440).

##### **AEROBIC INTERVAL TRAINING: THE BEST MEDICINE FOR PATIENTS WITH CARDIOVASCULAR DISEASE**

WISLØFF, U.

*NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY*

Prospective, observational studies suggest that low aerobic fitness, measured as maximal oxygen uptake, is a strong and independent predictor for total and cardiovascular mortality in healthy individuals and in patients with cardiovascular disease. Epidemiological, clinical and experimental data support an important role for physical activity and systematic exercise training in prevention, treatment and reha-

bilitation of several life-style related conditions, such as overweight and obesity, diabetes, and cardiovascular disease. Clearly, it would be advantageous to identify the optimal exercise regimes for selected patient groups to maximize the benefit. However, no clear agreement of what constitutes the most optimal training programs with regard to intensity, frequency and duration has yet been identified, although substantial research programs have been set up to study this. The presentation will give examples of the effects of training programs that utilize a relatively high intensity of the exercise, from an epidemiological point through experimental and clinical studies. A hypothesis is that on a small and a large scale, the more beneficial effect of high intensity exercise training also translates to greater improvements in exercise capacity, quality of life, and reduced morbidity and mortality.

#### PP-BN01 Sports Biomechanics 1

##### EXAMINATION FOR CALCULATING BODY SEGMENT MASS DISTRIBUTIONS BY MEANS OF LASER 3D BODY SCANNING METHODS IN JUNIOR MALE GYMNASTS

HAKAMADA, N.1, FUNATO, K.2

1:SPORTS TRAINING CENTER, NIPPON SPORT SCIENCE UNIVERSITY (TOKYO, JAPAN), 2 :LABORATORY FOR HUMAN MOVEMENT SCIENCES, NIPPON SPORT SCIENCE UNIVERSITY (TOKYO, JAPAN)

**Introduction** In Gymnasts, body segment parameters such as location of whole body/segment mass center, segment mass and its distribution are important factors for both biomechanical research and performance assessment. Therefore, purpose of this study were to investigate validity of a whole body volume and segmental volumes using three dimensional anthropometry methods, and to estimate segment mass distribution in order to demonstrate anthropometric characteristics of elite junior male gymnast. **Methods** 7 male junior gymnasts (GM: Age=13.9±0.7yrs, BH=143.3±9.0cm, BW=39.9±5.8kg) and 7 junior high school students (NM : Age=13.7±0.7yrs, BH=157.7±10.4cm, BW=44.9±8.0kg) participated in this study. Whole body volume and each segmental volume were measured by using three dimensional whole body scanner (BLS: Hamamatsu Photonics KK). Body composition including whole body volume and lung volume were measured by using air displacement plethysmography (BODPOD:LMI ). Whole body scanning data was divided into 14 segments (SM: Head, Trunk, Upper arm, Forearm, Hand, Thigh, Shank, Foot ) in the same manner as the previous study done by C.E.Clauser,1969 according to anatomical landmark points. Trunk volume was corrected by subtracting lung volume. Each segment mass was determined by multiplying each segment volume and respective segment density reported by C.E.Clauser. Relative segment masses to whole body mass (%SM) were also calculated. **Results** Mean value of the difference(%) in whole body volume measured between ADP and BLS was 3.1%. Difference between directly measured body weight and sum of each segment mass was within 3%. There were no significant differences in segment masses between GM and NM. However, %SM for upper arm and fore-arm in GM were significantly larger than those in NM (upper arm; GM=2.82±0.15%, NM=2.56±0.12%, forearm; GM=2.07±0.08%, NM=1.81±0.08%, $p<0.001$ ). Trunk volume was almost same between GM and NM, however upper trunk volume relative to trunk volume in GM was significantly larger than those in NM. **Discussion** Present results indicate that estimation of body segment mass by using 3D laser scanning anthropometry might be valid and applicable for demonstrating segment characteristics among different athletes. With comparison to normal person, elite male junior gymnasts were anthropometrically characterized as relatively larger segment masses in upper trunk and upper limbs, indicating trainability and superiority to gymnastics movements. **References** Clauser C.E. (1969). AMRL Technical Report TR,69-70.

##### KINEMATICS OF BOOT-GROUND INTERACTION DURING SOCCER TURNING ON OUTDOOR NATURAL TURF

UNDERDOWN, T.

LIVERPOOL JOHN MOORES UNIVERSITY

**Rationale** Acquiring enough traction from boot-surface interface in soccer is a key component of the game (Grund & Senner, 2010). Inadequate grip may decrease performance and increase injury risk (Livesay et al., 2006). Player-surface interaction during tasks such as cutting and turning has not been well documented. The focus of the present study was to examine initial foot landing velocities, phase durations of ground-contact (GC) and typical slip magnitudes based on high-speed kinematics of foot-ground interaction on outdoor soccer pitches. **Method** Kinematics of 19 semi professional players aged 22±1.3 years were captured at 500Hz while performing a 135 degree V-cut with their dominant leg, using 6 infra-red cameras (Qualisys, Sweden). All players executed 5 turns on 6 different elite natural turf surfaces. A three-segment foot model (rear-foot, mid-foot & forefoot) was used to monitor 3 phases of GC (Phase 1 HS-FF, Phase 2 FF-HR & Phase 3 HR-TO, (HS=heel strike, FF=flat foot, HR=heel rise & TO=toe off). HS was determined using the vertical foot velocity (Zeni et al., 2008) and verified with force platform measures in a laboratory. Kinematic data were low-pass filtered using a 25Hz cut-off frequency except phase 1, with high frequency motion filtered using a 75Hz cut-off. **Results** Overall mean landing velocity for all pitches was 2.60±0.24m/s; the mean total turn time was 0.491s. All players landed heel first with 18 players spending 0.026±0.022s during phase 1, with one player taking 4 times as long to complete that phase (0.067±0.07s). Phase 2 took 0.324±0.084s, with individuals maintaining consistent times across pitches. Phase 3 had the majority of players spending 0.121±0.067s, although for one pitch 7 players took 0.29±0.093m/s. During phase1 the rear-foot had a consistent resultant horizontal slip of 1.7±0.3cm (1.3-2cm range). Phase2 experienced the greatest slip of 1.9±0.3cm (1.6-2.5cm range), while in Phase 3 there was minimal slip for all pitches with a range of 0.05-2mm. **Discussion** Stiles et al. (2011) found similar landing velocities (2.51-2.64m/s) for a 180 degree turn on indoor natural turf. This can be used to provide a better replication of initial impact conditions for measuring turf traction using mechanical rigs. Timings of GC phases have implications for footwear grip design and stud placement. The current group of players wore hard ground molded-stud boots: soft ground/longer stud configurations may modify GC phases. The majority of players in phase 1 have similar heel-first strategy occurring rapidly but some players spend longer in phase 2 compared to the mean. This appears to be related to greater knee flexion and shank lean into the turn but analysis of traction related movement strategies is beyond the scope of this paper. **References** Livesay, G, Reda, D, Nauman, E. ## COULD A BASKETBALL TEST BATTERY BE AN APPROPRIATE MODALITY TO CLASSIFY THE PLAYERS WITH INTELLECTUAL DISABILITY IN PROMOTION CATEGORY?

FRANCIOSI, E., EMERENZIANI, G.P., PES, G., GUIDETTI, L., BALDARI, C., GALLOTTA, M.C.

UNIVERSITÀ DEGLI STUDI DI ROMA

**Introduction** The aims of this study were to verify whether the basketball test battery previously proposed for the Competitive category (Comp) could be an appropriate modality to classify the players with intellectual disability (ID) in Promotion category (Pro); to assess basketball abilities before (PRE) and after (POST) a 8-months training in players with ID in relation to Comp and Pro categories; and finally to analyse the variation of specific basketball abilities by subjects' ID levels. **Methods** Forty-one adult basketball male players with ID (15% Mild, 54% Moderate, 29% Severe, and 2% Profound ID) were divided in 17 and 24 subjects playing into Comp and Pro category, respectively. PRE and POST a 8-month specific training, all players were assessed through the basketball test battery for assessing individual global, ability level and fundamental area scores. **Results** The individual global, ability levels II and III, and all fundamental areas scores significantly affected by the Category and Intervention ( $p < 0.05$ ). The level I was significantly changed after the intervention period regardless the Category ( $p < 0.01$ ), while the shooting was affected by the interaction between Category and Intervention ( $p < 0.01$ ). The Fisher's post-hoc results showed significant differences between the categories (Comp vs Pro) in score of individual global ( $p < 0.0001$ ), level I ( $p < 0.01$ ), level II ( $p < 0.01$ ), level III ( $p < 0.05$ ), and in all fundamental areas ( $p < 0.01$ ). Particularly, the individual global score in both categories significantly increased ( $p < 0.01$ ). Principally, the players of Comp significantly improved in level III ( $p < 0.05$ ), in ball handling ( $p < 0.05$ ), reception ( $p < 0.01$ ), passing ( $p < 0.01$ ), and shooting ( $p < 0.01$ ) scores. Instead the players of Pro improved significantly in level II ( $p < 0.01$ ), in ball handling ( $p < 0.05$ ), reception ( $p < 0.05$ ), and passing ( $p < 0.01$ ) scores. Individual global, ability level I, II and III, and fundamental area scores were negatively correlated to ID level indicating that players with lower ID obtained higher ability scores. **Discussion** Both players with ID of Pro and Comp improved significantly after a 8-month basketball training in level II and III, respectively. After the intervention period, the players of Comp improved their functional abilities (total score) and achieved higher ability levels, while the players of Pro had difficulties in increasing the starting level of their specific skills in a short time, despite showing some degree of score improvement within a specific ability level.

## UNDERWATER ARM STROKE MOTION ANALYSIS: COMPARISON OF THEORETICAL MODEL AND EXPERIMENTAL DATA

SILVATTI, A.P., TELLES, T., CERVERI, P., BARROS, R.M.L.

UNIVERSITY OF CAMPINAS, POLITECNICO DI MILANO

**UNDERWATER ARM STROKE MOTION ANALYSIS: COMPARISON OF THEORETICAL MODEL AND EXPERIMENTAL DATA** Amanda P. Silvatti 1,2, Thiago Telles 1, Pietro Cerveri 2 and Ricardo M. L. Barros 1. 1 - Faculty of Physical Education, University of Campinas, Brazil 2 - Biomedical Engineering Department, Politecnico di Milano, Italy **Introduction** Swimming has been taught and trained based on some very spread theoretical model such as the described in Maglischo (1993). However, accurate experimental data of swimmers motion can now be obtained using a 3D underwater kinematical analysis system (Silvatti, et al. 2010). Such methods can provide individual and detailed evaluation of the swimmers performance. Thus, this work intends to analyze and compare the hand underwater motion kinematics in the four swimming styles with the model described in Maglischo (1993). **Methods** The DVideo kinematical analysis system (Figueroa et al., 2003; Silvatti et al. 2010) was used for underwater online data acquisition and processing. The system consisted of two gen-locked Basler cameras with wide angle lens (100Hz) enclosed in housings. The volunteers were four highly trained male competitive swimmers and they performed four tasks, one in each swimming style. The 3D hand extremity position in the underwater phase of the both arms was obtained by manual digitizing. The raw position time data was smoothed using a low pass digital Butterworth filter (cutoff 5 Hz). The following variables were calculated for each swimmer and each arm: a) hand trajectory (frontal, lateral e inferior view); b) arm stroke width (ASW); c) arm stroke length (ASL); d) arm stroke depth (ASD); e) maximum velocity (MV) and f) maximum acceleration (MA). All variables were compared among swimmers, right and left hands, swimming styles and with the models described in Maglischo (1993). **Results and Discussion** The right hand of the volunteer 2 in the breaststroke showed the longest ASL (1.42m). the greatest values of the MV was found in the butterfly (58.38m/s<sup>2</sup>), that was detected in volunteer 4 left hand. The MA greatest value was detected in the same hand and volunteer, but in backstroke (4.69m/s). The mean values of ASW, ASD and MV for both hands in all styles were in agreement with the values expected (Maglischo, 1993). The graphic plots with the hand trajectory provided the identification of the movement pattern. To improve the arm stroke analysis the air phase should be included. **Conclusion** The underwater analysis system was able to quantify the hand's trajectory and the linear kinematics variables in all swimming tasks, identifying the similarities and differences between the results and the theoretical model. **References** Figueroa, et al. ## EFFECTS OF CHANGES IN ANGULAR MOMENTUM ON PERFORMANCE DURING DISCUS THROWING

YAMAMOTO, D., URATA, T., TANABE, S., ISHIKAWA, M., ITO, A.

OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCE

**Introduction** Few studies about angular momentum during discus throwing have been reported (Dapena, 1993; Miyanishi, 2000). However, it is not clear whether throwing distance is related to changes in the angular momentum and throwing distance. It is necessary for providing useful information for training and instruction to clarify these relationships. In the present study, relationships between throwing distance and angular momentum in each body segment about the vertical axis (H-z) were investigated in discus throwers with extensive records. **Methods** Subjects were 19 male discus throwers (records, 38.67-68.94 m) from collegiate athletes to world level athletes. Throwing movements when each subject threw the longest distance were recorded by two video cameras (60 Hz) and digitized. The three-dimensional coordinates of the body and the discus were calculated using the direct linear transformation method. The throwing movement was divided into 5 phases, the H-z of whole body, the discus and the selected five segments of torso and head (trunk), right arm, left arm, right leg and left leg were calculated. **Results** Increment of the H-z of whole body during first double leg support phase (DS) just behind turn start and decrement of the H-z of whole body during delivery phase (DV) just before release had significant positive correlations ( $r=0.856$  and  $r=0.546$ , respectively). Significant positive correlations were found between throwing distance and increment of trunk, right arm, left arm, right leg, left leg and discus during the DS ( $r=0.523$ ,  $r=0.585$ ,  $r=0.828$ ,  $r=0.793$ ,  $r=0.509$  and  $r=0.510$ , respectively). During the DV, increment of the H-z of discus and right arm had significant positive correlations with throwing distance ( $r=0.820$  and  $r=0.735$ , respectively). In contrast, decrement of the H-z of left arm and left leg had significant positive correlations with throwing distance

( $r=0.632$  and  $r=0.510$ , respectively) Discussion Our results suggest that storing of the larger H-z into whole body using both legs during the DS is necessary for achieving higher performance. The results of changes in H-z during the DV suggest that the H-z of whole body was transferred into the discus. And when focusing on the H-z of each segment, the H-z of left arm and left leg were more transferred to the discus through the right arm in the throwers with longer distance. References Dapena, J. (1993) Track Technique, 125, 3977-3983. Miyanishi, T. (2000) Research Quarterly For Athletics, 43 (4), 29-36.

### **EFFECT OF MENTAL FATIGUE AND TOTAL SLEEP DEPRIVATION ON CYCLING BIOMECHANICAL PARAMETERS DURING A WINGATE TEST**

LERICOLLAIS, R., GAUTHIER, A., BESSOT, N., ZOUABI, A., DAVENNE, D.

UNIVERSITY OF CAEN BASSE-NORMANDIE

Introduction The movement involved during the Wingate test is recognized to be complex and requiring the use of several muscle groups based on a free pedal rate. Thus, the performance and fatigue observed during this cycling exercise are the results of a complex organization of movements. This organization might be driven by the central nervous system, in particular the brain (Raasch and Zajac, 1999). We can hypothesize that a specific perturbation of the sensorimotor mechanisms in the brain could disturb the organization of cycling movement during an anaerobic exercise. Therefore, the aim of this study was to evaluate the effects of a nocturnal mental fatigue on muscle fatigue and biomechanical cycling parameters recorded in the morning of the following day during a Wingate test. Methods Twenty active male subjects performed a 60-s Wingate test at 06h00 during 2 test sessions the day after a normal night and a total sleep deprivation night combined with a mental fatigue consisting of an 8-h simulated driving task. During each test session, the Peak Power (PP) and the Mean Power over 60 s (MP60s) were analyzed. The decrease in power output throughout the Wingate test was used to evaluate the subjects' fatigue. Kinetic (angle of peak torque and range in torque variation) and kinematic (mean angle and range of motion (ROM) of the hip, knee and ankle) variables were studied during 2 intervals of the Wingate test: I1 from the 5 to the 20th s and I2 from the 45 to the 60th s. Results The results showed that performances (PP and MP60s), fatigue, kinetic and kinematic patterns were unaltered after a total sleep deprivation night during which a prolonged sustained attention task was done in order to specifically impair the vigilance of the subjects. Discussion The stability of performances, fatigue and biomechanical patterns of movement recorded during the anaerobic cycling exercise after a perturbation in the neural system does not seem to confirm our previous assumption. It can be hypothesized that there are cerebral compensatory responses (Drummond et al., 2004) which could allow athletes to preserve the cycling patterns in order to maintain a coherent movement, and thus maintain the performance level. We can also suppose that the organisation of cycling movement could be controlled at a lower level than the brain, such as the spinal level. Thus, the motor control which is responsible for pedalling could be initialized at a supra-spinal level, but the mechanisms of movement control during the pedalling task would be regulated at a spinal level (Raasch and Zajac, 1999). ### **JOINT-SPECIFIC POWER OUTPUT OF ELITE TRACK SPRINT CYCLISTS**

BARRATT, P.R., GARDNER, A.S., KORFF, T.

BRUNEL UNIVERSITY

Maximal crank power is a key determinant of performance in track sprint cycling. Those athletes who are able to produce greater crank power are likely to be more successful in a sprint race. The overall purpose of this study was to understand the mechanisms underlying differences in maximal crank power production between elite and non-elite cyclists. Power delivered to the crank during cycling is generated by the muscles that span the ankle, knee and hip joints. Understanding differences in relative joint power contributions to crank power between elite and non-elite cyclists could give us hints about the factors that determine world class performance, which in turn would have implications for coaching practice. Therefore, the specific aim of this study was to quantify differences in the relative contributions of the muscles spanning the hip, knee and ankle joints between elite and non-elite cyclists. Eight elite track sprint cyclists and eight trained but sub-elite track cyclists performed seated iso-kinetic maximal cycling at 120 rpm. Two-dimensional crank forces and limb kinematics were collected over three crank revolutions. Joint-specific powers of the lower limb were calculated via inverse dynamics, averaged over extension and flexion phases, as defined by joint angular velocity, and normalized to overall crank power. Elite compared to sub-elite track sprint cyclists generated less relative hip extension power ( $0.82 \pm 0.12$  vs.  $0.94 \pm 0.10$ ; Effect Size 0.94) and more relative knee extension power ( $0.31 \pm 0.22$  vs.  $0.20 \pm 0.17$ ; Effect Size 0.54). All other relative extension and flexion powers were similar between the two groups. These results suggest that elite track sprint cyclists differ from sub-elite cyclists in their movement strategy used to generate maximal cycling power. These results suggest that a greater knee extensor contribution could be beneficial with respect to sprinting performance. This finding has practical implications for coaching practice.

### **ELEMENTS OF KINEMATIC ANALYSIS CHARACTERISTIC TO THE RUNWAY RUNNING IN THE MALE TRIPLE JUMP EVENT USING INERTIAL NAVIGATION**

MIHAI, I.

UNIVERSITY OF PITESTI

This work was supported by CNCIS-UEFISCSU, project number PN II-RU code 167/2010 Introduction Implementation of this technology in the human movement analysis enjoys a wide application in studies and research highlighting the effectiveness of this technology Bamberg, (2008); Tilmann, (2008); Hesami, (2008); Billon, (2008); Bidiugan, (2009); Kruger, (2009); Meamarbashi, (2009). The purpose of this study was to examine the speed that may occur in the triple jump event running, the body's center of mass trajectory and the trajectories of ankle and knee joints on the left and right side, using inertial navigation technology. Methods The results were determined using Moven inertial navigation equipment fitted with an inertial sensors system to capture information and send them to the two terminals Xbus through cable connectors. The wireless signal was directed to two receptors that have been connected to a laptop in order to secure the transfer of information and 3D visualization of the movement as a model of the human body consists of 23 segments, hence the data can be stored in a digital form too. Results The center of mass trajectory (as its position) achieved during running, showed values ranging between 0.91 m and 1 m with a standard deviation between 0.03 and 0.06 m. Referring to the ankle joint trajectory, its vertical position on the left versus the right side, we found differences between 0.02 to 0.04 m. In the knee joint trajectory case, the differences between the two sides (right and left) were between 0.01 to 0.02 m. Regarding the speed registered on the runway, it ranged from 7 m/s and 8.9 m/s, its value in conjunction with the center of mass trajectory showing a higher length of the triple jump than in the case of the

higher values (8.9 m/s and 1 m). Discussion Our experiment showed that, decreasing of the running speed has been accompanied by a decreasing of the value of the center of mass trajectory as its position during linear movement. On the other hand, the running speed recorded during the runway showed real influences on the final outcome and this is underlined by studies conducted by Moura (2006), Hay (1992), Jarver, Boas (1984). The small differences between ankle and knee joint position recorded between right and left side shows a good coordination of the lower limbs in the shape of their trajectory which represents a support element in ensuring optimal conditions necessary to acquire a reasonable speed running on the runway. ### KINEMATICAL ANALYSIS ALONG A MAXIMAL LACTATE STEADY STATE SWIMMING TEST

NAZARIO, R., SOUSA, M., FIGUEIREDO, P., RIBEIRO, J., PELARIGO, J., VILAS-BOAS, J.P., FERNANDES, R.  
UNIVERSITY OF PORTO

Introduction: The gold-standard methodology used to assess the athlete's aerobic capacity is the Maximal Lactate Steady State (MLSS) test. In fact, once it determines the highest workload that can be maintained over time without a continual blood lactate accumulation, it can be used to prescribe individualized aerobic training. However, even knowing that swimming performance is influenced both by bioenergetic and biomechanical factors, studies that analysed eventual kinematical changes during the MLSS test are scarce. We aimed to assess the stroking parameters, intracyclic velocity variation (IVV), propelling efficiency, trunk incline (TI) and index of coordination (IdC) along the MLSS test. Methods: A triathlete participant in the World Junior Championship (19yr, 69kg and 1.75m) performed, in subsequent days, 2-4 30min sub-maximal continuous tests at imposed swim pace, with 2.5% differences between trials, to assess the velocity corresponding to MLSS. The test was recorded with two cameras (one under and other above water). Kinematic analysis was made using digitization (APAS) for the trial corresponding to MLSS, being divided in five different points (0, 25, 50, 75 and 100% of the test). Stroke length and stroke rate were computed; swimming efficiency was obtained through IVV that was calculated by the coefficient of variation of the hip's instantaneous velocity (Alberty et al, 2005) and propelling efficiency values (Zamparo et al., 2005); TI was defined by the angle between the shoulder and the hip segment and the horizontal (Zamparo et al., 2009); inter-arm coordination was assessed using the IdC (Chollet et al., 2000). Results: Stroke rate increased (0.50-0.53Hz) and stroke length decreased (2.32-2.21m) along the MLSS test. Propelling efficiency decreased (0.45-0.42) and inter-arm coordination was adapted towards an increased along the 30min with a variation of the values between -19.5 and -13.8%. The TI, as the IVV, presented a constant behaviour along the test (~11° and ~0.26, respectively). Discussion: The inter-cycle changes occurred show the interplay between the variables studied, being self-optimized in a compensatory mechanism to maintain, not only the velocity constant throughout the test, but also the physiological parameters (blood lactate). The only parameters that did not change were the trunk incline, as expected, once it has a good relation with drag, changes on it for the same mean velocity would increase the effort, and probably imbalance the production and removal of blood lactate; and the IVV, since it was suggested that IdC change in order to maintained them (Alberty et al., 2005). ### COMPARISON OF STARTING TECHNIQUES IN CLASSICAL CROSS COUNTRY SKIING SPRINT RACE

LINNAMO, V.1, WILTMANN, W.1, MIKKOLA, J.2, LAAKSONEN, M.S.3, JARVA, O.1, OHTONEN, O.1, HOLMBERG, H.C.3  
1 NEUROMUSCULAR RESEARCH CENTER, DEPARTMENT OF BIOLOGY OF PHYSICAL ACTIVITY, UNIVERSITY OF JYVÄSKYLÄ, FINLAND 2 RESEARCH INSTITUTE OF OLYMPIC SPORTS, JYVÄSKYLÄ, FINLAND 3 SWEDISH WINTER SPORTS RESEARCH

Introduction The start phase of a cross country (XC) sprint race may play a major role later in the race. Some skiers have recently begun to exclusively use double poling (DP) for sprint races enabling them to use skate skis with better gliding properties and longer poles for greater impulses (Nilsson et al. 2004). The present study examined the first 40m of the XC sprint start using the same equipment in diagonal stride (DIA), double poling (DP) or in a combination of the two. Methods After a 15 min warm-up, twelve elite skiers performed nine maximal starts in a random order separated by 4min rest using three different techniques: 1) FREE (subject's free choice), 2) DIA and 3) DP. The total distance was 37.95m, of which the first 17.95m were covered with force plates (Vähäsöyrinki et al. 2008). The horizontal (HI) and vertical (VI) impulses of force from both skis and poles were analyzed in all three conditions. Results The mean time from the start to the first measurement point (FT) was  $4.23 \pm 0.12$ s for FREE,  $4.25 \pm 0.13$ s for DIA and  $4.48 \pm 0.15$ s for DP. The mean time for the total distance (TT) was  $7.28 \pm 0.2$ s for FREE,  $7.23 \pm 0.17$ s for DIA and  $7.67 \pm 0.23$ s for DP. Both FREE and DIA were faster than DP for FT, ST (from 17.95m to 37.95m) and TT ( $p < .05$ ), whereas no significant differences were observed between FREE and DIA. There was no significant difference for the total HI (FREE  $1262 \pm 140$ Ns, DP  $1196 \pm 111$ Ns, DIA  $1295 \pm 94$ Ns) or for the total VI (FREE  $6204 \pm 792$ Ns, DP  $6634 \pm 876$ Ns, DIA  $6156 \pm 543$ Ns) between the conditions. The percentage of total horizontal over total vertical impulse (Hor/Ver) was smaller ( $p < .05$ ) in DP ( $18.3 \pm 2.7\%$ ) than in FREE and DIA ( $20.3 \pm 1.9\%$  and  $21.0 \pm 1.2\%$ ). When combining all the conditions, working contact frequency and total working time showed a negative correlation while HI per working contact time showed a positive correlation with FT, ST and TT ( $p < .05$ ). Discussion Longer poles in DP may lead to faster skiing time in sprint start (Hansen & Losnegard 2010). In the present study with similar equipment, DP was the slowest of the three start techniques. This difference was more pronounced during the first 17.95m, highlighting the importance of the initial section of the start. It seems that FREE and DIA conditions were faster due to the higher force production frequency and a higher Hor/Ver impulse ratio when compared to DP. References Hansen & Losnegard. *Sports Eng* (2010) 12:171-8 Nilsson J et al. *Sports Biomech.* 2003; 2:227-236 Vähäsöyrinki P et al. *Med Sci Sports Exerc* 2008; 40(6):1111-6

### ADOLESCENT PLAYERS SHOULDER MUSCLES ADAPTATION TO TRAINING IN HANDBALL

PONTAGA, I.  
LATVIAN ACADEMY OF SPORTS EDUCATION

Introduction Sport specializations with repeated throwing motions cause increase of the shoulder internal rotator muscles produced torques in a dominant arm, which are much higher than the shoulder external rotator muscles produced torques in comparison with a non-dominant arm muscles (Codine et al, 1997). Imbalance of the shoulder external/ internal rotators strength is the most important etiological factor of the shoulder joint instability (Fleisig et al.). The aims of our investigation were to determine the shoulder rotator cuff muscles produced peak torques values ratio specific to adolescent handball players and to determine the relationship between shoulder internal rotator muscles group's strength and throwing speed in adolescent handball players. Methods The shoulder joint motions in

internal-external rotation are investigated using dynamometers system "REV-9000" (Technogym, Italy). 16 male adolescent handball players with injury – free shoulder joints participated in the investigation. Their mean age was  $14 \pm 1$  years, height  $176 \pm 7$  cm and weight  $63 \pm 10$  kg. The shoulder internal - external rotation isokinetic movements were tested in the plane of scapula at slow ( $60^\circ/\text{s}$ ) and medium ( $90^\circ/\text{s}$ ) angular velocity. The throwing speed was measured by optical equipment "Superschus" (EDV-Beratung Arbeiter, Germany). Results and discussion The difference between the ratios of peak torque values produced by the dominant and non-dominant arms shoulders external/ internal rotator muscles is none significant. The shoulder external/ internal rotators maximal torques ratio for adult handball players is close to 80% (Pontaga, Zidens, 2004). It confirms that the strength of both muscle groups increased proportionally in the training process. This ratio for adolescent athletes is smaller – approximately 70 %. It proves, that additional exercises must be included in the training process to develop the shoulder external rotators muscles. One of the aims of handball training is to increase the throwing speed of players. Clements et al. determined positive correlation between the muscle strength and throwing speed in adolescent baseball players. Their data are in a good agreement with our results demonstrating positive correlation between the shoulder internal rotator muscles developed peak torque at slow ( $60^\circ/\text{s}$ ) and medium ( $90^\circ/\text{s}$ ) movements and the throwing speed in adolescent handball players ( $r = 0,83$  and  $0,76$ , respectively;  $p = 0,0002$ ). ## THE ANALYSIS OF VARIABILITY IN GOLF SWING USING TWO DIFFERENT IRON ON AMATEURS GOLFERS

FERNANDES, O., VAZ, J., BARREIROS, J., ANDREIA, P., BIGLIASSI, M., CASTRO, A.

ÉVORA UNIVERSITY

The analysis of variability in Golf Swing using two different iron on Amateurs golfers Fernandes, O.,Vaz,J.,Barreiros,J.,Andreia,P.,Bigliassi,M.,Castro,A. Évora University Introduction: Golf Swing (GS) is a complex sequential actions involving rotation of the hips, trunk, and shoulder. The key of a good movement in GS is the timing of the involvement of all body segments to produce maximum speed and accuracy of the club at impact. Many golfers' instructors and professional players refer the importance of rhythm during the GS. The elite performers have developed a pattern of movement that produces the movement at high speed. The consistence on GS is very important to accuracy and speed, and many amateur golfers' have poor consistence regarding the time on different phases in GS. Bernstein (1967) said that Human Movement presents variability from trial to trial. Variability is pervasive throughout the multiple levels of movement organization and occurs both within and between individuals. The purpose of this study was to examine the variability within and between amateur golfers performing 16 GS with two different iron clubs (Pitch and 4-iron). Methods: Ten amateurs golfers volunteered to participate in this study. All participants signed an informed consent approved by the Review Board .The subjects were asked to perform a GS using two different clubs. The pitch shots is use to produce a higher trajectory and the 4-iron is used for longer distances. All subjects repeated 10 times for each iron. To analyze the time variability we determined the time between the follow 5 instants of the GS at (sBS)– start of back swing; (sFS)–start of forward Swing; (hFS) – horizontal position of the club in forward Swing; (iB) – ball impact and (hFT)– horizontal position of the iron at follow-through. The time between those instants were measured and compared to analyze inter and intra individuals variability. Results: The results from different swing from the Pich the results shows similar variation – [sBS- sFS] -  $954,2 \pm 272,8$  ms; [sFS- hFS] -  $231,2 \pm 61,2$  ms; [hFS- iB] -  $49,9 \pm 14,1$  ms; ; [iB-hFT] -  $63,2 \pm 17,6$  ms; the 4-iron the results show the same variation [sBS- sFS] was  $969,2 \pm 294,0$  ms; [sFS- hFS] -  $230,8 \pm 60,4$  ms; [hFS- iB] was  $49,0 \pm 13,6$  ms; ; [iB-hFT] -  $72,3 \pm 81,1$  ms. The One-Way ANOVA revealed no significant difference between this two different swing. Discussion: The main aim of this study was to analyze the variability on two different iron in GS. This results show some pattern in GS Conclusion: We conclude that the amateurs golfers don't change the technique of the GS and they show the same variability pattern even they use different iron.

## DIFFERENCES IN KINEMATICS BETWEEN INDOOR AND BEACH VOLLEYBALL OVERHAND PASS

WAGNER, H., WENDLING, I., MÜLLER, E.

UNIVERSITY OF SALZBURG

DIFFERENCES IN KINEMATICS BETWEEN INDOOR AND BEACH VOLLEYBALL OVERHAND PASS Wagner, H.1,2, Wendling, I.1, Müller, E.1,2 1: SSK (Salzburg, Austria), 2: CDLBS (Salzburg, Austria) Introduction The overhand pass is the most applied passing technique in indoor volleyball. Beach volleyball players often use the forearm instead of the overhand pass because of the risk of a technical error due to an incorrect movement, although the overhand pass is more precise (Koch & Tilp, 2009). Hernandez et al. (2004) analyzed kinematics of the overhand pass in indoor volleyball; however, a kinematic analysis of the overhand pass in beach volleyball is lacking. The aim of the study was to analyze kinematic differences between the indoor and beach volleyball overhand pass. Methods Elite indoor ( $n=9$ ) and beach ( $n=9$ ) volleyball players had to perform 20 overhand passes under standardized conditions and were instructed to play the ball into a basketball basket. 3D-kinematics were measured using an 8 camera Vicon MX13 motion capture system (250 Hz) and a Basler high speed camera (125 Hz). Passing precision was determined by using a special point system (ball inside or outside the basket with or without touching the rim). Differences in kinematic parameters and passing precision were calculated with an independent t-test. Bonferroni-correction was calculated and significance was set at  $P < 0.004$  for  $n=14$  variables. Results In beach volleyball ball, contact time in the overhand pass increased (+52ms) in comparison to indoor volleyball. In the kinematic parameters, significant differences ( $P < 0.004$ ) between indoor and beach volleyball were found in the elbow flexion and shoulder abduction angle at first ball contact, the maximal elbow flexion and shoulder internal rotation angle and the shoulder abduction angle at ball release. No significant differences were found in the forearm pronation angle and passing precision. Discussion The differences between indoor and beach volleyball overhand pass can be explained by tactical components of the game. In indoor volleyball, the setter tries to mask the setting direction in the overhand pass (4-5 players could strike the ball). The ball is played over the head, with short contact time and less range of motion. In beach volleyball, it is not possible to mask the setting direction because there is only one player who can strike the ball. Therefore, it is more important to control the ball and to prevent rotation of the ball after release. The beach volleyball overhand pass is characterized by longer contact time due to a higher range of motion in the elbow flexion, shoulder abduction and shoulder internal rotation. The results of the study could assist coaches and beach volleyball players to optimize the overhand pass; however, additional training studies are warranted. ### PP-BN02 Cognitive Performance

#### INFLUENCE OF ENERGETIC PHOSPHATES ON COGNITIVE PERFORMANCE

MIERAU, J., HOLLMANN, W., MIERAU, A., STRÜDER, H.K.

GERMAN SPORT UNIVERSITY COLOGNE

**Introduction** The current study examined the effects of oral creatine supplementation on cognitive and psychomotor performance in the young and the elderly. Creatine supplementation is well known to enhance physical performance, and has been used successfully in the treatment of neurological and neuromuscular disease (Kreider 2003). In terms of energy turnover, the neurons of the human brain function similar to the cell in the skeletal muscle tissue. Studies have shown an increased mental fatigue-resistance after oral creatine supplementation, as well as positive effects on working memory and intelligence of young vegetarian subjects (Rae et al. 2003). These results suggest that creatine concentration in the cell might influence not only physical, but also cognitive performance. **Methods** Using a double blind placebo-controlled cross over design the subjects supplemented 5 grams of creatine-monohydrate and placebo for 6 weeks with 6 weeks wash-out period between the two treatments. 24 subjects (11 old and 13 young) volunteered to participate in the study. The old subjects (3 male and 8 female) aged  $69.5 \pm 5.8$  years, whereas the young subjects (9 male and 4 female) aged  $26.4 \pm 2.8$  years. The Vienna Test System (VTS), a computerized psychological assessment tool, was used in order to measure cognitive performance. The following components of cognition were examined: long-term selective attention (Signal-Detection Task), non-verbal intelligence and especially logical reasoning (Raven's Standard Progressive Matrices), memory performance (Continuous Visual Recognition Task) and cognitive speed concerning perception, processing and motor response (Simple Reaction Task). **Results** The serum concentration of creatine, creatinine and the creatine/creatinine quotient increased after creatine supplementation, decreased back to baseline values after the wash-out period and remained unchanged after placebo supplementation. Thus, the supplementation design used has proven itself. Statistical analyses yielded no effects of creatine supplementation on cognitive performance. **Conclusions** Combined with the literature, the results of the present study suggest that artificial creatine supplementation may play an important role for muscular and central functions. However, creatine supplementation might be less effective in healthy subjects compared to patients with cerebral abnormalities, vegetarians and/or those who suffer from low cerebral creatine concentration. **References** Kreider RB. #### EXERCISE AND COGNITIVE FUNCTION IN ADOLESCENT SCHOOL CHILDREN

COOPER, S.B., BANDELOW, S., NUTE, M.L., MORRIS, J.G., BOWMER, J., NEVILL, M.E.

LOUGHBOROUGH UNIVERSITY

**Introduction** There is considerable evidence that a bout of exercise enhances cognitive function in adults (Brisswalter et al, 2002) and children (Sibley and Etnier, 2003). However, the acute effects of a bout of exercise on cognitive function in an adolescent population are less clear. **Methods** With the institutions ethical advisory committee approval, 45 male and female adolescents (12 to 13 years old) participated in the study. The study employed a randomised crossover design, with 2 main trials (exercise and resting) separated by 7 days. Participants consumed the same meal the evening before each main trial and the same, self-selected, breakfast on the morning of each trial. 60 min after breakfast, participants completed a bout of exercise (exercise trial) or continued to rest (resting trial). The exercise bout consisted of 10 repeats of level 1 of the multi-stage fitness test, with 30 seconds rest between repeats. Participants' heart rate was recorded during the rest period and if heart rate reached 190 beats.min<sup>-1</sup>, participants walked for the remainder of the exercise. A battery of cognitive function tests (Visual search test, Stroop test, Sternberg paradigm and Flanker task) were completed 30 and 120 min following breakfast. **Results** When examining response times of correct responses, there was a greater improvement in response times across the morning following the exercise bout when compared to the resting trial, on the Sternberg paradigm ( $t=2.5$ ,  $p=0.011$ ) and Flanker task ( $t=3.5$ ,  $p=0.001$ ). There was also a greater improvement in response times across the morning following the exercise on the visual search test, though this effect was specific to the more complex level ( $t=2.6$ ,  $p=0.008$ ). When examining the accuracy of responses, there was a tendency for participants to achieve a greater proportion of correct responses on the exercise trial compared to the resting trial on the visual search test ( $z=1.9$ ,  $p=0.052$ ). However, there was no effect of the mid morning bout of exercise on response accuracy during the other tests (Stroop test, Sternberg paradigm and Flanker task). **Discussion** Overall, these results suggest that a mid morning bout of exercise improves adolescents cognitive function, when compared with continuing to rest. Completing a mid-morning bout of exercise appears to have a greater effect on the speed of responses (i.e. response times), compared to the accuracy of responses. However, the improvement in response times is not to the detriment of accuracy, thus we conclude that overall there is an improvement in adolescents' cognitive function following a mid-morning bout of exercise. **References** Brisswalter J, Collardeau M, René A. #### COMPENSATORY RESPONSE OF THE RIGHT PREFRONTAL CORTEX IN THE DEVELOPMENT OF EXERCISE-ENHANCED STROOP PERFORMANCES IN THE ELDERLY: A FUNCTIONAL NEAR-INFRARED SPECTROSCOPY STUDY.

HYODO, K.I, SUWABE, K.I, DAN, I.2, SOYA, H.I

1: UNIVERSITY OF TSUKUBA (IBARAKI, JAPAN), 2: JICHI MEDICAL UNIVERSITY (TOCHIGI, JAPAN)

**Introduction** Recently there have been many reports stating that regular exercise enhances brain function in elderly people. However, due to several adventitious effects, the exact neural substrate behind it is still controversial. To address this issue, an acute exercise model should be established. We thus applied functional NIRS and revealed an acute bout of moderate exercise enhanced activation of the left dorsolateral prefrontal cortex (l-DLPFC) due to Stroop interference (SI) and improved the Stroop performance in young adults (Yanagisawa et al., 2010). However, it is unclear whether it is the same in the elderly. In some task situations, the elderly may recruit the contralateral hemisphere to compensate for decreased task-specific activation of brain loci (Park et al., 2009). We thus aimed to clarify whether these acute exercise effects were reproducible in the elderly, and if so, whether the activity of the l-DLPFC or compensatory function is involved in the enhanced executive function. **Methods** Sixteen healthy elderly participated in the study. Before and after 10 minutes of exercise on a cycle ergometer at a moderate intensity corresponding to their ventilatory threshold, they performed a color-word Stroop task (CWST) that

consisted of incongruent and neutral conditions. Cognitive performance was assessed by reaction time (RT). Brain activity was monitored with fNIRS during the CWST. The fNIRS probes were set to cover LPFC activation. Spatial analysis was performed by using virtual registration (Tsuzuki et al., 2007). Changes in oxy-Hb concentration were used for statistical analysis. The difference between conditions (Incongruent - neutral) was calculated as SI to determine executive control. All subjects underwent a control experiment (Con) on a separate day in which they rested instead of exercising. Results An acute moderate exercise significantly improved SI as measured by RT compared to Con. In fNIRS data, we detected brain activation due to SI in the LPFC in both hemispheres. Compared to Con, this SI-related activation was significantly enhanced in the right frontal pole (r-FP) due to the acute moderate exercise. The enhanced activation significantly coincided with improved cognitive performance. Discussion Here we found that an acute moderate exercise enhances the ability to cope with SI through the increased activation of the r-FP. In the elderly, exercise-elicited improvement of executive functions was reproduced, but the responsible brain loci were different compared to the young. The current study suggests that with aging some contralateral brain loci such as r-FP should be exercise responsive area to be involved in the development of enhanced cognitive performance for the deteriorated activities of the l-DLPFC. ### **NORMALIZING EFFECTS OF ACUTE MODERATE EXERCISE ON DEPRESSED MOOD AND THE COGNITIVE DECLINE INDUCED BY NEGATIVE EMOTIONAL STRESS.**

AKAHORI, M., YAMADA, Y., IDE, K., SOYA, H.

UNIVERSITY OF TSUKUBA

Introduction Recently, the growing number of people with mood disturbances such as depression and anxiety has become a serious social problem. In those patients, neuronal activity in the prefrontal cortex is attenuated, especially in the dorsolateral prefrontal cortex (DLPFC) involved in cognitive functions and emotion (Okada et al., 2003). However in healthy adults an acute bout of moderate exercise enhances the activity of the DLPFC (Yanagisawa et al., 2009), suggesting a possible beneficial role of moderate exercise restoring mood and cognitive functions. To test this hypothesis, we examined whether acute moderate exercise affects depressed mood and the cognitive decline induced by negative emotional stress. Methods We used young adults subjects (n=13). They are subjected to three sessions of experiments on three separate days in random order. They were given negative emotional stress for 10 minutes by visual stimulus (VS) using pictures from the International Affective Picture System and neutral VS as a control. Following the negative VS they had a five-minute rest or exercised on a cycle ergometer at a predetermined ventilatory threshold. After the rest or exercise they had another five minutes of rest or recovery and then performed a color-word Stroop task (CWST). Reaction time (RT) was examined in the CWST to assess cognitive performance. Neural activation during the CWST was evaluated by changes in oxy-hemoglobin (oxy-Hb) as determined by fNIRS. The region of interest in this study was the left DLPFC. Changes in mood were evaluated before and after VS and after exercise using a two-dimensional mood scale (TDMS). Results Mood significantly declined after viewing negative VS and it remained lower after the 10-minute rest compared to 10 minutes after the neutral stimulus. On the other hand, mood that declined after viewing negative VS was normalized after exercise. RT was significantly delayed after the 10-minute rest following negative VS compared to the other experiments while there were no significant differences between other two experiments. In the left DLPFC, oxy-Hb was significantly lower after the 10-minute rest following negative VS compared to that after the neutral VS. oxy-Hb after the exercise following negative VS was highly restored compared to that following neutral VS. Discussion We found that moderate exercise can normalize mood and cognition from a declined condition caused by negative emotional stress from negative VS. The current study is the first report showing that moderate exercise has a rescue effect on a stressful condition. This suggests that exercising at moderate intensity is beneficial for people in a stressful society to keep their mental health to be well. DECISION-MAKING AND ANTICIPATION IN SPORT: THE UNDERLYING PROCESSES OF SUPERIOR PERFORMANCE Roca, A.1, Ford, P.R.1, McRobert, A.P.1, Williams, A.M.1, 2 1: Liverpool John Moores University, UK, 2: The University of Sydney, Australia Introduction The ability of skilled athletes to anticipate the actions of others and to make appropriate decisions under time constraints differentiates them from lesser skilled athletes (Williams, et al. 2010). These judgments are selected via underlying visual and cognitive processes, which likely differ between skill groups. The aim in this study was to examine the processes underlying superior judgment performance in soccer players using representative simulations. Skill-based differences were expected for all judgment and process measures. Methods Skilled (n = 24) and less-skilled (n = 24) adult soccer players interacted with 20 life-size, video sequences involving 11 vs. 11 soccer situations filmed from the perspective of a central defender and occluded at a key moment. Situations either started with the ball being located in the participants' offensive (i.e. far situation) or defensive half of the pitch (i.e. near situation). The ability of participants to anticipate the intentions of opponents and to select their own actions was measured across two experiments. In Experiment 1, visual search processes were examined using an eye-movement registration system. In Experiment 2, cognitive processes were examined using retrospective verbal reports. Results Skilled players anticipated the actions of opponents correctly on 69% of the situations and decided on an appropriate action to execute on 82% of occasions, compared to 36% and 50% for the less-skilled, respectively. During the far task, skilled players made an average of 15 visual fixations of 320ms duration to many locations in the display, whereas the less-skilled made fewer fixations of shorter duration (7 fixations for 792ms). During the near task, skilled players made 8 fixations of 598ms duration mainly toward the player in possession of the ball compared to the lower 6 fixations of 877ms used by the less-skilled players. Less-skilled players mostly fixated the player in possession and the ball. Skilled players made 7 verbal report statements per situation with a higher proportion categorized as predicting future events, planning future actions, and evaluating events compared to the less-skilled players, who made 5 statements per situation that were mainly categorized as monitoring events. Discussion Skilled players' superior judgment performance was underpinned by quantitatively different task-specific underlying visual and cognitive processes, which may indicate they have more advanced domain-specific memory representations, when compared to the less-skilled. A number of theoretical and practical implications are discussed. References Williams, A.M., Ford, P.R., Eccles, D.W., & Ward, P. (2010). *Appl Cogn Psychol*, n/a. doi: 10.1002/acp.1710

## THE EFFECTS OF EXERCISE INTENSITY ON CRAVING AND VISUAL ATTENTIONAL BIAS FOR SNACKS AMONG TEMPO-RARILY ABSTINENT SMOKERS

OH, H., TAYLOR, A.H.

UNIVERSITY OF EXETER

**Introduction** Substantial weight gain after smoking cessation is partly due to increased energy intake from comfort snacking (Spring et al., 2009). Moderate intensity exercise acutely reduces food craving (Taylor & Oliver, 2009) and visual attentional bias (AB) to food images (Taylor et al., 2009) among non-smokers. It is unknown if exercise, of different intensities, acutely reduces food cravings and AB to video clips of snacks among abstinent smokers. **Methods** 15 male and 8 female regular snackers, age  $23.9 \pm 4.8$  yrs, BMI  $23.5 \pm 2.9$ , abstained from smoking for 15 hrs, and eating for 2 hrs. They were randomly assigned to engage in each of three 15 min treatment conditions (on separate days): moderate and vigorous intensity cycling and rest. AB was assessed using an eye tracker (Pan/Tilt Model 504, ASL, USA) pre and post-treatment at each session. Participants watched 8 randomly presented pairs of food/neutral 7 sec video clips and data was derived for % of first fixation (initial AB) and % of total dwell time (maintained AB) on the food image. Self-reported food craving (modified FCQ-S, Cepeda-Benito et al., 2000) was assessed pre, mid and post-treatment. Results Fully repeated ANOVAs revealed a condition x time interaction for food cravings ( $F(5, 5.5) = 10.7, p < .001$ ).  $t$  tests revealed that at mid- and post-treatment food cravings were significantly lower after vigorous exercise, compared with rest and moderate exercise. Fully repeated ANOVAs revealed condition x time interactions for the AB measures of % of first fixation ( $F(2,44) = 8.1, p < .001$ ) and % of dwell time ( $F(2,4) = 5.1, p < .01$ ). Post-hoc  $t$ -tests (with Bonferroni correction) revealed a significant reduction for % of first fixation from pre to post moderate ( $t(22) = 3.0, p = .006, 95\% \text{ CI } 6.7 \text{ to } 35.4, ES d = .77$ ) and vigorous exercise ( $t(22) = 2.6, p = .016, 95\% \text{ CI } 3.3 \text{ to } 28.5, ES d = .68$ ). Compared with the rest condition, % of dwell time was significantly lower after vigorous exercise at post-treatment ( $t(22) = 3.3, p = .003$ ). **Discussion** Research shows that exercise reduces cigarette cravings and AB (to smoking images) during nicotine abstinence. This study also shows that exercise can reduce food cravings and AB to snacking cues among abstinent smokers. Both moderate and vigorous exercise reduced initial AB, whereas only vigorous reduced maintained AB. Short bouts of exercise may be useful for abstaining smokers to self-regulate snacking. **References** Cepeda-Benito A, Gleaves DH, Fernandez MC, Vila J, Williams TL, Reynose J. ## IMPACT OF NON-FUNCTIONAL OVERREACHING ON COGNITIVE PERFORMANCES.

DUPUY, O., LUSSIER, M., FRASER, S., LAGUË-BEAUVAIS, M., BHERER, L., AUDIFFREN, M., BOSQUET, L.

UNIVERSITY OF POITIERS - UNIVERSITY OF MONTREAL - UNIVERSITY OF QUEBEC AT MONTREAL

**Introduction** Peak performance in sport requires training loads that will occasionally push human body adaptation possibilities to their limits. Overtraining syndrome (OTS) is an important menace on performances and health in athletes. OTS results when appears an imbalance between the training and/or not training stress and sufficient recovery, which could lead to an unexplained underperformance. Functional Overreaching (FOR) and Non Functional Overreaching (NFOR) are physical states reached just before OTS on the continuum, but the line between the two is very thin. It is therefore very important to validate markers to prevent the development of NFOR. It has been recently proposed that psychomotor speed might be such a marker. The aim of this study was to investigate whether cognitive performance was altered by a two-week of overload training. **Method** Twelve well-trained men participated in this study. The protocol consisted in increasing their training load of 100% for two weeks and thereafter to decrease by 50% for one week. Before and after this period of overload and after the period of taper, the participants performed a maximal graded exercise test, a constant intensity test (85% of peak treadmill speed), and a computerized version of the Stroop color word-test. They also filled out the Profile Of Mood States (POMS). During the pre and post-test evaluations, participants trained at their usual training load. Results Prior to data analysis, all the participants were qualified as overreached. After the overload period, participants decreased their physical performance ( $29 \pm 9$  to  $21.6 \pm 10$  min,  $p < .05$ ) and their "energy index" (ie. vigor – fatigue in the POMS,  $120 \pm 14$  to  $98 \pm 16$ ,  $p < .05$ ). After the taper, the physical performance and the energy index returned ( $p < .05$ ) to baseline. Regarding the cognitive performance, the same pattern was observed as participants' reaction times increased from before to after the overload period ( $816.3 \pm 30.8$  to  $892.3 \pm 40.1$ ,  $p < .05$ ) and, then return to baseline values after the taper ( $p < .05$ ). **Conclusion** An unaccustomed increase in training volume which is accompanied by a decrement in physical performance induces a decline in cognitive performance. Stroop color word-test has therefore the potential to be a valid marker of overreaching.

## EFFECT OF HIGH INTENSITY INTERMITTENT EXERCISE ON COGNITIVE PERFORMANCES.

DUPUY, O., LUSSIER, M., RENAUD, M., BHERER, L., AUDIFFREN, M., BOSQUET, L.

UNIVERSITY OF POITIERS - UNIVERSITY OF MONTREAL - UNIVERSITY OF QUEBEC AT MONTREAL

**Introduction** It has been proposed that psychomotor speed and cognitive performance represent a potential marker of non-functional overreaching and/or overtraining. This hypothesis has been recently confirmed in the study by Dupuy et al [1], who reported an altered cognitive performance in endurance athlete classified as overreached. It's now important to describe the effect of a single bout of exercise in order to distinguish the effect of acute fatigue to chronic fatigue on cognitive function. Indeed, acute fatigue induced by a training session and non-functional overreaching are on the same continuum. The aim of this study was therefore to evaluate the temporal effect of a high intensity intermittent exercise on different cognitive process. **Method** Twenty one healthy men participated in this study. They performed a maximal graded exercise test to determine peak treadmill speed. In a second time, the experimental group ( $n=13$ ) performed a series of six consecutive 180s runs at 95% of PTS, with 180s of passive recovery. A computerized version of the Stroop color word-test was administrated during four consecutive days, the first morning (baseline) of this protocol, 1h after the intermittent exercise, 24h, 48h and 72h after the baseline measure. The group control ( $n=8$ ) realized the same protocol without the high intensity intermittent exercise. The Stroop color word-test includes 2 conditions of non-executives function (congruent and denomination) and 2 conditions of executives functions (interference and switching). Each of the 4 blocks contained 60 trials. Results With regard to the effect of Stroop color word-test practice, a main effect of Session for both measures and for both groups,  $p < .05$ , was observed. However, no significant interactions were observed between experimental and control group at any moment during the protocol. **Conclusion** The main result was that acute fatigue induced by a high intensity intermittent exercise session have no effect on the cognitive process assessed in this study. So, in order to prevent non-functional overreaching or overtraining, the administration of cognitive task can be proposed from 1h recovery

after a training session. 1. Dupuy, O., M. Renaud, L. Bherer, and L. Bosquet, Effect of Functional Overreaching on Executive Functions. *Int J Sports Med*, 2010. 31 (9): p. 617-623.

### SPORTS VISION SKILLS AND INJURY INCIDENCE RELATION IN AMATEUR SOCCER PLAYERS

OZKAYA, G.1, OZKAYA, C.2, KARAHAN, M.3

1MARMARA UNIVERSITY, TURKEY; 2ACIBADEM UNIVERSITY, TURKEY; 3MARMARA UNIVERSITY, TURKEY.

**Introduction** The demands on the visual system during athletic performance are among the most rigorous of any activity. Because vision influences the capacity of an athlete to perform the tasks of a sport, scientific research has been performed to investigate the link between skill and vision. Visual system is highly related with proprioceptive system and these systems are affecting mechanism of injuries. **Methods** 30 subjects (15 injured soccer players and 15 non-injured soccer players) with an average of  $22 \pm 0.93$  and  $22 \pm 0.80$  respectively. We measured visual concentration (VC) with tachistoscope, eye-hand coordination (EHC) with LaFayette Eye-Hand Coordination Model 58024A, both hand coordination (BHC) with LaFayette Two-Arm Coordination Model 32532 and anticipation time (AT) with LaFayette Bassin Anticipation Timer Model 35575. Data were collected with a questionnaire named Nordic Questionnaire for the analysis of musculoskeletal symptoms in last 12 months. SPSS 14 were used for statistical measurements and correlations between incidence of injury and VC, EHC, BHC, AT. Results Injured soccer players have completed all tests with more mistakes and time scores. There were statistical significant differences of EHC, BHC and AT measurements between injured and non-injured soccer players ( $p < 0.05$ ). No statistical significant difference was observed for VC. **Discussion** All tests used in this study required several levels of visual skills and in this study we aimed to focus on early visual-processing stage of the sensory-guided behavior. In our study we revealed an association between several visio-motor tests and frequency of injuries in soccer-players. It was reported that elite athletes have better visual skills (3) and we propose that this might also be related with fewer non-contact injuries. Therefore, we are planning further studies about influence of sports vision on sports injuries. **References** 1) Agel J, Evans TA, Dick R, Putukian M, Marshall SW. (2007). ### EFFECT OF REACTION TIME IN VISUAL RESPONSE TRAINING

YOTANI, K., TAMAKI, H., KIRIMOTO, H., YUKI, A., KITADA, K., OGITA, F., TAKEKURA, H.

NATIONAL INSTITUTE OF FITNESS AND SPORTS IN KANOYA, NIIGATA UNIVERSITY OF HEALTH AND WELFARE, AICHI UNIVERSITY OF EDUCATION, ISHIKAWA NATIONAL COLLEGE OF TECHNOLOGY

**Purpose:** The latency of motor-evoked potentials (MEPs) reflects the neural conduction time between the motor cortex and corresponding muscle, and can be recorded using transcranial magnetic stimulation (TMS). Moreover, visuo-motor related time (VMRT) can be calculated by subtracting MEP latency from pre-motor time in simple-reaction time using electromyography (EMG) (Yotani et al., 2009). We conducted response training to visual stimulus, and assessed the effects on reaction time of different periods or frequencies of training. **Method:** Fourteen healthy male subjects participated in the present study (mean age  $21 \pm 2$ ), and were randomly divided into two training groups: 4-week training (4W,  $n=7$ ) and 8-week training (8W,  $n=7$ ). Each group conducted the same response training for 2 days/week (4W) or 1 day/week (8W), and performed the same reaction time test before (Pre-test) and after (Post-test) the training. The training and test employed a mastication task. The task comprised 10 trials performed as quickly as possible in response to visual stimulation from a flashing light, and was repeated 5 times with a 2-3 min rest between each task during training. The EMG signal was recorded from the right masseter muscle simultaneously with the light signal. MEP latency was measured from the masseter muscle using TMS. Pre-motor time (PMT), visuo-motor related time (VMRT), and MEP latency (MEPL) were measured in the tests. In addition, each group performed the same test after detraining for 8 weeks (De-test). **Results:** PMT and VMRT were in both groups significantly shorter at Post-test than at Pre-test ( $P < 0.01$ ), and the tendency toward reduction in VMRT was comparable in the 4W and 8W groups. MEPL in neither group exhibited a significant difference between the tests. After 8 weeks of detraining, PMT, VMRT, and MEPL in the 8W group did not differ significantly between Post-test and De-test. However, the 4W group exhibited significant differences in PMT, especially VMRT, between Post-test and De-test ( $P < 0.05$ ). **Discussion/Conclusion:** The results of the present study suggest that VMRT shortens equivalently between Pre- and Post-test regardless of difference in response-training frequency. Training effect was in fact maintained for a longer time in the 8W group than in the 4W group. **References:** Yotani K, Tamaki H., Sakashita I., Yuki A., Kirimoto H., Kitada K., Ogita F., Takekura H. (2009). Reaction time analysis for kendo strikes in response to light signals using electromyography and a transcranial magnetic stimulator. *Book of Abstracts, 14th Annual Congress of ECSS*: 371-372.

### EFFECTS OF ACUTE EXERCISE AND TADALAFIL ADMINISTRATION ON ATTENTIONAL PERFORMANCE

GALLOTTA, M.C., EMERENZIANI, G.P., FRANCIOSI, E., BONAVALONTÀ, V., DI LUIGI, L., GUIDETTI, L., BALDARI, C.

UNIVERSITY OF ROME FORO ITALICO

**Introduction** Given the therapeutic and non-therapeutic use of the tadalafil, (phosphodiesterase-5 inhibitor, PDE-5i), we examined its immediate effects combined with acute exercise on mental performance, such as attention, speed and accuracy. **Methods** Twelve well-trained subjects ( $24.4 \pm 2.2$  years of age) reported to the laboratory on four occasions. They performed a maximal exercise test in normoxia and 30 min of ergometer cycling at individual anaerobic threshold, after which they received a single oral administration of tadalafil or placebo in a randomized order. Mental performance was measured prior (Pre) and immediately after (Post) the four experimental sessions using the d2-test (Brickenkamp, 2002). The total number of items processed (TN) within the d2-test, the percentage of errors (E%), and the concentration performance (CP) were calculated and used as a parameter for sustained attention and concentration. TN value was a quantitative measure of the working speed, E% was a qualitative measure of performance, representing the proportion of errors made within the area of all items processed, and CP was an objective measure of concentration, representing the number of the correct responses minus the errors. **Results** The TN and the E% absolute variation ( $\Delta$ ) with respect to the Pre values (POST value – PRE value) did not significantly change in the four experimental conditions, while the CP absolute variation was significantly higher in VO<sub>2</sub>max exercise condition than in IAT exercise condition ( $p < 0.05$ ), independently by the type of administration (tadalafil or placebo). **Discussion** The primary finding of this investigation was that the administration of a single dose of a long-term PDE-5i did not influence the mental perfor-

mance. However, results demonstrated a major increase of the concentration performance due to maximal exercise. References Brickenkamp R, Zillmer E (1998). The d2 test of attention. Seattle-Toronto-Bern-Göttingen: Hogrefe and Huber Publishers.

## COGNITIVE AND COGNITIVE-MOTOR INTERVENTIONS AFFECTING MOTOR FUNCTIONING OF OLDER ADULTS: A SYSTEMATIC REVIEW

PICHIERRI, G., WOLF, P., MURER, K., DE BRUIN, E.D.

ETH ZÜRICH

**COGNITIVE AND COGNITIVE-MOTOR INTERVENTIONS AFFECTING MOTOR FUNCTIONING OF OLDER ADULTS: A SYSTEMATIC REVIEW** Pichierri, G., Wolf, P., Murer, K., de Bruin, E.D. 1: IBWS ETH (Zurich, Switzerland), 2: SMS-Lab ETH (Zurich, Switzerland) Introduction Several types of isolated cognitive or combined cognitive-motor intervention types that might influence physical functions have been proposed in the past; training of dual-tasking abilities, and improving cognitive function through behavioral interventions or the use of computer games (Yogev-Seligman et al., 2008; de Bruin et al., 2010). The objective of this systematic review was to examine the literature regarding the use of cognitive and cognitive-motor interventions to improve motor skills in older adults or people with cognitive impairments. The aim was to identify potentially promising methods that might be used in future intervention type studies for older adults. Methods A systematic search was conducted for the Medline/Premedline, PsycINFO, CINAHL and EMBASE databases. The search was focused on older adults and adult patients with brain injuries or cognitive impairments. The search was restricted to English, German and French language literature without any limitation of publication date or restriction by study design. Cognitive or cognitive-motor interventions were defined as dual-tasking, mental imagery, virtual reality exercise, cognitive exercise, or a combination of these. Results 28 articles met our inclusion criteria. Three articles used an isolated cognitive intervention strategy, seven articles used a dual-task strategy and 19 applied a computerized game-like strategy. There is evidence to suggest that cognitive or motor-cognitive methods positively affects motor functions, such as postural control, walking abilities and general functions of the upper respectively lower extremities. The majority of the included studies resulted in improvements of the assessed functional outcome measures. Discussion The current evidence on the effectiveness of cognitive or motor-cognitive interventions to improve motor functions in older adults or people with cognitive impairments is limited. The heterogeneity of the studies published so far does not allow defining the training methodology with the greatest effectiveness. This review nevertheless provides important foundational information in order to encourage further development of novel cognitive or cognitive-motor interventions, preferably with a randomized control design. Future research that aims to examine the relation between improvements in cognitive skills and the translation to better performance on selected physical tasks should explicitly take the relation between the cognitive and physical skills into account. ## PHYSICAL ACTIVITY, PHYSICAL EXERCISE AND COGNITIVE FUNCTION

DI BLASIO, A., BUCCI, I., DI DONATO, F., IZZICUPO, P., D'ANGELO, E., TAGLIERI, M.G., RIPARI, P., NAPOLITANO, G.

CHIETI-PESCARA UNIVERSITY

**Introduction** Cognitive performance has been shown to decline as a function of aging, as have the brain regions that support it. Menopause is linked with both hormonal and metabolic changes and with an increased risk of cerebrovascular disease, negatively affecting the structures and the functions of the brain. Both physical activity and physical exercise have positive effects on cognitive function. The aim of our study was to investigate the influencing variables of cognition and the effect of 14 weeks of aerobic training in post-menopause. **Methods** Fifty-four post-menopausal women ( $57.54 \pm 4.95$  yrs) without history of diabetes mellitus, cognitive, cardiovascular and cerebrovascular diseases were enrolled in the study. Women did not participate in physical exercise program during the two years prior to the study and nobody had hormone-replacement therapy. Digit Span Test, and both part A (TMT-A) and part B (TMT-B) of the Trail Making Test assessed cognitive performance. Body composition was assessed by electrical bioimpedance technique, while SenseWear Pro3 Armband measured daily physical activity characteristics. The device gives information about total daily energy expenditure, mean intensity of daily physical activities, and both time and energy spent on physical activities with intensity > 3 METs. By our software, we calculated the daily numbers of bouts of physical activities performed at moderate intensities and lasting almost 5 (B5) and 10 (B10) consecutive minutes. Plasma lipoproteins were also measured. A dietician assessed dietary habits. Women walked 4 days/wk, for 14 weeks, at moderate intensity. **Results** Cluster analysis, performed on basal results of forward (FW) and backward (BK) scores and on TMT-A and TMT-B, identified two sub-groups: GROUP+ (n=26) and GROUP- (n=28). GROUP+ had better cognitive performance than GROUP-. Student's t-test showed that sub-groups differed for B10 ( $p=0.012$ ), total cholesterol (TC) ( $p=0.049$ ), LDL-cholesterol ( $p=0.031$ ), triglycerides ( $p=0.011$ ) and TC to HDL-cholesterol ratio ( $p=0.011$ ). Logistic regression indicated that both B10 ( $B=-0.255$ ;  $p=0.050$ ) and TC to HDL-cholesterol ( $B=0.669$ ;  $p=0.025$ ) predicted sub-group membership. RM-ANOVA showed that after the training both sub-groups improved TMT-A ( $F=9.959$ ;  $p=0.003$ ), FW ( $F=11.176$ ;  $p=0.002$ ) and digit span score ( $F=12.615$ ;  $p=0.001$ ). **Discussion** Quali-quantitative characteristic of spontaneous physical activity (i.e. B10) is important for cognitive performance of post-menopausal women that do not engage physical exercise. Fourteen weeks of aerobic training has been found linked with the improvement of working memory and visual attention.

#### THE EFFECT OF AN 8-WEEK PROGRESSIVE HIP FLEXIBILITY PROGRAMME ON RUNNING TECHNIQUE IN TRIATHLETES.

SCARFE, A.C., HENEGHAN, N.R., CONNICK, M.J., LI, F.X.

UNIVERSITY OF BIRMINGHAM

**Introduction** When compared to runners, triathletes exhibit decreased stride length, hip range of motion (ROM) and thigh extension during running (Connick and Li, under review). The cycling training undertaken by triathletes, is carried out in a relatively flexed posture, and may result in a chronic shortening of the hip flexors. Subsequently this may account for the observed reduced static and dynamic hip ROM found in triathletes (Scarfe, 2010). It is well publicised that static ROM can be increased by a flexibility programme (Winters, 2004). The aim of this study was to test whether increasing static hip ROM can change triathlete running kinematics. **Methods** Following a 4 week control period, 9 male triathletes completed an 8-week flexibility programme specifically targeting the hip flexors. At -4, 0, 4 and 8-

weeks, static hip ROM and running kinematic data were collected during 3x2 minute bouts of treadmill running at randomly assigned speeds of 13km/h, 15km/h and 17km/h. Kinematic data were captured using a 13 camera Vicon system. Results Significant improvements in the static hip ROM [F(3, 15)=26.69,  $p=.001$ ,  $\eta^2=0.84$ ] showed that the intervention was successful. However this did not result in significant changes to running kinematics (stride length [F(3, 24)=0.41,  $p=0.75$ ,  $\eta^2=0.49$ ], thigh extension [F(3, 24)=1.49,  $p=0.24$ ,  $\eta^2=0.16$ ], dynamic hip ROM [F(1.47, 11.72)=2.40,  $p=0.14$ ,  $\eta^2=0.23$ ] and pelvic tilt [F(3, 24)=0.68,  $p=0.59$ ,  $\eta^2=0.075$ ]. Discussion It is concluded that whilst the programme was effective at increasing static ROM of motion, these changes were not reflected during running performance. Thus, results suggest that the decreased stride length, thigh extension and pelvic tilt typically exhibited by triathletes may not be solely due to tight hip flexors. Further research is required to investigate what other adaptations may be the cause of the altered running kinematics present in this group and how refining them affects performance. The lack of change in running gait could also be due to participants not knowing how to apply their new ROM nor needing to use it to perform at the velocities used in this study. Further research should be conducted as to the effect of using methods to instruct participants how to accommodate the acquired gains in flexibility. Moreover, this study indicated that participants have sufficient ROM to increase velocity but, unlike experienced runners, are not able to utilize it during slower running. This lends further support to instructing participants in future studies how to use the increased flexibility. References Connick, M.J. and Li, F.-X. (under review). ### **PATIENTS WITH PATELLOFEMORAL PAIN SYNDROME HAVE WEAKNESS OF QUADRICEPS AND HIP EXTERNAL ROTATORS AND REDUCED HAMSTRING AND PSOAS FLEXIBILITY.**

PAPADOPOULOS, K., JONES, J., BARNES, M., THOM, J., NOYES, J.

BANGOR UNIVERSITY

Patients with Patellofemoral Pain Syndrome (PFPS) have weakness of quadriceps and hip external rotators and reduced hamstring and psoas flexibility. 1,2Konstantinos D. Papadopoulos, 2Jane Noyes, 3Moyra Barnes, 1,3Jeremy G. Jones, 1Jeanette M. Thom 1School of Sport Health and Exercise Sciences, Bangor University 2School of Healthcare Sciences, Bangor University 3Betsi Cadwaladr University Health Board, Bangor Introduction PFPS is a common knee problem. The cause and specific treatment are debatable. Muscle weakness and tightness are considered major causes. We set out to investigate which specific muscles are affected. Methods A series of flexibility and isometric strength tests (Humac Norm Isokinetic Dynamometer) used by physiotherapists were performed in 20 patients with PFPS and 20 matched asymptomatic subjects and repeated after a week. Three tests were excluded (unreliable and not valid). The flexibility tests were Ober and Thomas tests (psoas and quadriceps components), and tests for calf and hamstring flexibility. The muscles tested for strength were quadriceps, hip abductors, hip abductors and hip abductors with external rotators (Clam position). Then a fatigue protocol (2 sets of 30 eccentric reps) of hip abduction and external rotation was carried out in the Clam position. Subjects then performed either 3 sets of 20 three stair descents or 3 sets of ten one-leg-squats. The isometric strength tests were then repeated. One week later the protocol was repeated. The first series of tests was discarded because of a learning effect. Independent t-Tests, paired t-Tests and mixed model ANOVA were applied to the second series. Results The Thomas test (psoas) (18.1%,  $p=0.001$ ) and hamstring flexibility test (18.8%,  $p=0.032$ ) were reduced in PFPS group compared to controls, with no difference in the Ober, calf and Thomas (quads) flexibility tests. Strength reduction was found for quadriceps (19.2%,  $p=0.006$ ), external rotators (28.2%,  $p=0.004$ ), hip abductors/external rotators (from clam test position) (42.6%  $p=0.001$ ) in PFPS subjects, while there was no difference in hip abductor in extension strength. The clam fatigue protocol showed more rapid and more severe fatigability in PFPS group with a 20% drop in eccentric torque ( $p<0.000$ ). After the two functional tasks, PFPS group showed reduced isometric strength in hip abductors (7.2%,  $p=0.037$ ) and quadriceps (11.3%,  $p=0.048$ ) whereas only quadriceps strength (11.7%,  $p=0.002$ ) was reduced in controls. Discussion PFPS patients have significant weakness of quadriceps and external hip rotators. Weakness of hip abduction only became apparent on fatigue testing. Flexibility of psoas and hamstrings were lower. This suggests physiotherapy should be aimed at strengthening quadriceps and external rotators, increasing flexibility of psoas and hamstrings and that the Clam test is useful to demonstrate external rotator weakness and as a therapeutic exercise. Ober test did not differentiate between the two groups.

### **LOAD APPLICATION DISTRIBUTION BETWEEN THE RIGHT AND LEFT HAND DURING CLIMBING DEPENDS ON CLIMBING ABILITY AND PRE-EXHAUSTION LEVEL: ASYMMETRY OF LOAD APPLICATION AS PREDICTOR FOR OVERUSE AND INJURY?**

DONATH, L., ROESNER, K., PUTA, C., GABRIEL, H.H.W.

INSTITUTE OF EXERCISE AND HEALTH SCIENCES, UNIVERSITY OF BASEL, BIRSSTRASSE 320B, CH

Background: The Need for systematic information on performance structure is also increasing in sport climbing. To date, cross-sectional studies on break-exertion ratios (BER) and left-right load application time and distribution of the upper extremity related to climbing ability and pre-exhausting level are lacking. Thus, the present study was conducted to evaluate symmetry of load application between right and left hand in different climbing ability groups and in different pre-exhausting conditions. This might be of even greater importance regarding high prevalent overuse and injuries of the fingers (Backe et al., 2009). Methods: 28 sport climbers (Age:  $29\pm 8$  Years; BMI:  $22\pm 2$  kg m<sup>-2</sup>; years of climbing:  $10\pm 6$  years; Ability:  $23\pm 5$  Ewbanks points (australian difficulty scale); weekly climbing frequency:  $2\pm 1$ ) were either distributed in a recreational ( $<23$  Ewbanks,  $n=14$ ) or ambitious ( $>23$  Ewbanks,  $n=14$ ) group. Then, in a randomized order, a pre-exhausted and non-pre-exhausted group has been built. The 12m testing-rout has been set in an axis-symmetric shape. Capillary blood lactate concentration and perceived exertion level (Borg-scale) has been recorded immediately at the end of one climbing attempt. Contact time for load application has been recorded by video analysis separately for the left and right hand. Additionally, symmetry of load application time has been calculated. Results: Wilcoxon signed ranks test revealed significant differences between load application time between left ( $47\pm 4\%$ ) and right ( $53\pm 4\%$ ) hand. The lower the climbing ability and the higher the pre-exhaustion level (lactate accumulation) the more asymmetric load application shifts to the handedness site has been observed. The analysis of variances did not revealed a group effect concerning lactate and heart rate kinetic for recreational as well as ambitious climbers. In this regard, Differences merely occur between the pre- and non-pre exhausted group. Conclusion: The load application time for the handedness hand (right) prevails significantly. This dominance interacts with climbing ability and pre-exhaustion level (lactate accumulation). Further longitudinal studies should investigate, whether asymmetric load application time potentially predicts overuse and climbing injuries. References:

## **ELECTROMYOGRAPHIC AND MECHANICAL RESPONSES TO A SPINALLY INDUCED BALANCE PERTURBATION OF THE PLANTAR FLEXORS**

CATTAGNI, T.

UNIVERSITÉ DE BOURGOGNE

Electromyographic and mechanical responses to a spinally induced balance perturbation of the plantar flexors Cattagni, T., Scaglioni, G., Martin, A. INSERM U887 Motricite Plasticite, University of Burgundy, France Introduction Dynamic posturography associated with electromyography (EMG) recording of lower limb was traditionally used to study muscular and biomechanical reaction to an unpredictable postural perturbation in standing position (De Freitas et al. 2010). However, the methodologies proposed in the literature generally employ exogenic postural disturbance which does not allow perturbing subjects according to their relative abilities. This study, therefore aimed, to establish a method for which the balance disturbance is endogenic and its intensity is related to the physiological capacity of each subject. Methods The soleus H-reflex was used as the source of spinal balance perturbation. Experiments were performed on ten healthy males (age 24.4, SD 2.3 yr) which were perturbed in their standing position by bilaterally applying an electrical stimulation to the tibial nerve. Four different intensities were used. They were the intensities that allowed us to evoke: i) 50% of maximal H-reflex (Hmax) in the ascending phase, ii) Hmax; iii) 50% of the Hmax in the descending phase and; iv) the maximal M-wave. The EMG response of the soleus (SOL), medial gastrocnemius, lateral gastrocnemius and tibialis anterior were recorded simultaneously with the center of pressure (CoP) displacements. A total EMG response to the postural perturbation was calculated as the sum of the peak to peak amplitudes of the H reflex + the M wave of each muscle. The corresponding mechanical perturbation was quantified as the peak to peak amplitude of the CoP displacement in the anteroposterior direction. Results A linear relationship was found between the peak to peak amplitudes of CoP displacements and the amplitudes of the corresponding total EMG responses. ( $R^2=0.83$ ,  $P<0.05$ ). Discussion These results showed that there is a direct link between the endogenic perturbation (i.e. EMG input onto the neuromuscular system) and the postural response. This methodology enables us to perturb the equilibrium of subjects according to their relative ability and thus to determine if the strategy adopted by each individual to re-equilibrate is in accordance with their maximal neuromuscular capabilities. ## **A WIDE NUMBER OF TRIALS ARE REQUIRED TO ACHIEVE ACCEPTABLE RELIABILITY FOR MEASUREMENT PATELLAR TENDON ELONGATION IN VIVO**

SCHULZE, F., MERSMANN, F., BOHM, S., ARAMPATZIS, A.

HUMBOLDT-UNIVERSITY OF BERLIN

1. Introduction This study examined the reproducibility of patellar tendon elongation measurements during isometric knee extension contractions (MVC) using brightness-mode ultrasonography (BMU). We hypothesized that the measurement of the patellar tendon elongation during only one maximal voluntary isometric knee extension contraction would not provide reliable results and that a wide number of trials are required to achieve acceptable reliability. 2. Methods Ten participants performed ten isometric knee extension contractions in two separate days (5 trials on each day). Using a modified knee brace, the ultrasound probe was firmly adjusted in the sagittal plane overlying the patellar tendon. The registered ultrasound images were analyzed by three different but equally trained observers. The reproducibility has been checked by the calculation within-day, between-day, overall and between-observer of the coefficient of multiple correlations (wCMC, bCMC, oCMC, boCMC) (Gronney et al., 1997). The Spearman-Brown prophecy formula at 50% and 100% of the MVC has been used to estimate the required trials to achieve the desired reliability. 3. Results The wCMC, bCMC and oCMC were in average  $0.82 \pm 0.07$ ,  $0.80 \pm 0.18$  and  $0.77 \pm 0.96$  respectively. The mean  $\pm$ SD values of the between-observer CMCs (boCMCs) were for the first day  $0.84 \pm 0.19$  and for the second day  $0.84 \pm 0.14$ . The Spearman-Brown prophecy formula showed that five to six trials are needed to achieve an excellent reliability of 0.95. 4. Discussion High reliability is a fundamental component for comparisons of patellar tendon stiffness values between different groups as well as for the monitoring of patellar tendon adaptation after exercise interventions. Our findings indicated a rather moderate reproducibility of patellar tendon elongation measurements. The present study demonstrates that the examination of the patellar tendon elongation during maximal voluntary knee extension contractions from only one trial did not ensure reliable results. Therefore, it is crucial to use 5 – 6 trials for the measurement of the patellar tendon elongation to achieve high reliability. Further, the results revealed an independency of the measurements from days and observers, which allows comparisons of reported values between different research groups. A basic experience of the observer by digitizing ultrasound images of the patellar tendon is enough to achieve acceptable results on tendon elongation. 5. References Gronney, E., Meglan, D., Johnson, M., Cahalan, T., & An, K. N. (1997). *Gait & Posture*, 6(2), 147-162.

## **RELATIONSHIP BETWEEN NERVE CONDUCTION VELOCITY AND SIZE OF ULNAR NERVE FASCICLES IN HUMANS**

NOBUE, A., ITO, A., ISHIKAWA, M.

OSAKA UNIVERSITY OF HEALTH AND SPORT SCIENCES

Introduction It has been reported in animal studies that nerve conduction velocity (NCV) increases with axonal diameter (Waxman, 1980). In human studies, changes in NCV with age (Norris et al., 1953) and differences of NCV between dominant and non-dominant arms (Hatta et al., 1995) have been observed by applying electrical stimulus to the ulnar nerve. These changes of NCV suggest plasticity of the axonal diameter of nerves. However, it is not clear how humans can increase the axonal diameter of nerves and thereby increase NCV. This is because little attention has been given to the direct measurement of the size of human nerves. Recent developments in ultrasonography have made it possible to scan human nerve fascicles directly. The purpose of this study was to measure directly the cross-sectional area of human ulnar nerve fascicles (CSA) and to examine the relationship between the NCV of the ulnar nerve and the CSA in humans. Methods 10 badminton players with bilaterally different arm size volunteered as subject. Electric stimuli were applied to both arms over the two separate points of the ulnar nerve. The action potential evoked in the muscles of the hypothenar eminence by applying electrical stimulus to the ulnar nerve and the latency of response (the time between stimulation and the onset of the action potential of the muscle) were measured. The NCVs of the nerves in both arm segments were calculated as the distances between the two stimulating electrodes divided by the differences in their latencies of response. CSAs were measured using a high-frequency ultrasound probe (frequency: 18 MHz; image resolution: 0.08 mm). Five CSAs were measured from a point 3 cm in a distal direction from the medial

epicondyle of the humerus to the point 3 cm in a proximal direction from the ulnar head at equal intervals. The five CSA images were analyzed and averaged. The forearm circumferences of both arms were measured using a measuring tape. Results/Discussion NCV, CSA and maximum forearm circumference (MFC) were significantly greater in the dominant limbs ( $53.8 \pm 4.33$  m/sec,  $6.2 \pm 0.9$  mm<sup>2</sup> and  $24.1 \pm 1.8$  cm, respectively) than in the non-dominant limbs ( $50.1 \pm 3.86$  m/sec,  $5.5 \pm 0.6$  mm<sup>2</sup> and  $22.4 \pm 1.9$  cm). These results agree with previous studies (Hatta et al., 1995). However, there was no significant relationship between NCV and CSA. CSA correlated positively ( $r=0.75$ ) with MFC. This result was not consistent with the results of previous animal studies (Waxman, 1980). The results of this study suggest that CSA may increase in proportion to forearm circumference but the difference of NCV cannot be attributed to the size of CSA. References Norris A H. et al. (1953). J Appl Physiol, 5, 589-593 Waxman S G. (1980). Muscle Nerve, 3, 141-191 Hatta A. et al. (1995). Adv Exec Sports Physiol, 2, 177-184

### MUSCLE-TENDON UNIT STIFFNESS DOES NOT INDEPENDENTLY INFLUENCE VOLUNTARY EXPLOSIVE STRENGTH

HANNAH, R.1,2, MINSHULL, C.1, BUCKTHORPE, M.W.2, FOLLAND, J.P.2

1: NOTTINGHAM TRENT UNIVERSITY; 2: LOUGHBOROUGH UNIVERSITY

**INTRODUCTION** Explosive strength, the ability to rapidly exert muscular force, is considered a key determinant of performance during fast and forceful muscle contractions. Muscle-tendon unit (MTU) stiffness may influence explosive strength [1], but its relationship with force production during explosive voluntary and involuntary contractions remains unclear. Any relationship of MTU stiffness with explosive strength may be because both are related to maximum strength (maximum voluntary force, MVF), rather than being independently related. **PURPOSE** To assess the relationship of MTU stiffness with voluntary and involuntary explosive strength of the knee extensors in absolute and relative (to MVF) terms. **METHODS** Following a familiarisation session 34 healthy untrained participants (17 males, 17 females; 19-28 yrs) performed a series of voluntary and involuntary [supra-maximal octets (8 pulses at 300Hz) electrically evoked via the femoral nerve] explosive isometric contractions. MVF was also assessed. Force was measured with a strain gauge perpendicular to the tibia at a knee joint angle of 85°. Force during the explosive contractions was measured at 50 ms intervals after force onset. Maximum rate of force development (MRFD) was measured as the peak slope over 5 ms. Force and MRFD were reported in absolute and relative terms (%MVF). Ultrasonic images of the VL were recorded at rest and during ramped contractions to assess MTU stiffness, which was expressed in absolute (N.mm) and relative (to MVF and resting tendon-aponeurosis length) terms. Stepwise multiple linear regressions assessed the relationship of MTU stiffness with force and MRFD. **RESULTS** Males had a greater MVF, absolute voluntary and involuntary force and MRFD; however, males and females exhibited equivalent relative voluntary and involuntary force and MRFD, and so their data were pooled. Bivariate correlations between absolute MTU stiffness and absolute voluntary ( $0.39 \leq R \leq 0.40$ ) and involuntary MRFD ( $0.47 \leq R \leq 0.71$ ) suggested that stiffness may influence explosive strength. However, regression analysis including MVF as an additional predictor variable showed absolute MTU stiffness did not contribute to the explained variance in absolute voluntary force at any time point, or MRFD. Similarly, relative voluntary force and MRFD were unrelated to relative MTU stiffness. However, MTU stiffness accounted for 4%, 8% and 11% of the variance in absolute involuntary force at 50 ms, absolute and relative involuntary MRFD, respectively. **CONCLUSION** Once maximum strength was considered, MTU stiffness had no independent relationship with voluntary explosive strength, and a weak association with involuntary explosive strength. **REFERENCES** [1] Bojsen-Moller et al. (2005) J Appl Phys, 99, 986-994

### THE INFLUENCE OF PLAYING SURFACE AND CLEAT DESIGN ON ACL-INJURY INCIDENCE: A PROSPECTIVE STUDY.

VERSCHUEREN, J., AERTS, I., BLOCK, S., MEEUSEN, R.

VRIJE UNIVERSITEIT BRUSSEL

**Introduction** Soccer is a very popular sport with a high injury incidence in men (10 – 35 injuries/1000 match exposure hours) and women (2– 24 injuries/1000 match exposure hours) (Hawkins et al., 1999) with the ankle (17,0 – 26,0%) and the knee (17,0 – 23,0%) being the most frequently injured and 20% of the knee injuries being ACL injuries (Dvorak & Junge, 2000). No consensus exists about the effect of the cleat design, a specific form and positioning of rubber studs, and the playing surface on the ACL-injury incidence. The aim of this study was thus to determine the incidence of ACL injuries in soccer and to investigate the influence of the playing surface and the cleat design on the ACL-injury incidence. **Methods** A 1 year prospective study design was used during the 2007 – 2008 soccer season. 25 female (n=277) and 19 male soccer teams (n=315) participated in the study. Lower limb injuries and mechanisms were monitored with a validated self-reporting questionnaire (Knaepen et al., 2007). Chi<sup>2</sup> and t-tests were performed to identify significant differences ( $p=0.05$ ) and correlations were analyzed with Kendall's Tau – b tests and ICC. **Results** We registered 344 lower limb injuries in 592 players. During the season 39,1% male soccer players got injured, compared to 37,9% females ( $p<0.05$ ). The amount of non-contact ACL injuries was markedly higher ( $p<0.05$ ) in female players (15,4%) compared to male players (9,8%). Eighty percent of all ACL-injuries occurred wearing shoes with the cleat design ( $p<0.05$ ). As for the playing surface, logical regression analysis showed that a soft and muddy surface was a significant predictor. **Discussion** Our study confirmed the higher ACL-injury risk for women and the non-contact injury mechanism. Earlier research showed that the cleat edge design increases the risk of an ACL-injury in American football (Lambson et al., 1996), but this was not confirmed in a more recent study in soccer (Gehring et al., 2007). A biomechanical study concluded that a higher shoe-surface interface is a possible risk factor for non-contact ACL-injuries (Drakos et al., 2010). This is reflected in our study, with the playing surface being a significant predictor for ACL-injuries, and the significant higher amount of ACL-injuries in players wearing the cleat design. **References** Drakos M, Hillstrom H, Voos J, Miller A. **MECHANICAL FACTORS OF ACHILLES TENDON RUPTURE IN KENDO** Miyamoto, R.1, Ishige, Y.2, Taniguchi, Y.2, Ohoya, M.2 1: KAMEDA INSTITUTE OF SPORTS SCIENCES AND MEDICINE (Chiba, Japan), 2: International Budo University (Chiba, Japan) **Introduction** The Achilles tendon rupture often occurs in sports activities. In Kendo also, the Achilles tendon rupture is the most popular trauma, but the pattern of rupture is distinguishing characteristics. First, the injured leg is almost left side. (Nango, 2007) Second, the movement patterns which lead to rupture concentrate on the stepping forward movement just after backward movement and just after 180 degrees turn. (Matui et al,

1996) There are so many studies regarding the Achilles tendon rupture in Kendo. Most of those studies are dealing with prevention and its causes. But there are few studies which are examined from the mechanical point of view. So in this study we conducted the computer simulation of stepping forward movement in Kendo and quantitate the loads of Achilles tendon. Methods The research subjects were five male students who were the members of the University's kendo club. (age:  $19.5 \pm 1.0$  years, height:  $170.9 \pm 2.8$ cm, weight  $66.8 \pm 10.4$ kg) Each subject performed seven trials of stepping forward movements just after backwards which is typical motion in Kendo. 33 landmarks on the subject's body were captured through motion capture system (Eva-RT, Motion Analysis, USA) during those movements. At the same time the ground reaction force and EMG data were measured. All data were integrated into musculoskeletal model (nMotion muscular, NAC, JAPAN) in order to calculate the tension and length of the Achilles tendon. Results The average tension of the left side Achilles tendon at peak value was 2380N. The moment at which the left Achilles tendon force reach the maximum value corresponded with the instant of which the left leg struggle to stay on its feet at the latter part of stepping backward movement. Discussion Before it is considered that the most dangerous moment was just around the stepping forward movement. (Sato et al 2000.) However we speculated from our results that the moment of Achilles tendon rupture happened when the subject tried to stay on his left feet at the latter part of stepping backward movement. At this moment, the tension of Achilles tendon was two times larger than that of during stepping forward movement. Also the muscle activity of left gastrocnemius was active and Achilles tendon was elongated. This meant eccentric action of Achilles tendon. References Nanogo A, (2007). ## FUNCTIONAL OUTCOME AND ACTIVITY LEVEL AFTER TOTAL KNEE ARTHROPLASTY

MAU-MOELLER, A., BEHRENS, M., BADER, R., BRUHN, S.

UNIVERSITY OF ROSTOCK

Introduction There is growing evidence that total knee arthroplasty (TKA) reduces pain and improves quality of life [2]. But in contrast to healthy people of the same age, deficiencies in function have been demonstrated [3]. The investigation of functional outcome and activity level makes a contribution to the understanding of the mechanisms of motor deficits before and after TKA. This is of importance for rehabilitation and prevention of further injuries due to falls. This study is currently in progress. Data of seven patients have been analyzed so far. Further results including a larger number of patients will be presented at the congress. Methods Seven patients with primary osteoarthritis (OA) and seven healthy age- and gender-matched controls participated. The OA group was tested one day before (pre) and at ten days (post1) and three months (post2) after TKA. The tests included (1) maximum voluntary contraction (MVC) of the leg muscles, (2) static postural control during bipedal stance under two conditions (open and closed eyes), (3) regional and whole body fat mass and lean mass (DEXA), (4) physical activity. Results Three month after surgery MVC was increased in the surgically treated and contralateral leg. In comparison with controls, patients' MVC of the operated leg was significantly lower before and after TKA. Area and velocity of the centre of pressure (COP) for each condition were significantly increased from pre- to post1-test in patients. Between post1- and post2-test patients' results differ in terms of postural control under the two conditions. COP parameters were significantly decreased with eyes open, whereas no differences were shown with closed eyes. In contrast to the controls, patients showed higher values of COP before and after TKA and a significantly lower physical activity level. Discussion The functional deficits and reduced activity level before and after surgery might be predominantly due to a destruction of articular tissues and pain. TKA led to an improvement of MVC, but muscle strength was not equivalent to that of people without OA. Disuse atrophy and failure of volitional activation probably induced by arthrogenic inhibition have been primarily suggested as causes of reduced muscle strength before and after TKA [3]. Patients still had profound impairment of balance under condition of visual deprivation three month after TKA. The high reliance on visual information suggests impaired sensory feedback from the lower limb and a shifting to a more visually dominated control strategy [4]. References 1. Levinger P, et al. ## EFFECTS OF EXERCISE THERAPY BASED ON REINFORCEMENT OF PROPRIOCEPTIVE SYSTEM ON THE TREATMENT OF ADOLESCENT IDIOPATHIC SCOLIOSIS AND BALANCE CONTROL

ASLANZADE, F.1, ASLANZADE, A.2, FARAHPOUR, N.3, KOSAR, S.N.4

1:MIDDLE EAST TECHNICAL UNIVERSITY (ANKARA, TURKEY), 2: BASU (HAMEDAN, IRAN) 3: AIU (TEHRAN, IRAN) 4: HU (ANKARA, TURKEY)

Introduction Adolescent idiopathic scoliosis (AIS), a three-dimensional deformity of the spine, is the most common form of spinal deformities affecting girls aged 10-16 years. Due to the several sensory and motor impairments AIS patients exhibit a weak postural control and balance dysfunction (1). On the other hand, there are few studies investigating the effectiveness of exercise therapy based on reinforcement of proprioceptive system (RPS) in AIS treatment and control of balance (2). Therefore, the purpose of this study was twofold: the first one was to evaluate the ability of AIS patients to cope with sudden sensory deprivation and transform their sensory perception into appropriate motor commands, and the second one was to determine the effectiveness of a 6 month of exercise therapy based on RPS on scoliosis curve and balance control. Methods Twelve premenarchal AIS girls with a Cobb angle range of 10 to 20 degrees (average  $12.8 \pm 2.3$  degree) and fifteen healthy girls (C) participated in the experiment. Cobb angle and standing balance were measured before and after 6 months of exercise therapy based on RPS (90min/day, 3 days/week). Standing balance was measured on a Biodex force platform in different perturbed conditions (eyes closed and/or destabilizing surface). Analyses of variance (ANOVA) with repeated measures were used to analyze the data. Results Perturbation of visual information in both stable and destabilizing surface increased the body sway of scoliosis patients compared to control condition ( $p < 0.01$ ). Balance control of scoliosis patients was weaker than healthy subjects which improved significantly after 6 months of exercise treatment in all conditions ( $p < 0.05$ ). Exercise therapy based on RPS decreased Cobb angle significantly ( $p < 0.05$ ). Cobb angle decreased in 92.5% of patients by 3.5 degree on average. Discussion This research showed that AIS patients exhibit significant impairment in proprioceptive system, and compared to healthy subjects, they rely more on visual inputs rather than proprioceptive information to regulate balance. Exercise therapy based on RPS was effective in improving balance control, and reducing the magnitude of Cobb angle. In conclusion, exercise therapy based on RPS is recommended in the treatment of AIS to reduce the progression of spinal deformity and improve balance control in patients with minor spinal deformity. **THE INFLUENCE OF RANGE OF MOTION IN STRENGTH GAINS AND MUSCLE HYPERTROPHY OF ELBOW FLEXORS**

REIS GAYA, A., RADAELLI, R., GOMES, N., BOTTON, C., PINTO, R.

SCHOOL OF PHYSICAL EDUCATION. UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL

Among the variables of strength training that have influence under strength gains and muscle hypertrophy, the range of motion in which the exercise is realized, seem have a important influence in adaptations. Therefore, of the purpose of present study, was compare the effect of ten weeks of strength training with Full (FROM) and partial (PROM) range of motion of elbow flexion in one maximal repetition (1RM) value and muscle thickness (MT), in three locals of elbow flexors distal (EF1), middle (EF2) and proximal (EF3). Forty male young subjects without training experience were divided in three groups: FROM (n=15; 21.7  $\pm$  3.7 years; 74.9  $\pm$  11.0Kg; 1.74  $\pm$  0.3cm), PROM (n=15; 21.7  $\pm$  3.3 years; 73  $\pm$  8.9Kg; 180  $\pm$  0.3cm), and control (n=10; 25.4  $\pm$  2.9years; 73  $\pm$  5.7kg; 179  $\pm$  0.9cm). The training was realized during ten weeks of bilateral mode utilizing a curling bar. The FROM group trained with range of 0° to 130° of elbow flexion (0° full elbow extension), and PROM group trained with range of 50° to 100° of elbow flexion (0° full elbow extension). The groups trained at week 1 and 2 with two sets with 20 repetitions, at week 3 and 4 with three sets of 15 repetitions, at week 5 and 6 with 3 sets of 12 repetitions, at 7 and 8 with 3 sets of 10 repetitions and 9 and 10 weeks with four sets of eight repetitions. The 1RM and muscle thickness of elbow flexors was assess at three locals, distal, middle and proximal (EF1, EF2 and EF3, respectively), were assessed pre, middle (week 5) and post training (10 week). Kruskal Wallis test and post hoc Dunnet C was utilized to analyze the changes in 1RM and MT among groups and two related sample to analyze within groups. The FROM and PROM showed significant increase (p<0.001) in the 1RM value after five weeks (16.2  $\pm$  9.7% and 8.3  $\pm$  4.5%, respectively) and ten weeks (25.7  $\pm$  9.6% and 16  $\pm$  6.7%, respectively), however the FROM group demonstrated significant increases (p<0.001) than PROM group after five and ten weeks. Both groups, FROM and PROM, showed significant increase (p<0.001) in the MT at all locals (EF1, EF2 and EF3), after five and ten weeks. However, the FROM group demonstrated significant increase (p< 0.001) than PROM group in all locals MT (EF1,EF2 and EF3) only after ten weeks. The results of present study demonstrated superiority of the training realized with full range of motion in gains of strength and muscle hypertrophy, moreover this results demonstrated the range of motion in which the exercise is realized have important influence in adaptations.

**Poster presentations****PP-BN04 Motor Learning 1****INTERSEGMENTAL DYNAMICS SURPASS AUGMENTED VISUAL FEEDBACK IN LEARNING COMPLEX RHYTHMIC MULTI-JOINT COORDINATION**

STOSIC, J., CARROLL, T.J., DE RUGY, A.

THE UNIVERSITY OF QUEENSLAND

In rhythmic movements, some patterns of coordination are intrinsically stable and require little or no practice to be performed (typically 0 and 180 degrees relative phase, RP), while other require substantial practice. The factors that influence learning of difficult coordination patterns depend on the context, such that there is no general agreement about the best approaches to facilitate learning. The present study compares three different methods to assist learning of a difficult 90 deg out of phase coordination between rhythmic flexion-extension (FE) and supination-pronation (SP) movements at the elbow: (i) practice with standard visual feedback (SVF), (ii) practice with augmented visual feedback (AVF), and (iii) practice with a favourable context of intersegmental dynamics in the form of interaction torques (IT), under SVF. Twelve subjects were randomly assigned to 1 of these 3 practice groups (SVF, AVF and IT). SVF consisted of one visual cursor per each of 2 axis of motion (one for FE and one for SP). AVF consisted of single visual cursor encapsulating both FE and SP movements (i.e., lissajou plot). Finally, IT was applied by a motorized device on SP axis as a function of FE movement in order to favour the intended 90 deg relationship. Performance was assessed for all three groups with eyes open (EO, SVF) and closed (EC) in pre- and post-learning tests. Averaged RP for all groups in post-test was approximately 45-55 deg. During learning with AVF, subjects were able to produce close to 80 deg RP, but in post-test (EO assessed with SVF), RP dropped and coordination stability decreased (p=0.04). On the other hand, other groups had similar RP during learning and post-test, probably because the same feedback (SVF) was maintained throughout. The IT group (with favourable dynamics) and AVF group (with visual help) had higher coordination stability than the SVF group during the second half of learning (p<0.01). In post-test, whereas coordination stability dropped in the AVF group, it remained high and similar to the last training trials, for the IT group. Consequently, AVF can assist in achieving the coordination task, but not to retain it once the visual help is removed (i.e. performance dropped with the SVF in the post-test). In marked contrast, coordination stability was not affected when the favourable context of intersegmental dynamics was removed in the post-test of the IT group. This suggests that IT provides a better approach to learn a 90 deg RP relationship under standard visual feedback.

**OCULO-MANUAL PURSUIT DURING TRANSIENT OCCLUSION OF EXTERNALLY GENERATED TARGET MOTION**

O'DONNELL, D., HANSEN, S., BENNETT, S.

LIVERPOOL JOHN MOORES

OCULO-MANUAL PURSUIT DURING TRANSIENT OCCLUSION OF EXTERNALLY GENERATED TARGET MOTION O'Donnell, D.I., Hansen, S.2, Bennett, S.1 1: LJMU (United Kingdom), 2: Nipissing University (Canada) INTRODUCTION When tracking an externally-generated moving target that is suddenly occluded, there is decay in smooth pursuit followed by an anticipatory recovery (Bennett and Barnes, 2003). Presenting trials in blocked order results in less decay and a predictive recovery, thus demonstrating volitional control. It has been suggested that smooth pursuit is also facilitated when the occluded target trajectory is internally generated (Gauthier and Hofferer, 1976). However, this was based on a comparison to an eye alone condition where participants were unable to exhibit any smooth pursuit. To better understand the contribution made by sensorimotor signals to the oculomotor system, the current study examined ocular and oculo-manual pursuit during the transient occlusion of externally-generated target motion. METHODS Participants tracked a target moving horizontally with velocity of 10, 15, 20deg/s. The target was initially visible for 600ms, then occluded for a 600, 800, 1000ms inter-stimulus interval (ISI), before reappearing for 400ms. Participants were instructed to pursue the target with the eyes alone (ocular) or eyes and hand (oculo-manual) during both the visible and occluded portions of the trajectory. During oculo-manual conditions, participants were tasked with keeping the moving target within a spherical hand cursor. RESULTS The decay of smooth pursuit during occlusion was attenuated during oculo-manual compared to ocular tracking (F(1,9)=5.64; p<0.05). At the moment of target reappearance, there was a

significant interaction between tracking condition and target velocity ( $F(2,18)=12.33$ ;  $p<0.05$ ). Oculo-manual tracking produced better scaling of smooth pursuit at the moment of reappearance for each level of target velocity ( $p<0.05$ ). This improvement in smooth pursuit during occlusion was reflected in a concomitant increase in smooth eye displacement ( $F(2,18)=7.30$ ;  $p<0.05$ ), and a reciprocal decrease in saccadic eye displacement ( $F(2,18)=10.40$ ;  $p<0.05$ ). **DISCUSSION** Using a paradigm in which target motion was externally generated, it was found that smooth pursuit during occlusion was facilitated by the contribution from sensorimotor signals available during oculo-manual pursuit (cf. Gauthier and Hofferer, 1976). Importantly, however, this facilitation was unable to fully offset the loss of input from visual feedback. As shown previously, hand and eye velocity showed elements of independence, which is consistent with smooth pursuit facilitation by adaptation of an internal gain mechanism (Lazzari, Vercher, Buizza, 1997). **REFERENCES** Bennett S, Barnes, GR. ## STABILITY AND VARIATION IN MOTOR FUNCTION

SEGBERG, U.

UNIVERSITY OF AGDER

**STABILITY AND VARIATION IN MOTOR FUNCTION- A 6 YEAR LONGITUDINAL STUDY OF MOTOR FUNCTION IN NORWEGIAN CHILDREN.** Segberg, U., Hoigaard, R. Agder University College, Kristiansand, Norway **Introduction** There is an increasing concern about lower degree of physical activity among young children, especially related to physical fitness (Sallis et al., 2000) and psychological well-being (Biddle, S. and N. Mutrie, 2007). The data presented here are part of a larger longitudinal study that evaluates the relation between motor performance, self concept, social competency and contextual conditions. The data presented here highlights only motor function. The purpose is to monitor the stability and variation of motor function from grade 1 to 7. **Methods** At baseline, in grade 1, 96 children are tested with the German KTK – Körper Koordinationstest für Kinder. (Body Coordination Test for Children) (Kiphard & Schilling, 1974). In grade 7, at the final test, 77 children still are in the sample. **Results** There is a significant correlation between MQ in grade 1 and 7 ( $r(\text{pearson}) = 0.63$ ,  $p(< 0.001)$ ). The variance between the best and the weakest MQ increases from grade 1 to grade 7. The children are grouped in three levels (weak; average; strong) regarding to their MQ. The majority of the children 54 of 77 (~ 70%) stayed at the same level in grade 1 and 7. Among the children with weak motor performance ( $MQ < 80$ ) in grade 1, approx. 60% are still in the same group in grade 7. 68% of the children with best motor skills in grade 7 have been in the strong group at grade 1. A similar tendency has been observed for the average group (~70%). The strong group ( $MQ > 100$ ) contains more children in grade 7 than in grade 1. **Discussion** There is a great extent of stability in motor function from grade 1 to grade 7. The variance of motor function increases from grade 1 to grade 7. These findings support demands that motor-intervention programs have to start as early as possible, preferably before primary school. **References** Biddle, S. and N. ## EFFECT OF EXERCISE-INDUCED FATIGUE ON POSTURAL CONTROL OF THE KNEE

HASSANLOUEI, H.1, ARENDT-NIELSEN, L.1, KERSTING, U.G.1, FALLA, D.1,2

1CENTRE FOR SENSORY-MOTOR INTERACTION, DEPARTMENT OF HEALTH SCIENCE AND TECHNOLOGY, FACULTY OF MEDICINE, AALBORG UNIVERSITY, DENMARK. 2 UNIVERSITY MEDICAL CENTER GÖTTINGEN, GERMANY

**Introduction:** Muscle fatigue is an inevitable part of high intensity exercise and is associated with reduced power output and work capacity of the skeletal muscle. Fatigue-induced impairments are believed to be a potential cause of increased injury rates during the latter stages of athletic competition particularly during sudden deceleration (Yu & Camner, 2007). **Methods:** Fatigue was induced using dynamic exercise which was performed on a bicycle ergometer. The Subject's maximal heart rate (HR) was calculated using the Carvenon equation. After the warm up the workload was increased until each subject reached 80 - 90% of their maximal heart rate and, thereafter, was kept constant until exhaustion. Surface electromyographic (EMG) signals were recorded from 10 healthy men from the knee extensor muscles (vastus medialis, rectus femoris, and vastus lateralis) and knee flexor muscles (the medial and lateral heads of the hamstring) of the right leg during full body perturbations at baseline and immediately following the high intensity exercise protocol. The platform was set to perform four perturbations: 8 cm forward slide, 8 cm backward slide, 10° posterior tilt, and 10° anterior tilt. Each perturbation was repeated eight times for a total of 32 perturbations. The 32 perturbations were randomized and occurred with random time intervals of 7 - 20 s, so that neither the type nor the time of the perturbation could be predicted by the subjects. Maximal voluntary knee extension force and conduction velocity of the vasti muscles were measured during sustained isometric knee extension contractions before and after the high intensity exercise to confirm the presence of fatigue. **Results:** The maximal voluntary contraction force decreased by 63% immediately after exercise ( $P<0.0001$ ) for knee extension ( $239\pm75.04$ ) and by 66% ( $P<0.0001$ ) for knee flexion ( $75\pm24.32$ ). Moreover muscle fiber conduction velocity recorded from the vasti muscles decreased post exercise compared with the pre exercise condition ( $P<0.05$ ). During the post exercise postural perturbations, the EMG average rectified value (ARV) was significantly lower than the pre-fatigue condition for both the knee extensor (baseline:  $19.73\pm25.48\mu V$ , post exercise:  $16.29\pm19.42\mu V$ ) and flexor (baseline:  $24.39\pm20.92\mu V$ , post exercise:  $13.88\pm11.06\mu V$ ) muscles (both  $P<0.05$ ). **Discussion:** fatigue has been demonstrated to have an adverse effect on neuromuscular control (M. P. Miles et. al, 1997). One way of quantifying an aspect of neuromuscular control is through measures of postural control. Muscle fatigue induces a reduction in the activation of both the quadriceps and hamstring muscles in response to rapid destabilizing perturbations potentially reducing the stability around the knee during such a destabilizing event. **References** Yu, B., & Garrett, W. ## COMPARISON OF LOVER LEG MUSCLE ACTIVATION DURING FREELY CHOSEN AND PREDEFINED STEP LENGTH

DOLENEC, A., STIRN, I., STROJNIK, V.

UNIVERSITY OF LJUBLJANA, FACULTY OF SPORT

**Introduction** When running with predetermined foot impact positions the co-activation of the lower leg muscles is higher with respect to free running due to accuracy demands (Luc et al., 2005). The aim of the study was compare the activation of some lower leg muscles during running with freely chosen step length and predefined step length, both of the same length. **Methods** Seven male (26 yrs; 178 cm; 76 kg) and two female (24 yrs; 169 cm; 62 kg) volunteers participated in this experiment. They ran six times 50 m on tarmac with rest 3 min between the runs. First three runs the subject ran in freely chosen velocity and step length (FSL). The velocity was measured in the last

30 m with photo cells. The next three runs the subject ran in freely chosen velocity but predefined step length (PSL). The step lengths were the same as in previous runs and were marked on the ground so that the subject had to step on the mark while running. Two trials (one of each condition) of similar running velocities were chosen and nine consecutive steps in the last 30 m were analyzed. EMG signals from m. soleus (SOL), m. gastrocnemius medialis (GM), m. tibialis anterior (TA) and m. peroneus (PER) of the right leg were recorded according to the SENIAM recommendations. Contact times (CT) were measured with accelerometer fixed on the heel of the shoe. The EMG signals were divided to pre-activation phase (-100 to 0 ms of pre-contact time), reflex mediated phase (30 to 120 ms of contact time) and entire contact phase (CT). Average EMG amplitude of these phases was analyzed. Descriptive statistics and paired-samples T-test were used to compare two running conditions. Results Freely chosen running velocities ranged from 3.75 to 5.45 m/s. There was no significant difference between mean velocities in each condition. The average contact times were 219 ms ( $\pm$  25 ms) and 216 ms ( $\pm$  25 ms) for FSL and PSL respectively and were not significantly different. We did not find any significant differences in EMG amplitudes between both conditions as well. Discussion We found no differences between FSL and PSL showing that accuracy of foot landing itself did not necessarily change the muscle activation pattern related to joint ankle stabilization. It seems there must be other influences related to accuracy to induce certain degree of variability into the running that provoke adaptation in ankle control during running. References Selen, LPJ, Beek PJ, van Dieën JH. (2005). Biological Cybernetics, 93, 373-381.

## INSIDE THE BRAIN OF EXPERT ICE HOCKEY PLAYERS: AN FMRI STUDY OF GAME INTELLIGENCE

LUNDSTRÖM, P., OLSSON, C.J.

*SURGICAL AND PERIOPERATIVE SCIENCES*

Introduction Success in sports is heavily dependent on the ability to anticipate actions in order to effectively react to situations that may occur during a game. A previous study showed that expert athletes pick up kinematic cues earlier than novices and therefore it was suggested that they have more time to make correct decisions (Aglioti et al., 2008). However, the underlying brain mechanism of such superior behavior is still not well understood. In this study, we examined expert superiority to anticipate outcome of game actions in ice hockey as well as the underlying neuronal mechanisms. Methods We used functional magnetic resonance imaging (fMRI) to measure regional blood flow while presenting videos of a hockey player shooting a puck towards a hockey goal. The videos (a total of 120) where stopped at different time frames with different amount of information provided, creating a paradigm with three different levels of difficulty to decide the fate of a shot. This allowed us to separate the performance between expert hockey players and novices. Results The results showed that expert hockey players were significantly more accurate compared to novices on deciding where the puck would go. The imaging results showed that when expert hockey players observed and anticipated the situation they recruited regions in the motor cortex. Further, when the difficulty increased they also recruited the superior temporal sulcus (STS), a region that previously been associated to social cognition. Novices, on the other hand, recruited visual regions when observing the situations. During the decision, hockey experts again used motor cortex, as well as hippocampus, to correctly anticipate the shot. In comparison, novices used frontal regions of the brain. Discussion These results suggest that the superior performance experts show can be explained by them using different brain structures both when observing game situations as well as when deciding upon the fate of the shots. Novices needed to visually search the situations for clues and then use cognitive resources to solve the task. Experts could instead recruit the motor representation and, thus, use their stored motor skills to know where the puck would go. We conclude that motor expertise and skill to analyze biological motions are necessary to effectively anticipate game actions. References: Aglioti M.S., Cesari P., Romani M. & Urgesi C. (2008). Action anticipation and motor resonance in elite basketball players. Nature Neuroscience. 11, 1109-1116.

## CONFIGURATION OF SPINAL PROJECTIONS OF THE LOWER LIMB MUSCLE MOTONEURONS IN HUMANS

ANDRIYANOVA, E., LANSKAYA, O.

*VELIKIYE LUKI STATE ACADEMY OF PHYSICAL EDUCATION AND SPORTS*

To research motoneuron nets, providing motion at the spinal level, there was made mapping of the lower limb skeletal muscle representation. We used the technique of registration of multisegmental monosynaptic responses (MMRs) (Courtine, S.J. Harkema, Ch.J Dy et al., 2007) which were evoked by percutaneous surface electric spinal cord stimulation at the lower thoracic and lumbosacral levels. These responses are equivalents of the H-reflex. The main idea was to map the spinal projection area defined by the number of points in the interspinal intervals at the T11-T12, T12-L1, L1-L2, L2-L3, L3-L4 levels. The percutaneous surface electric stimulation of these intervals led to registration of the reflex motor responses of the following bilateral limb muscles – m. biceps femoris, m. hamstrings, m. soleus, m. flexor digitorum brevis. The method of selection of the threshold stimulus, for each of the above mentioned points of surface projection of the spinal cord, was applied. The smallest threshold point is supposed always to correspond to the spinal cord level of the greatest density of motoneurons, that innervate the particular lower limb muscle. A group of healthy males (n=18) aged 17-22 was involved into the investigation. It was established that the stimulation of each indicated level was accompanied by registration of the responses of each studied muscle. Nevertheless, the test revealed that the optimal position, to get the responses from all the studied muscles, was T12-L1. It was also confirmed by the highest meanings of MMRs' maximal amplitudes received at that particular level stimulation in comparison with the meanings of MMRs' maximal amplitudes obtained at the stimulation of the other studied levels. Somatotopic mapping of muscle representations in the spinal cord allows to study spinal neural nets adaptation, to meet requirements of athletes' physical loading, and the nets modulation under the influence of pathology factors.

## EFFECT OF ACUTE EXERCISE ON PLASTICITY OF THE HUMAN MOTOR CORTEX

LAVENDER, A.P.1,2, OBATA, H.2, NAKAZAWA, K.1.

*THE UNIVERSITY OF TOKYO*

EFFECT OF ACUTE EXERCISE ON PLASTICITY OF THE HUMAN MOTOR CORTEX Lavender, AP.1,2, Obata, H.2, Nakazawa, K.1. 1: The University of Tokyo (Tokyo, Japan), 2: National Rehabilitation Centre for Persons with Disabilities (Tokorozawa, Japan) Introduction A higher level of physical activity likely leads to improvements in psychomotor abilities (Plunzevic-Gligorska et al. 2010). Investigations have concluded that aerobic exercise can improve scores of cognitive tasks in healthy children (Reed et al. 2010) and older adults (Barella et al. 2010). These studies looked at effects of chronic exercise regimes on cognitive function only. In addition, enhanced neuroplasticity has been shown in highly active individuals compared with sedentary subjects (Cirillo et al. 2009). The effect of acute exercise on plasticity of the motor cortex has not yet been addressed. The present study, therefore, sort to investigate the effect of moderate aerobic exercise of the lower limbs on cortical excitability of a hand muscle (not involved in the exercise) using paired associative stimulation (PAS) which is

commonly used to induce neural plasticity in awake humans. Methods Right handed subjects aged 21 – 40 years attended the laboratory on three occasions separated by at least two days. An intermittent isometric finger abduction PAS protocol of the right first dorsal interosseous muscle (FDI) was conducted during each visit. A magnetic pulse at the hand area of left motor cortex elicited motor evoked potentials (MEP) of 1 mV in FDI preceded by an electrical stimulation of the ulnar nerve at the wrist with an interstimulus interval of 25 ms. PAS consisted of 180 stimulations at 0.2 Hz. MEP were measured before PAS and at five min intervals for 30 min after PAS. Each PAS session was preceded by either 30 min of stationary cycling at 60% age-predicted maximum heart rate ending 30 min or 120 min before or a control condition not preceded by exercise. Results MEP amplitude increased similarly between the control and 120 min conditions, peaking five min post exercise at  $161 \pm 42\%$  and  $152 \pm 36\%$  of the pre-test value respectively. However, MEP following PAS preceded 30 min by the exercise bout increased to  $249 \pm 59\%$  five min after exercise and remained elevated at  $233 \pm 54\%$  30 min later. Discussion These results suggest that moderate aerobic exercise 30 min before PAS modulates synaptic proteins in the motor area which may play a role in exercise-induced brain plasticity. The influence of exercise does not appear to last long as the modulation of MEP was similar for the control and 2 hrs conditions. References Barella LA, Etnier JL, Chang YK. ## RELATIONSHIP BETWEEN MOTOR PERFORMANCE AND BODY MASS INDEX OF SCHOOL PUPILS IN ZURICH

TOMATIS, L., KREBS, A., SIEGENTHALER, J., MÜLLER, R., MURER, K.

ETH ZURICH

Introduction The analysis of correlations between the motor performance and the health of children is an essential basis for the development of effective prevention approaches (Krombholz, 2006). Since in Switzerland reports on children's motor performance are missing (Müller et al., 2007), the Institute of Human Movement Sciences and Sport of the ETH Zurich annually assesses the motor performance of all first-grade pupils in the city of Zurich (start in 2005). The aims are to evaluate the long-term development of first-grade pupils and to link health parameters and motor performance. Methods During gym class, motor tests were performed with 14'521 first grade pupils (mean age  $7.1 \pm 0.4$  years, weight  $25.2 \pm 4.8$  kg and height  $124.2 \pm 5.5$  cm). The tests were chosen from existing test series (KTK, AST 6-11, Eurofit): Lateral Jump (LJ), 20m-Sprint (20m), Standing Long Jump (SLJ), Plate Tapping Test (PT) and Shuttle Run (SR). In addition, age, weight and height were assessed. Overweight and obesity were calculated according to Cole et al. (2007), with an age-adjusted scale. The significance level was set to 0.05. Results About 10 to 14 % of all subjects are overweight (obesity excluded) and 4 to 5 % of them are obese. No trends in body mass index (BMI) were detected in populations tested between 2005 and 2010. BMI poorly correlates with motor performance in first-grade pupils (0.13 LJ, 0.19 20m, 0.23 SLJ, 0.29 SR for boys and 0.13 LJ, 0.15 20m, 0.22 SLJ, 0.28 SR for girls; PT was not significant). However, the group with normal BMI performs significantly better than the overweight group and the overweight group perform significantly better than the obese group in almost all tasks (except for PT). In SR, the obese subjects performed significantly worse than the overweight ones (30 % less for boys, 22 % less for girls) and the ones within a normal weight range (49 % less for boys, 40% less for girls). Discussion Our results show the importance of a long-term assessment: the values of overweight and obese children are quite high but stable over the years. Only a long-term observation would be able to show whether the BMI of children changes. Significant differences in performance rate have been observed between normal weighted, overweight and obese children in specific tests: even if BMI has poor correlation with motor performance due to the large subject variance, the normal weighted group performs better than overweight and obese children. ## REFLEX-FUNCTIONAL EXERCISE FOR THE FIRST YEAR INFANTS

SHKLYARENKO, A., KOVALENKO, T., PASHKOVA, L.

VOLGOGRAD STATE UNIVERSITY

REFLEX-FUNCTIONAL EXERCISE FOR THE FIRST YEAR INFANTS A. SHKLYARENKO, T. KOVALENKO, L. PASHKOVA Volgograd State University Slavenskiy-on-Kuban Pedagogical State Institute, Russia Introduction. It is well known that the first year of a child has its crucial effect on his future life in many respects. It is exactly in this period that many infant body systems should get their correct development. Study methods and management. We performed and tested for seven years a reflex-functional complex of exercise with the use of physical culture devices for newborns and first year children. This training helps to achieve high performance in infants' development and rehabilitation. Research results and their discussion. The physical exercise was treated as an integral movement activation and not as separate muscle group training. Massage in combination with physical exercise proved their effectiveness. When estimating the physical exercise we presume that its mechanism of action is based on the motor-viscerogenic reflex. The motor activity had its major influence. The reflex-functional training that we offer is aimed at this link of regulation by reference of different afferent systems. The movement force, its proper value and direction were used. Furthermore, we sought out the most appropriate biologically approved methods of mobilization of growing organism adaptive, protective and compensatory properties. It is well-known that when doing physical exercise arousal summation in nerve centers accrues. It must be emphasized that the exercise establishes with babies not only physical but also psycho-emotional contact. When doing the reflex-functional complex of exercise the following regulations and rules were observed: - establish a contact with a baby; - start a massage or gymnastics with simple exercises and manipulations: gradually complicate and introduce new elements; - avoid strong grasps, pushes or any compression of infant's tissue and joints; - all the procedures and movements must be executed carefully, accurately and professionally; - do not use any massage cream or baby talk. Conclusion: Analyzing and comprehending all the factual material we can presume that the therapeutic reflex-functional complex of exercise with the use of physical culture devices contributes to the optimal development of all body systems of newborns and first year children due to the adaptive and functional modifications such as urgent adaptation to one-time loads and long-term adaption to systematic loads.

## THE DIFFERENCES IN MOTOR PERFORMANCE ABILITIES AND BODY MASS INDEX OF EGYPTIAN AND GERMAN CHILDREN

ABDEL KARIM, O., HÖKELMANN, A.

MAGDEBURG UNIVERSITY

**Introduction:** The growth process and development are ongoing according to the rhythm that is established by genetic inheritance and environmental factors. In addition the stages of motor development are the same for all children worldwide, but the developmental rate is influenced due to the special characteristics of the environmental conditions in which every child is growing. Therefore, the aim of this study was to identify the differences in motor performance abilities and BMI of Egyptian and German children. **Methods:** The participants are (n= 348) children aged from 6-8 years old in public primary schools in both Egypt (n=210) and Germany (n=132). The sample for the study has been selected randomly. The motor performance abilities have been assessed, and body mass index has been calculated using DMT 6-18 years old (Bös, 2009). **Results:** The results show that the level of motor abilities of German children is generally better compared to the Egyptian children. The differences between groups are significant ( $p=.000$ ). The general level of motor abilities of German children was average and BMI was normal ( $M=17.20$ ,  $SD=2.6$ ). However, for Egyptian children the level of motor abilities was below average and BMI was also normal ( $M=16.07$ ,  $SD=3.0$ ). The best motor ability was demonstrated in balance as well for Egyptian and German children. On the other hand the worst of Egyptian children was demonstrated in endurance ability and demonstrated by German children in power ability. **Discussion:** Although the BMI has the same level of Egyptian and German children, there are significant differences in the level of motor abilities between the groups. That shows the BMI has less influence on motor abilities in this age stage. The social-culture factors which are better in Germany compared to Egypt play a vital role in the level of motor abilities. The influential factors from the environment for instance living conditions, use of sport equipment or suitable places for motor activities are more influential factors (Daniel, 2007). In addition it's an indication of long-term commitment of the German children compared to the Egyptian children in physical education, sports, and motor activity (Booth, 1997). These make them physically better and they are healthier children (Bös, 2009). **References:** Booth, M., Macaskill, P., Phongsavan, P., Okeley, T., Patterson, J., Wright, J., Bauman, A., & Baur, L. ## INVESTIGATION OF EMOTIONAL INTELLIGENCE LEVELS ON PHYSICAL EDUCATION AND SPORTS TEACHING STUDENTS

YALIZ, D.

HEALTH SCIENCE

**Introduction:** At the present days, it is lay emphasis on important to exert effectively of emotional intelligence to establish relations with friends and acquaintances either business life or private life of persons. As regard as emotional intelligence height in persons who supplied self-identity and prove the needs, notice consuming and efficient, have command over one's temper establish relations with friends and acquaintances (Taskin, 2008). Therefore, the aim of this study was to investigate the emotional intelligence levels of Physical Education and Sports Teaching students at Anadolu University according to their gender, their class levels, their type of high school graduated fields and their sport branches. **Methods:** 107 students were formed the research universe. Data were collected by means of "The Emotional Intelligence Questionnaire" which is originally developed by Bar-On (1997) and later shortened and reorganised by Acar (2001) in Turkey. In the data analysis, "arithmethic mean and standart deviation" for numerical comparisons were used. In order to determine the differences among attitudes, t-test was used for two-way comparisons for independent groups and ANOVA was used in order to compare variables of groups more than two. In the statistical analysis, 0.05 was accepted as the significance level. **Results and Discussion:** As a result of this study there is no significant difference between their genders for personel skills, interpersonal skills, compatibility and general emotional state. On the other hand there is significant difference between their genders for overcome stress ( $p<0.05$ ). The result of this study is supported with literature (Acar, 2001). There is no significant difference between their class levels for compatibility and overcome stress. On the other hand there is significant difference between their class levels for personel skills, interpersonal skills and general emotional state ( $p<0.05$ ). The same results were founded by Mayer (2001). There is no significant difference between their type of high school graduated fields for personel skills, compatibility, overcome stress and general emotional state. On the other hand there is significant difference between classrooms for interpersonal skills ( $p<0.05$ ). The result of this study is supported with literature (Bender, 2006). **References:** Taskin, A. K. (2008). Beden eğitimi öğrencilerinde duygusal zeka düzeylerinin bazı degiskenlere göre incelenmesi. ## PROSPECTIVE ASSOCIATIONS BETWEEN CARDIOPULMONARY FITNESS AND ACADEMIC PERFORMANCE IN PRIMARY SCHOOL CHILDREN

CHEN, L.J.1, KU, P.W.2, WANG, J.H.2, LAI, T.T.2, YEN, Y.Y.2

1. NATIONAL TAIWAN COLLEGE OF PHYSICAL EDUCATION, TAIWAN 2. NATIONAL CHANGHUA UNIVERSITY OF EDUCATION, TAIWAN

**Purpose:** This study was designed to examine the relationships between cardiopulmonary fitness and academic performance among primary school children at the beginning of the six-grade and follow-up to the end of the six-grade. **Methods:** A total of 810 children from three primary schools in Taiwan participated in this study. Data including gender, mother's and father's educational levels, family structure, numbers of siblings, intelligence quotient, cardiopulmonary fitness, and body composition were collected at the beginning of the six-grade as the baseline data. Cardiopulmonary fitness was assessed by a 1600(boys)/800(girls)-meter run and was grouped into three levels: 'good', 'normal', and 'bad' according to the national fitness norm. Body composition was obtained through measured height and

weight and converted to body mass index. Three groups were categorized as 'underweight', 'normal weight', and 'overweight/obese' based on the age- and gender- specific cut-off points of the national definition of obesity. Academic performance was the mean scores of Language, Mathematics, Science and Social Studies, extracted from the school records and converted into T-scores. The ANOVA analysis was performed to examine differences in academic performance at the end of the six-grade between fitness groups. A multivariate linear regression for predicting academic performance at the end of the six-grade was undertaken adjusted for potential confounding factors at baseline. Results: Children in the good fitness group had greater academic performance at the end of the six-grade compared with those in the bad fitness group after the ANOVA analysis ( $p = .013$ ). In the multivariate model, gender, father's educational level, family structure, intelligence quotient, and baseline academic performance were significant predictors and accounted for 45.3% of the variance in academic performance at the end of the six-grade. Cardiopulmonary fitness showed no significant association with academic performance at the end of the six-grade after multivariate adjustments. Discussions: Previous research has provided a positive relationship between fitness and academic achievement (Castelli, et al., 2007; Chomitz et al., 2009). However, this study does not support the positive link between cardiopulmonary fitness and academic performance in multivariate analysis after one-academic-year follow-up. Further studies are necessary to investigate the longitudinal influence of fitness on academic achievement. References: Castelli, D. M., Hillman, C. H., & Buck, S. M., et al. ### **CAN TURNITIN™ OPERATE AS A FORMATIVE FEEDBACK MECHANISM TO IMPROVE WRITING DEVELOPMENT FOR SPORT AND EXERCISE SCIENCE STUDENTS?**

ELLISON, P.H., SPARKS, S.A.

EDGE HILL UNIVERSITY

**Introduction** The development of early drafts is a significant skill in enhancing writing practice. Some students may submit first or draft writing for assessment (Bean, 2001). The use of plagiarism detection software (Turnitin™) may offer opportunities to support writing development via the submission of early drafts (Davis, 2007) and formative feedback (Heinrich et al., 2005). The aim of this study was to evaluate the use of Turnitin™ to provide formative feedback via early submission and re-drafting, for a group of Sport and Exercise Science students (BSc Level 4). **Methods** Two groups of Sport and Exercise Science students ( $n=48$ ;  $n=63$ ) completed laboratory reports in two sequential years and gave written informed consent. The study was approved by the local ethics committee. Data was collected from academic results and an attitudinal web based questionnaire (using a 5-point Likert-type scale) designed to explore perceptions and experiences of the introduction of Turnitin™. An independent sample t-test was used to compare differences of the academic grades using SPSS (v.16). Results There were no significant differences in grades between cohorts ( $47.27 \pm 12.26\%$ - $46.54 \pm 13.38\%$ ) ( $t = .29$ ,  $df = 109$ ,  $p = 0.77$ ). Questionnaire Scale respondent data was 74% of  $n=63$ . Taking responses of 4 or more in the Likert scale (1-5 ascending) as an indication of overall agreement with a particular statement, the results show that Turnitin™ was perceived as a very effective way of submitting and correcting assignments by the majority of students (76.9% of respondents,  $4.2 \pm .4$ ). Majority of students (70%) reported the main purpose of Turnitin™ was to detect plagiarism. **Discussion** The suitability of Turnitin™ as a tool to promote writing development did not affect grades significantly. The perceptions of students indicate that Turnitin™ is an effective way of submitting and correcting assignments. The majority of students perceived Turnitin™ to be practical as a means of monitoring the originality of their work, although they shared a lack of understanding about the implications of the originality report. A significant aspect emerging from the questionnaire was that students identified the main purpose of the use of the software was plagiarism detection. It is useful to be mindful of the tensions that may emerge when attempting to make use of the dominant discourse of academic malpractice for the purposes of writing development. There were indications that the use of Turnitin™ acted as a deterrent to plagiarise rather than as support to develop writing for assessment for the majority of students. References Bean J. (2001). ### **PHYSICAL EDUCATION, PHYSICAL ACTIVITY AND ACADEMIC PERFORMANCE**

MARTINS, J., MARQUES, A., SARMENTO, H., CARREIRO DA COSTA, F.

TECHNICAL UNIVERSITY OF LISBON, FACULTY OF HUMAN KINETICS

**Introduction:** There is an ongoing debate among educators about the status of Physical Education (PE) in the curriculum, particularly in relation to more vocationally-oriented learning areas. **Objective:** The present study examined the relationship between physical activity (PA) and academic performance of Portuguese high school students, according to gender. **Methods:** A total of 245 boys (age  $17.7 \pm 1.0$ ) and 386 girls (age  $17.4 \pm 0.9$ ) from the 12th grade of three secondary schools participated in the study. Data was collected using a questionnaire about leisure time activities, PA participation (informal and formal), attitudes toward school and PE, and academic performance. Pearson's correlations were applied to identify the relationships between the number of weekly sessions of PA participation and the final mark obtained in 11th grade, in Mathematics, Language (Portuguese) and PE. In the Portuguese context, classifications range between 0 (minimum) to 20 (maximum). The lower reference for success is 10 values. Significance level was  $p < 0.05$ . **Results:** On average, boys presented lower academic performance than girls in Mathematics ( $12.6 \pm 3.2$  vs  $13.5 \pm 3.3$ ) and Language ( $12.3 \pm 2.2$  vs  $13.7 \pm 2.4$ ), but not in PE ( $16.9 \pm 2.2$  vs  $15.5 \pm 2$ ). Regarding PA, boys have reported to participate in more sessions per week than girls ( $4.9 \pm 3$  vs  $3.8 \pm 2.5$ ). In both genders significant and moderate correlations were established between Mathematics and Language ( $r = 0.518$  boys,  $r = 0.614$ ). There was also significant but low association between the scores obtained in PE and Mathematics ( $r = 0.355$  boys,  $r = 0.314$ ) and within PE and Language ( $r = 0.275$  boys;  $r = 0.382$ ). Moreover, significant but little correlations were observed between PA participation and PE marks ( $r = 0.223$  boys;  $r = 0.193$ ). Finally, it is worth noticing that there were no significant correlations between PA participation and both Mathematics and Language final marks. These results suggest that the practice of physical activity and the time allocated to PE do not adversely affect academic performance. **Conclusion:** Adding time to "academic" or "curricular" subjects by taking it from PE programs does not increase marks and might be detrimental to health (Trudeau & Shephard, 2008). In accordance to this investigation, this study highlights the fundamental role that schools and PE can assume in the promotion of active and healthy lifestyles. Physical education, school physical activity, school sports and academic performance. *International Journal of Behavioral Nutrition and Physical Activity*, 5 (10).

## THE IMPACT OF A HYBRID SPORT EDUCATION-INVASION GAMES COMPETENCE MODEL SOCCER UNIT ON OFFENSIVE DECISION MAKING AND SKILL EXECUTION ACCORDING TO PLAYERS' GENDER

SANTOS, D., FARIAS, C., ARAUJO, R., MESQUITA, I.

FADEUP

THE IMPACT OF A HYBRID SPORT EDUCATION-INVASION GAMES COMPETENCE MODEL SOCCER UNIT ON OFFENSIVE DECISION MAKING AND SKILL EXECUTION ACCORDING TO PLAYERS' GENDER Santos, D., Farias, C., Araújo, R., Mesquita, I. Centre of Research, Education, Innovation and Intervention in Sport, CIFI2D, FADEUP, Porto, Portugal Introduction The coalition of SE and IGCM takes into account the personal and social needs of students and the specificity of tactics on invasion games. Therefore, the purpose of this study was to examine the impact of the application of a hybrid SE-IGCM soccer unit on students' improvements in offensive decision making (DM) and skill execution (SE). Method A class of fifth-grade (17 girls and 9 boys) from a Portuguese elementary school participated in a 22-lesson soccer unit, which was designed following a hybrid SE-IGCM. One Pre-test (PTT) and two post-tests (PTT1, PTT2) measured the offensive decision making and skill execution obtained using the instrument developed by Blomqvist et al.(2005). Results From pre-test to post-tests 1 and 2 all students improved in holding the ball (DM) and dribbling (SE). From PTT to PTT2, girls improved in movements to a position to receive a pass (DM) and in passing (SE). At PTT boys have outperformed girls in passing (DM and SE), in holding the ball (DM), and in receiving the ball (SE). At both post-tests girls leveled scores with boys in passing (DM and SE); conversely, boys have overcome girls in holding the ball (DM), in dribbling (SE), and in shooting (SE). Discussion The impact of the program could be explained by the quality and quantity of students' opportunity of response that were envisaged by the learning tasks structure (Musch et al.,2005) which often gave students, time and space to decide and execute properly. Additionally, the tasks' structure (IGCM), encouraged the transferability of the skills to the game, allowing students to improve skills without losing the focus on game-problems solving (Tallir et al., 2007). The performance improvements were extended to both DM and SE suggesting that both are important and can determine the students' performance improvements in sports (Blomqvist et al., 2005). ## CAN JOB SATISFACTION EXPLAIN WHY A PHYSICAL EDUCATION TEACHER MORE THAN OTHER TEACHERS WANTS TO LEAVE THEIR PROFESSION

JAKOBSEN, A.

UNIVERSITY OF NORDLAND

Can job satisfaction explain why a physical education teacher more than other teachers wants to leave their profession? INTRODUCTION: Does Norwegian physical education teachers have a low score on job satisfaction, and do they experience their job situation so heavy loaded that they appraise to quit teaching the subject? Several studies have shown that job satisfaction is one important factor to avoid exhaustion and is essential to prevent job turnover. (Travers and Cooper 1996) Lack of status of the subject has also been claimed as a problem among physical education teachers. (Næss 1996, Armour and Jones 1998, Kougioumtzis 2006) Armour and Jones (1998) claims that the role of teacher education must be clearer. METHODS: 520 physical education teachers answered a validated questionnaire consisting of 150 questions concerning their job as a physical education teacher. Regression-analysis and path analysis were undertaken to check what independent variables had an significant impact on the two dependent variables "job satisfaction" and "probability of continuing teaching the subject" RESULTS : The independent variables that had the highest impact on "job satisfaction" ( $R^2 = 357 \text{ sig } ,01$ ) were education, how many lessons physical education they teach during a week, their physical fitness status, if they thought it was fun to teach the subject, the lack of problems with their pupils, lack of experience of physical and psychological stress in teaching and the feeling of competence as a physical education teacher. The independent variables that had the highest impact on "probability of continuing teaching the subject" ( $R^2=407 \text{ sig } ,01$ ) was: education, their experience of age and physical fitness, age, their thought of the importance of having a sport background, and lack of experience of physical and psychological stress in teaching the subject. Discussion: The teachers who studied physical education for one or more year, taught between 4 to 12 hours a week, training 3 or more times pr. week were the once who reported the highest teaching satisfaction and the probability of continue teaching the subject This indicates the importance of the choice of future physical education teachers characteristics/ criteria. ## REFLECTIVE PRACTICE AND PHYSICAL EDUCATION: A SYSTEMATIC REVIEW OF THE LITERATURE SINCE 1995

STANDAL, Ø.F.1, MOE, V.F.2

NORWEGIAN SCHOOL OF SPORT SCIENCES (1); SOGN OG FJORDANE UNIVERSITY COLLEGE (2)

REFLECTIVE PRACTICE AND PHYSICAL EDUCATION: A SYSTEMATIC REVIEW OF THE LITERATURE SINCE 1995 Standal, Ø.F. 1 & Moe, V.F. 2 1: NSSS (Oslo, Norway), 2: SFUC (Sogndal, Norway) Introduction The ability to reflect over one's practice is considered an important part of PE teacher education and PE teacher's work. In a review on this topic, Tsangaridou & Siedentop (1995) claimed that questions regarding the use and effectiveness of programs to enhance reflectiveness were unanswered. They also expressed hope that a future review would "assess the value of reflection from a firm evidentiary base" (p. 233). The purpose of this study was to review the literature published on reflective practice and physical education from 1995 to 2010. Method A systematic review of literature was conducted. The databases ERIC, ISI Web of Science and SportDiscus were searched for the combination of key words "physical education" AND "reflective practice", "reflective practitioner" or "reflective teaching". Inclusion criterions were: a) Journal article or book chapter; b) Physical education or education of physical education teachers as contexts; c) Available in English; d) Published 1995-2010. Results The articles included can be divided in conceptual and empirical articles. About 25% of the articles are conceptual, broadly arguing for why reflective practice is necessary, and how it can be promoted among PE teachers and PE students. In the empirical articles, the methodological quality varied

considerably, and a further division can be made between empirical work which is practice-based and low in methodological rigor, and empirical work with scientific quality. The majority of the articles belong to the latter group. For the most part, the empirical articles presented qualitative data. The review shows that the concepts reflection and reflective practice are used in very different ways by the different authors. Also, a concept like 'critical reflection' is used in various and sometimes contradictory ways. Discussion Compared to the study by Tsangaridou & Siedentop, it appears that the literature on reflective practice in physical education has increased. Yet, it is far from safe to say that we now have a "firm evidentiary base" to assess the value of reflection. By drawing on Wackerhausen's (2008) "structural anatomy of reflection", this review raises question about what the object of reflection is, and it draws attention to the knowledge base and concepts with which reflection takes place. In addition, it shows the various interests and motivations from which reflection takes place. Though educating unreflective practitioners is a bad option, this review points to a need to consider more closely the concept of reflection as well as its place and purpose in the education of PE students. References Tsangaridou, N. & Siedentop, D. (1995). *Quest*, 47, 212-237. Wackerhausen, S. (2008). RUMI, Institut for filosofi og idehistorie, Aarhus

## THE DEVELOPMENT OF PROFESSIONAL IDENTITY AMONG PRESERVICE TEACHERS. THE MEANING OF THE BOARD DIARY

CUNHA, M.1, GOMES, P.1, BATISTA, P.1,3, GRAÇA, A.1,3, PEREIRA, A.L.1,2

1 FADEUP (PORTO, PORTUGAL); 2 ISFLUP (PORTO, PORTUGAL); 3 CIFI2D (PORTO, PORTUGAL)

Introduction Professional Identity (PI) has served as an important construct in research on teachers and teaching[1]. Considering that the construction of the PI happens in the context of school[2], and the importance of professional training in that construction, the aim of this study was to capture the daily life of the pre-service teachers and the meanings they attribute to their experiences. Methods The participants were 11 pre-service teachers of Physical Education (PE), from 4 practicum's groups of academic year 2010-2011 (Faculty of Sport, University of Porto). They were invited in the beginning of the practicum to develop a board diary[3], with the events, experiences, thoughts and feelings regarding the practicum process. In the middle of the first semester, all the students participated in a focus group [4], conducted by 2 facilitators. The issues discussed were: which and what kind of situations were registered and why; what was the meaning given to these situations. The focus group was filmed and audio recorded with previous agreement of all participants. The confidentiality and anonymity was granted. The video and audio records were analyzed using NVivo 9. A thematic analysis was developed with the following themes: Type of registration; Situations most valued; Meaning of the previous situations. Results and conclusion Regarding the type of registration, the data shows that the pre-services teachers register class-room situations; feelings; anguishes; and issues related with the group of PE. The situations most valued involve the social interactions with their pupil and other teachers. Finally, the meanings attributed to the situations varies according to the school community and the pupil' level. The difficulty of still being a student and simultaneous the need to be a teacher was the feeling most observed within all the participants. FCT/PTDC/DES/115922/2009 References 1. ## MODERN PROBLEMS OF PHYSICAL EDUCATION OF YOUTH IN RUSSIA.

LIKHACHEV, O.

SMOLENSK STATE INSTITUTE OF PHYSICAL CULTURE

MODERN PROBLEMS OF PHYSICAL EDUCATION OF YOUTH IN RUSSIA. Likhachev O.1, Alpatskya E.1, Fomin S.2, Fomin A. 1. 1: Smolensk State Academy of Physical Culture, Sports and Tourism (Smolensk, Russia); 2: Russian State University of Physical Culture, Sports and Tourism (Moscow, Russia). Introduction. Transition to new social economical conditions in modern Russia led to the decrease of efficiency of the youth physical education. It has been the result of authoritative pedagogics that was carried out in the Soviet Union in condition of slow, but yet going on democratization of the country. New, not authoritative methods of physical education haven't been completely worked out yet. Methods During this investigation we inquired 1211 students of age of 18-22 from different higher educational establishments of the European of the part Russia: Smolensk, Orel, Kaluga. The questionnaire included 47 close and open type questions (items). The aim of investigation was to find out conditions under which we can involve students to different kinds of sport games. Discussion. The conducted questioning has shown that overwhelming majority of students (girls) (90,6%) realize (at least at the verbal kevel) the necessity of going in for recreative physical culture, but only 33% actually do it. The research has made it possible to reveal the expressed feature in choosing of a kind of recreative physical culture, which has been shown at the comparison of women, going in for an individual event-aerobics, and women going in for a team event- volleyball, basketball and others. Students (future businesswomen), whose main task is self – improvement: weight, reduction, appearance improvement, aspiration to improve health, etc., prevail in aerobics trainings. They consider that their future business career, family, life will depend on their good, physical condition, modern elegant appearance. Girl, going in for sport games, prefer to receive the emotional discharge from trainings, to change conditions, to expand contacts with other girls of the same age. The going gives them pleasure and they are fond of it. Result. This investigation showed that modern students don't clearly realize that important fact that a certain level of physical fitness should be constantly kept, that various diseases and abnormal conditions in elderly people are natural consequences of their ignorant treatment of their health in youth. It's the result of their irresponsible attitude to keeping fit in maturity.

## PHYSICAL EDUCATION ON VIRTUAL COMMUNITIES

ORIGUELA, M., LOPES DA SILVA, C.

METHODIST UNIVERSITY OF PIRACICABA

PHYSICAL EDUCATION ON VIRTUAL COMMUNITIES Origuela, M.A.1, Lopes da Silva, C.1 1: UNIMEP (Piracicaba , Brazil) Introduction Virtual communities on internet are a current phenomenon. They are sources of research and access to social discourses. The objective is to analyze discourses in two virtual communities: "I love Physical Education" and "I hate Physical Education" on Orkut website. The emergence of these communities constitutes an element for reflection about the signifiers assigned to Physical Education classes at school and the tradition of these classes in Brazil. Methods Literature search is performed based on classical and contemporary authors and

field research based on principles of ethnography, featuring a discussion eminently qualitative. Results The participants of the community "I hate Physical Education" use the virtual space for debates and complaints in Physical Education classes at school. It was realized that in "I love Physical Education" communities, the users use the space mainly for advertisements. Discussion New phenomena, such as the Internet virtual communities "I love Physical Education" and "I hate Physical Education" in the Orkut social network site, are elements for reflection in this direction and to debate problems related to school lessons on Physical Education. In our culture, it is common to hear people recalling with joy their lessons of Physical Education and, also, to hear people who relate to these lessons with much regret or anger. This fact can be associated to the experiences that students had in their Physical Education classes on school and the activities performed in leisure moments. This work contributes to review the concepts and values by students and professionals working in the area of Physical Education and Leisure. References Daolio, J. (1996). ## MIDDLE SCHOOL PUPILS ON THE PURPOSE AND EVALUATION OF PHYSICAL EDUCATION

BOGNÁR, J., OLÁH, Z.S., RÉVÉSZ, L., KOVÁCS, T.L., FÜGEDI, B.

SEMMELEWIS UNIVERSITY, FACULTY OF PHYSICAL EDUCATION AND SPORT SCIENCES (TF)

Introduction The review of literature provides evidence that physical educators rely on subjective measurements to evaluate student learning. Research also shows that physical education teachers are concerned with behavior rather than with how much students learn. Our aim was to examine 10-14 years-old pupils' views and experiences on 1) the aim of PE lessons, 2) the importance of PE lessons, 3) tendencies in PE lesson evaluation and the extent to which they are accepted, 4) their perceptions on their mark. Methods The sample consisted of 1218 pupils between 10 and 14 years of age (67% return rate). All filled out an open-ended questionnaire. Distribution of gender, age and PE teachers' gender were equal. In the analysis categories were coded and grouped in themes according to their characteristic features, and then non-parametric statistics were used. Results 36.5% of middle school pupils consider the purpose of PE as the improvement of physical condition. According to 35.3%, PE lessons provide physical exercise that cannot be done elsewhere, 20.5% considered that the aim of PE is to promote health and a healthy lifestyle. Most pupils believe that regular PE lesson is of high importance (90.8%). Those students who had three or more PE lessons a week mentioned less frequently exercise as PE's main purpose and more frequently healthy lifestyle ( $p < 0.0001$ ). Pupils of female PE teachers indicated more frequently that PE is an important subject than those of male PE teachers ( $p < 0.0001$ ). PE teachers formally assess and evaluate the techniques and tactics of sports, the development of physical condition and coordination (45.3%) and „everything we do at PE lessons“ (35.3%). 84.3% of students accepted and approved the present form of grading and evaluation system ( $p < 0.0001$ ). 83.6% has a 4 or a better mark in PE (5 being the best and 1 being the worst) ( $M = 4.338 \pm 0.7025$ ). 93.5% of the pupils accept their own PE mark ( $p < 0.0001$ ). The 7th and 8th grade pupils didn't agree with the purpose of evaluation, 5th grades students have a better PE mark than all other students ( $p = .012$ ,  $p = .004$ ). Boys believe that performance and achievement are assessed/evaluated in the PE lessons ( $p = .036$ ) and boys also had significantly better marks than girls ( $p = .012$ ). Those pupils who had a female PE teacher mentioned more frequently that they were evaluated on the basis of their own advancement than the pupils of male PE teachers ( $p < 0.001$ ). Pupils who have more PE lessons a week have better marks ( $p < 0.0001$ ). Those not doing regular extracurricular sports tend to disagree with the form of evaluation ( $p = .015$ ). The marks of those who did sports were also significantly better than of those not doing sports ( $p < 0.0001$ ). Conclusions Results show that it is worth consulting the pupils in order to improve the quality of the physical education class. The current form of evaluation of PE as a subject area seems to be appropriate. According to our expectations, the results can be very well used well in the dispute regarding the question of assessment and evaluation in physical education.

## PHYSICAL EDUCATION CAN INFLUENCE THE LIFESTYLES OF GIRLS?

NEVES, R.

AVEIRO UNIVERSITY

Introduction The nature of personal experiences in Physical Education (PE), can influence the choices of lifestyles as adults (1), but also as future teachers and educators. Note that PE quality programs help to maintain positive perceptions of students (2). It is therefore important to know and to characterize the perception that future educators and teachers have about the influence of experiences in physical education (3), for a more active lifestyle and healthy. Methods A questionnaire was applied to 277 students girls from 1st year of Bachelor in Basic Education from the University of Aveiro over 4 academic years (2007/2008 to 2010/2011), using a scale of perception (level 1 - not at all ... 7 - enough) and explanation of the reasons. Data were analyzed using descriptive statistics and content analysis. Results 60.6% of respondents identified themselves with a perception of the influence of PE between level 4 and 5. The scale value was less than 1 (2.2%), followed by 2 (3.3%) and 7 (3.3%). Level 4 is the most expressive in all of four years' study. Only in 2010/2011 the level that is no longer the 4 to be the 5. Level 3 grows smoothly over the years (from 11.1% to 20%). The category specific effects of PE was the most significant and emerge as the main justification ('The PE has prepared me and encouraged me to enjoy sport', 'because I developed a taste for sport which until then had not', 'because I realized the importance of physical activity', 'He taught me many games and have developed some capacity. It made me gain appreciation for various sports' or 'because I learned different sports'). Discussion The PE seems to have a strong influence on the lifestyles of the students, indicating a neutral trend or not strongly marked. Despite the results the reasons given as justification to focus significantly on the positive aspects associated with the specific effects of PE. These results should make us reflect on the training offered at the EP, especially for girls. (1) TRUDEAU, F., LAURENCELLE, L. & SHEPHARD, R. ### PP-SH07 Sociology of Physical Activity

#### CHILDREN PHYSICAL ACTIVITY PARTICIPATION AND THE PERCEPTION OF THEIR PARENTS' WEEKLY PHYSICAL ACTIVITY

MARQUES, A., MARTINS, J., SARMENTO, H., MARTINS, M., COSTA, J., ONOFRE, M., CARREIRO DA COSTA, F.

TECHNICAL UNIVERSITY OF LISBON, FACULTY OF HUMAN KINETICS

Introduction: Identifying psychological influences affecting children's behaviour about physical activity (PA) is important to understand individual differences in children's activity participation. Objective: This study sought to examine the relationship of children PA behaviours and the perception they have of their parents' weekly participation in PA. Methods: A total of 251 boys (age  $10.7 \pm 0.7$ ) and 164 girls ( $10.5 \pm 0.7$ ), age ranged between 10 and 12 years old, participated in the study. The informed consent was obtained from each participant and their parents. Data was collected using a questionnaire used on international research project on children's lifestyles. A two-way ANOVA was used to determine main effects and interactions of children's perceptions of their parents' PA participation on children PA participation. Significance level was  $p < 0.05$ . Results: On average boys spent  $4.2 \pm 2.8$  hours in PA a week and girls  $3.1 \pm 2.3$ . Boys and girls with both active parents were more involved with PA ( $4.21 \pm 3.1$ ) than those whose parents were inactive ( $3.4 \pm 2.1$ ). In both genders the most active children had the perception that their fathers practiced weekly PA. ANOVA revealed no significant interaction for children's perception of their father and mother PA participation (boys,  $p = 0.92$ ; girls,  $p = 0.95$ ). For girls, non significant differences were observed neither for the perception regarding fathers' PA participation ( $p = 0.18$ ), nor for the perceptions towards their mothers ( $p = 0.24$ ). However, a significant difference was found between boys who perceived that fathers were active and those who said their father were inactive ( $F(1,239) = 4.96$ ,  $p = 0.03$ ). Conclusion: Children's participation in PA is not significantly related to their perception of parental involvement, with the exception of boys who perceived their fathers as actives. However, despite not having found significant differences, we could observe a tendency that points to a relation between the perceptions that parents are active with the amount of PA practiced by children.

#### TOURISM IN THE PERSPECTIVE OF SACRUM

KOSIEWICZ, J.

JOSEF PILSUDSKI UNIVERSITY OF PHYSICAL EDUCATION

Tourism in the Perspective of Sacrum Prof. Dr. Jerzy Kosiewicz Josef Pilsudski University of Physical Education in Warsaw Regardless from the fact if free time is considered from a religious or a non-religious viewpoint, it is possible to proclaim that there are two kinds of possible relations between tourism and sacrum: 1. Concerning wandering, which can have, firstly, strictly religious (that is: pilgrimage) character and, secondly, non-religious, cultural character connected with studying religion. 2. Connected with reception of nature during outdoor tourist wandering. Those experiences can have threefold qualities: parareligious, nonreligious and religious ones. That type of sacral experiences of spontaneous qualities appear solely because of direct influences of nature and not under the influence of man's works and religious objects which have been appointed by him and which are approved by a given community. A proper example in that respect is constituted by Tatra and sea travels of Mariusz Zaruski – a Polish seafarer and mountaineer from the turn of the 19th and the 20th century. In his considerations on tourism he refers to the simplest solutions characteristic for general assumptions of Hellenistic philosophy of nature. It concerns, among other things, Pythagorean harmony and Heraclitean mind of the world as well as hylozoism or animism of Ionic philosophers of nature, which obviously stem from superficial empirical cognitions, perceptions and observations of nature; from the simplest (from the present viewpoint) explanations of inductive and intuitive character.

#### THE ROLE OF SOCIAL SUPPORT IN 17-18 YEARS OLD IN TIRANA.

SHEHU, A.

UNIVERSITY OF SPORT OF TIRANA

Shehu, A.1, Spahiu, M.1, Qeleshi, A.1 1: UNIVERSITY OF SPORT OF TIRANA Introduction: Social Support has been recognized for a long time in the behavioral science as an important adjunct to therapy(1). Social support can come from a variety of sources (friends family, teacher) and the goal is to identify and nurture relationships that can provide this type of support (2). How is the situation in our selected group? Objectives: To see how much do they take part in life, as a member, as a part of the group, as a part a society, specially for their delicate ages in our long and delicate transitions Subjects: Proximately 194 boys and girls 17-18 years old are selected as a part of our study, from famous High Schools ("Partizani" – "Arben Broci") in the center of Capital .. Methodology: SSS(The social Support Scale)questionnaire assessment the Social Support has been applied. (Poul M.Insel and Walton T .Roth 1988). Results: Rating Total score female male total High Support 70 or more ---- 0 % 0 % 0 % Moderate Support 40-69 --- 48 % 50 % 49 % Low Support less than 40 --- 52 % 50 % 51 % Discussion: The situation from questionnaire speak clear that it is no good for the half of students .Data show that 51 % in total are at Low Support which suggest that they lack the minimum support structure to counter the negative effects of stress. In our information study we tried to be honest, true and simple as a postulate in science said . References- 1.Poul M.Insel and Walton T .Roth. Core Concepts in Health. Fifth Edition . 2: 36-38. 1998 2. 1- Charles B.Corbis, Ruth Lindsey, Greg Welk. Concepts of Physical Fitness ,2000;19: 368-370.

### PP-SH08 Personality, Motivation, Coherence

#### SPORTS ACTIVITIES AND SENSE OF COHERENCE AMONG COLLEGE STUDENTS

ENDO, S., KANO, H., OISHI, K.

RIKKYO UNIVERSITY

Introduction Increased depressive symptoms and anxiety as well as a loss of confidence and decreased self-esteem have been noted among young adults in Japan. In this background, more attention has been paid to salutogenesis and Sense of Coherence (SOC) which

was theorized by Antonovsky (1979, 1987). Salutogenesis is the theory that examines why people can stay healthy and which focuses on maintenance and promotion of health. SOC refers to a perception and sense of one's experiences in the world in which he or she is living is coherent, consistent, reasonable, and comprehensible. It is known that if people have strong SOC, they can mobilize General Resistance Resources (GRRs) and cope with stresses successfully. Former studies suggest the possibility of increasing one's SOC through the acquisition of positive psychological states and various psychological skills brought about by sports activities. The purpose of this study was to compare the level of SOC in athletes to that of non-athletes among college students. Methods Subjects were 732 college students (315 males, 417 females; mean age:  $19.4 \pm 1.4$  years). SOC was measured by using the Japanese version of SOC-13. This questionnaire reveals the degrees of SOC and the three elements of SOC (sense of comprehensibility, sense of manageability, and sense of meaningfulness). Additionally, sports activities among the subjects were surveyed in terms of their affiliated athletic organizations, sporting events, and frequency of play. Results Subjects were categorized into three groups, i.e., athlete, semi-athlete, and non-athlete groups. The Kruskal Wallis test showed significant differences in the SOC and sense of meaning scores among the three groups ( $\chi^2=12.35$ ,  $11.80$   $p<0.01$ ). Additionally, the Steel-Dwass test for multiple comparisons showed significant differences between the athlete and non-athlete groups ( $t=3.22$ ,  $3.24$ ,  $p<0.01$ ), and the semi-athlete and the non-athlete groups ( $t=2.50$ ,  $2.41$ ,  $p<0.05$ ). Discussion Our results showed the consistent and strong relationships between sports activities and SOC. Additionally, these results suggested that the successive sports activities elevated SOC, and the athlete and semi-athlete have more desirable mental attitude than the non-athletes. References Antonovsky A. (1979). *Health, Stress and Coping. New perspective on Mental and Physical Well-being*, Jossey-Bass, San Francisco. Antonovsky A. (1987). *Unravelling the Mystery of Health. How People Manage Stress and Stay Well*, Jossey-Bass, San Francisco.

## A RESEARCH ON THE ANXIETY AND AGGRESSION LEVEL OF TEAM AND INDIVIDUAL SPORTSMEN

YILDIZ, M.

KARAMANOĞLU MEHMETBEY UNIVERSITY

A RESEARCH ON THE ANXIETY AND AGGRESSION LEVEL OF TEAM AND INDIVIDUAL SPORTSMEN Yıldız, M.1, Şahan, H. 2, Tekin, M. 3, Güllü, M.4, Devecioğlu, S.5 1 Karaman, Turkey, 2 Karaman, Turkey, 3 Karaman, Turkey, 4 Malatya, Turkey, 5 Elazığ, Turkey Introduction Aggression is a crucial problem for us with which we come across at all stages of the social life, in street, in school, within family and sports environment. And depending on this issue, factors affecting aggression must be considered. Level of anxiety of is considered as the most recognizable one among these factors. For this reason, investigation for the anxiety and aggression level of sportsmen doing individual and team exercises is aimed in this study. Method The groups included in this study are consisted of 82 team sportsmen and 65 individual sportsmen and totally 147 sportsmen actively in physical training and sports academy from Karamanoğlu Mehmetbey University, Selçuk University, Gazi University and Akdeniz University. To reach the aim of the research; State-trait Anxiety Inventory developed by C. Spielberger (1970) and Aggression Inventory developed by Kiper (1984) are used. In the solution and the interpretation of the data; Kolmogorov-Smirnov test and t test are used and significance is determined as  $P<0.05$ . Results It is found that level of continuous anxiety is higher in team sportsmen than individual ones ( $P<0.05$ ). Level of destructive aggression, recklessness and aggression in general of team sportsmen is higher than individual ones ( $P<0.05$ ). Level of passive aggression in individual sportsmen is found higher ( $P<0.05$ ). Discussion As the result of this study; it is found that level of continuous anxiety is higher in team sportsmen than individual ones (Adam et al 2009). The findings in this study were parallel with the current study. Level of destructive aggression, recklessness and aggression in general of team sportsmen is higher than individual ones. It is thought that there may be some aggressive behaviour depending on the qualities of the sportsman, trainer's tactics, and sports fan and media pressure. Level of passive aggression in individual sportsmen is found higher. Many reasons, such as individual sportsmen's taking decisions on their own, the intensity of their social or psychological problems, not achieving their expectations from sport and how are they affected from this failure, their tendency towards these kind of behaviours, partially. ## SPORTS ACTIVITIES AND THE BIG FIVE PERSONALITY FACTORS

SHINTANI, K., ENDO, S., OISHI, K.

RIKKYO UNIVERSITY

Introduction Many researchers have studied personality of athletes. In many cases, those studies reported that the athletes were more extroverted, and less depressive and/or anxious than non-athletes (de Moor et al., 2006). Additionally, longitudinal studies have shown that the sports activities enhance extroversion of the subjects. Therefore, it is suggested that the sports activities and personality are closely connected. However, there are few reports in which the relationships between the sports activities and the Big Five personality factors (extroversion, neuroticism, agreeableness, conscientiousness, and openness) are studied. The purpose of this study was to clarify these relationships. Methods The subjects were 732 college students (315 males, 417 females; mean age:  $19.4 \pm 1.4$  years). We asked them about their daily sports activities and examined their personalities by questionnaire based on the Big Five personality factors (Nettle, 2007). They were divided into three groups (athlete, semi-athlete and non-athlete groups). Then, Kruskal-Wallis test was used to examine the differences of the personality factors in those three groups. Results The Kruskal Wallis test showed significant differences in the neuroticism ( $z=18.38$ ,  $p<0.001$ ), the conscientiousness ( $z=9.85$ ,  $p<0.01$ ), and the openness scores ( $z=6.61$ ,  $p<0.05$ ) among the three groups. Additionally, the Steel-Dwass test for multiple comparisons showed significant differences between the non-athlete group and the athlete or the semi-athlete groups in those personality factors. Discussion From the above results, it was suggested that the sports activities were related to the parts of the Big Five personality. Former studies have shown that the athletes are more extroverted than that in the non-athletes. However, this study did not support them. References de Moor, M. H. M., Beem, A. L., Stubbe, J. H., Boomsma, D. I., and De Geus, E. J. C. (2006). Regular exercise, anxiety, depression and personality: A population-based study. *Preventive Medicine*, 42:273-279. Nettle D. ## THE HUNGARIAN ADAPTATION OF PERCEIVED MOTIVATIONAL CLIMATE IN SPORT QUESTIONNAIRE-2

REVESZ, L., BOGNAR, J., GECZI, G., TRZASKOMA-BICSERDY, G., KOVACS, T.L.

SEMMELEWIS UNIVERSITY FACULTY OF PSYCHICAL EDUCATION AND JOZSEF EOTVOS ACADEMY

**Introduction** Sport scientific researchers are interested in the influencing factors of success in sport for a long time. The physiological, physiological, biomechanical etc. aspects of achievement are well known, however it does not give a complex view on all important factors. For participation in sport and for high achievement the personality of sportsmen seems to be also very important factor, that is why we think it is worth to measure and find out all the contexts in that field. The purpose of the present study was two-fold. Firstly, enlarge the Hungarian resources of Social Sciences in the domain of sport furthermore add a new questionnaire in Hungarian sport science research which can be able to compare international differences between athletes. Secondly, determine the validity and reliability of the Hungarian version of Perceived Motivational Climate in Sport Questionnaire (H-PMCSQ-2). Large number of literature can be found about the motivations and aims of athletes. The PMCSQ-2 questionnaire is widely used in sport, convenient to measure the motivational orientation, motivational climate (Task-Involving, Ego-Involving), and achievement goals. **Methodology** The adaptation of the questionnaire was achieved through a long process. First of all it was tested with a smaller sample (N=150) of athletes /Study 1/. Taking the conclusions of that measurement the questionnaire was corrected and tested with a bigger sample (N=917, mean age 16.32±1.21 years) as well /Study 2/. In Study 2. elementary and high school students were selected. 464 of the students (50,6 %) were actually pursuing sports, 352 of them (38,4 %) were previously pursuing sports and 101 students (11%) were never pursuing any sports. Analyzing the results we were looking for significant differences between the measured three (3) groups. **Results** Study 1. The Cronbach-alfa value of the whole questionnaire was 0,8, in the case of Task-involving scale 0,85 and Ego-involving scale 0,82. All cases showed strong correlation between higher-order scales and subscales, as well as between the items of subscales. Both the Task and Ego-involving subscales showed correlation with the higher-order scales. Study 2. ANOVA showed no significant differences based upon the type of sport. For gender analyses ANOVA was used, and significant differences were found. Analyses showed significant differences in the case of effort/improvement (Task) and punishment for mistakes (Ego) subscales. Further analyses showed significant differences in both Task- and Ego-involving subscales based upon team or individual sports. One subscale, the effort/improvement did not show differences in this case. **Conclusion** Based upon the statistical analyses made for proving the validity and reliability of the questionnaire, we can conclude that the Hungarian version can be widely used in Social Sciences for measuring motivational climate as well as Task- and Ego-orientation.

## SPECIALIZATION IN YOUTH BASKETBALL: THE ROLE OF SPECIFIC MOTIVATION

GONÇALVES, C., COELHO E SILVA, M.1, CARVALHO, H.1, FIGUEIREDO, A.1, GONÇALVES, Â.2

1:UNIVERSITY OF COIMBRA;2: EBI

**Introduction** The specialization years are seen as a decisive moment to lift the skill level, athletic readiness and commitment (Gonçalves et al., 2009). Selection and orientation of talent has been strongly dependent of biological and motor variables. The purpose of this study is to describe the achievement and motivation variables that can explain the belonging to an elite competitive level of young basketball players. **Methods** Eighty-two basketball players under 16 years fulfilled the WOFO (Spence & Helmreich, 1983), and an adapted version of the DPMQ (De Bruin, Rikers & Schmidt, 2007). Forty players were engaged in high performance centres and forty-two played in national level clubs. The WOFO assesses three dimensions of achievement: work, mastery and competitiveness. The DPMQ assesses two dimensions of deliberate practice: will to compete and will to excel. A random forest analysis between elite and national level players was performed (Breiman et al., 1984). **Results** The measurements rank Will to Excel, Winning, Mastery, Competitiveness, and Work in decreasing order of importance, consistent with the results of a single decision tree. In both types of analysis, the competition-related variables play the main role to discriminate the athletes by level. The task orientations, like Mastery or Work discriminate the players in a much lower percentage. **Discussion** The results confirm previous studies (Gonçalves et al., 2009) that did not find a significant effect of achievement variables (work, mastery) on specialization. These findings suggest that a self orientation to excellence may play a crucial role in persistence in practice in order to achieve higher standards in competition. The will to excel can be considered as a condition to engage in more specialized practice. The inclusion of measures of specific motivation in the specialization process for elite performers is useful and relevant. However, the studies with team sports are scarce and must be a topic in future researches. The assessment of the path to expertise only through motor variables or through the accumulated hours of deliberate practice is limited. The use of a more comprehensive model is needed. **References** Breiman, L., Friedman, J. H., Olshen, R. A. & Stone, C. J. (1984). Classification and Regression Trees (1st edition). ## PHYSICALLY ACTIVE TEENAGERS MORE PRONOUNCED EGO- AND TASK-ORIENTED THAN SEDENTARY PEERS

SOLLERHED, A.C., APITZSCH, E.

KRISTIANSTAD UNIVERSITY/LUND UNIVERSITY

**Introduction** Successes and failures can be explained by a variety of causes – attributions, which affect not only expectations of success or failure but also emotional reactions (Biddle et al, 2001). Performance goal can be either performance-oriented with focus on comparing themselves with others, or task-oriented where the focus is to improve in comparison with themselves. In some situations, you can be both ego-oriented and task-oriented, but most tend to be either ego-oriented or task-oriented (Weinberg & Gould, 2010). **Methods** A questionnaire including questions about ways of living, self-reported physical activity (PA), membership in sport clubs, attribution style, attitudes towards school physical education (PE) and to PA in general. The sample was 659 teenagers, 15-16 years old, in comprehensive schools in Sweden. Goal orientation was investigated by the TEOSQ form (Duda & Whitehead, 1998). The chi squared test and the Student's t-test were used in the statistical analyses. **Results** The teenagers who reported high levels of PA had higher scores in ego-orientation than their sedentary peers (20.5 vs 18.1; p=0.001) and in task-orientation (29.4 vs 26.8; p<0.000). Teenagers who were members in sport clubs had higher scores than non-members in ego- (19.0 vs 17.6; p=0.004) and in task-orientation (28.7 vs 25.0; p<0.000). Students with positive attitudes towards PE had higher scores in both ego- (19.3 vs 17.7; p<0.000) and in task-orientation (28.3 vs 26.2; p<0.000) than students with less positive attitudes. **Discussion** Students who were physically active in leisure time seemed to be more pronounced in both ego-and task-orientation than their more sedentary peers. Being ego-oriented, when combined with high task-

orientation, has been shown to be associated with high motivation (Wang & Biddle, 2001). Ego-orientations interact with perceptions of competence and task-orientation is connected with self-improvement and effort (Weinberg & Gould, 2010). The sedentary teenagers were more gathered "in the middle", not high in ego-, nor in task-orientation. Students with the combination low-task low-ego are difficult to motivate in the PE situation. Those students are not task-oriented enough to put any effort to do PA, and they are not ego-oriented enough to compete and to care about the self-perceived competence. ## MOTIVATIONAL FACTORS AND SPORT PARTICIPATION IN EARLY ADOLESCENTS

NICOLOSI, S., SCHEMBRI, R., MANGO, P., PIGNATO, S.

KORE UNIVERSITY OF ENNA

**Introduction** Several studies have shown that individuals invest their psychological energies in actions that promote a positive state of consciousness (Csikszentmihalyi & Csikszentmihalyi, 1988). Everyone searches, selects, and replicates all the activities that support the increase of good practices, during their life. According to cultural beliefs and daily commitments, the activities that produce positive emotions became good practises. This research aims to explore motivation and involvement in sport or physical activities of pre-adolescents in the district of Enna (Sicily, Italy) and to study the relationships between Physical Self and sport or physical activities. **Methods** The present study involved 190 students attending the 8th grade of middle school in the district of Enna. The instruments used were the following: - the Sport and School Questionnaire by Pignato & Nicolosi (2011, in press); - the Italian translation of Physical activity Motivation Questionnaire by Sirard & coll. (2006); - the Italian version of Physical Self-Description Questionnaire by Scarpa & coll. (2010). **Results** Our study identified motivational factors, such as competition, social, fitness, and skills, associated with sports program participation and attrition in middle school students. **Discussion** Since the 80's the study of motivation has affected the field of sport psychology. Some studies have shown the benefits of the practice of physical activity: it improves the perceived well-being and the degree of life satisfaction (O'Connor & coll., 2000; O'Neal & coll., 2000). Overall, our data suggest that the habits of the preadolescents involved in this study can be successfully classified into healthy and wrong habits finally providing a valuable tool to improve sport programming in the district area. **References** Csikszentmihalyi M. & Csikszentmihalyi I. (Eds.) (1988). *Optimal experience: Psychological studies of flow in consciousness*. Cambridge University Press, New York. O'Connor P.J., Raglin J.S., & Martinsen E.W. ## INDIVIDUAL FEATURES IN EXTREME SPORTS

DELITALA, L., CURRELI, G., FANUNZA, L., GUICCIARDI, M., TARANTINI, F.

\*DEPARTMENT OF PSYCHOLOGY-UNIVERSITY OF CAGLIARI; \*\*ASL. 8 CAGLIARI

**Introduction** Risk behaviors are defined as daring conduct that may endanger physical, psychological and social well-being in the short and long term. These behaviors include the practice of extreme sports, different disciplines that share research of the physical limits and risk taking. The scientific literature has highlighted as psychological determinants of extreme practice the personality trait sensation seeking (Boyd & Kim, 2007; Asci et al, 2007) and the emotions' regulation system (Gray, 1999). This study investigated risk perceptions, emotions' regulation and some personality traits in a sample of adolescents and young adults engaged in various extreme sports. **Methods** The total sample consists of 102 young people (71 males; 31 females) aged from 16 to 28 years ( $M=22.23$ ,  $SD=3.31$ ): 49 practicing extreme sports and 53 belonging to a control group. Participants completed following tests: Sensation Seeking Scale, Positive and Negative Affect Schedule, Behavioral Activation Scale/Behavioral Inhibition Scale (BAS/BAS), Physical Risk Assessment Inventory, Flow State Scale. To evaluate the differences between the groups we conducted a multivariate analysis of variance (MANOVA) using the group's membership and gender as independent variables, and the average scores of scales as dependent variables. **Results** The group of extreme sports has a greater orientation toward the BAS, with significantly higher values in all its subscales. It also reported the highest scores in positive affect, challenge balance skills and thrill and adventure seeking. There were also significant differences by gender: males have higher scores on clear goals, unambiguous feedback and thrill and adventure seeking; females showed a BIS score similar to BAS score and significantly greater than males. **Conclusions** Young people who practice extreme sports have a greater impulsivity (as evidenced by BAS scores), positive affects linked to dangerous experiences and a greater propensity for thrill and adventure. Women seem to represent a more healthy model to live the extreme sports adventure, since they show a greater balance between the behavioral activation systems (BAS/BAS). **References** Asci, F. ## IS IT BETTER SELF-MOTIVATION OR COACHING ADVICE IN ORDER TO ACHIEVE A GOAL DURING THE SHOUTOUT PROCEDURE?

PAPAMARGARITIS, T., ZACHOULOU, D.

KAPODISTRIAN UNIVERSITY OF ATHENS

**IS IT BETTER SELF-MOTIVATION OR COACHING ADVICE IN ORDER TO ACHIEVE A GOAL DURING THE SHOUTOUT PROCEDURE?** Papamargaritis Th., Zachoulou D. Department of Aquatic Sports, Faculty of Physical Education and Sport Science, University of Athens Greece **Introduction** An action that helps to shape the outcome in a water polo match is penalty. Actually it is a very difficult situation. Penalties are charged to the defending player when he is making a hard foul in the defensive zone of 5m, facing to the terminal. The execution of

penalty takes place in a distance about 5m from the terminal without the mediation of a defensive player except from the goalkeeper. The shoot happens after the referee's command. Case-Purpose The purpose of this study is to determine whether the shooter player, selects only the angle to shoot without being affected by an agent or if he chooses an angle after the coaching directive. The coaching directive always mentioned about the angle that a player has to shoot in order to achieve a goal. We will try to understand if self-motivation or the adherence to coach instructions is more effective, by counting the reaching rates goal on both cases. Method For the purpose of research, took part three of the top teams in the age division from 17 to 20 years in Greece. Each team was consisted of 15 athletes. After a stage of 20 minutes warm each player was asked to perform 10 penalty shoots. Coach, was back of the terminal observing goalkeeper's movements and position using a beam of light, he was directing the shooter player about the angle he has to shoot. Angle's suggestion was instantaneous before referee's whistle. Then we measured the percentage of the athlete's self-reactive and the percentage of those who followed the coach's direction. After all we count down the percentage of the successful penalties. Results According to final results we conclude that 24% of the total efforts of players are acting contrary to coach's suggestion. To be more specific, the percentage of goals that achieved, when athletes self-motivated was 58, 1% of the total. The remaining 76% indicated to the angle that coach chooses as the best choice in order to achieve a goal. About the 79, 8% of those attempts resulted in goals. Conclusions We are observing that the largest executions players follow the command even that is right or wrong. This shows that coaching direction even more in underage water polo player provides a form of security to the players. Between those two cases, coach's suggestion and self-motivation, the difference in rates that resulted in goals was 21, 7%. According to this difference we conclude that the shooters must follow coaching instructions because research's results showed that better results achieved on those ages.

#### POINTS OF VIEW: PROFESSIONAL PLAYERS' AND MANAGERS' PERCEPTIONS OF VENUE IN FOOTBALL

ANDERSON, M., WOLFSON, S., NEAVE, N.

*NORTHUMBRIA UNIVERSITY*

Points of View: Professional Players' and Managers' Perceptions of Venue in Football Anderson, M.A, Wolfson, S. & Neave, N. (Northumbria University, UK) Introduction An abundance of studies are in existence exploring the home advantage phenomenon from a quantitative perspective, most of them highlighting factors such as crowd support, referee bias, familiarity, travel, rule factors and more recently a hormonal response as determinants of why teams perform better at home than they do away (See Courneya & Carron, 1992; Pollard & Pollard 2005 for review). However, despite this plethora of research little is known about the belief systems which operate from key personnel regarding the home advantage phenomenon. The aim of the study was to explore the beliefs of professional football managers and players in ascertaining their perceptions of why teams perform consistently better at home than away. Methods An opportunity sample consisting of three male professional football players and six male professional football managers participated in a semi-structured interview designed to ascertain their beliefs and perceptions of the home advantage. Results Thematic analysis arising from the interviews revealed support for previously identified factors comprising the home advantage including familiarity, travel, crowd and referee factors. There were also two newly identified higher order factors, experience and control which were deemed to impact upon these original factors. An extension of Pollard and Pollard's (2005) conceptualisation of the home advantage is also proposed. Discussion The present study provides an insight into the key beliefs held by football managers and players providing a unique insight into the home advantage phenomenon. The present study supports the findings of quantitative research in the area (travel, referee bias, familiarity, physiological response) whilst additionally uncovering some of the more prominent belief systems which underpin these well-known factors. The findings also provide suggestions for further research with a view to extending knowledge in the area. References Courneya, K. S. & Carron, A. V. (1992). #### JOB STRESS AND BURNOUT IN ELITE SOCCER COACHES

LUNDKVIST, E.I, HASSMÉN, P.I, GUSTAFSSON, H.2

*UMEÅ UNIVERSITY*

Introduction Elite coaches work in a constantly challenging environment. Strain and exhaustion associated with the coaching role has drawn interest, not the least because of the significant number of persons leaving the coaching ranks every year (Raedeke, 2004). The purpose of this study was to see whether job stress in a group of elite soccer coaches is related to differences in emotional exhaustion. Method The participants consisted of 47 elite soccer coaches from the two highest male leagues and the highest female league in Sweden. The coaches individually completed two instruments: Maslach Burnout Inventory Educators Survey (Maslach et al., 1996) as modified for coaches (Kelley, 1994), and the Job Stress Survey (JSS; Spielberger & Vagg, 1999). Three JSS-scales were used: JS-S measuring the perceived severity of 30 items on a 1-9-scale in relation to a reference item with a constant of 5. Secondly, JS-F measuring the frequency of occurrence of the 30 items during the last six months, from 0 to more than 9. Thirdly, JS-X, which is an overall index of perceived stress formed by multiplying the Severity-items with the matching Frequency-items. Results No difference between coaches with high versus moderate or low emotional exhaustion scores was found for the Severity-scale. However, for the Frequency-scale, there was a significantly ( $P = .03$ ) greater mean score observed for the group with high EE ( $M = 3.9$ ,  $SD = 1.6$ ) than for the group with low or moderate EE ( $M = 2.7$ ,  $SD = 1.5$ ). For the JS-X scale, a significant difference ( $P = .04$ ) was also found; the group with high EE displayed a higher overall perceived stress ( $M = 20.0$ ,  $SD = 9.8$ ) than the group with moderate or low EE ( $M = 13.2$ ,  $SD = 8.0$ ). Discussion Our findings indicate that the group of coaches scoring high on emotional exhaustion did not perceive the job stress demands (JS-S) as more stressful than the group with moderate or low scores on EE. However, the significant differences in both the frequency (JS-F) and the index (JS-X) scales show that the groups differ in areas linked to the actual work situation. The group scoring high on EE perceive that they have to deal with stressors linked to job stress to a higher degree than the moderate or low scoring EE-group. The former are either overexposed to these kinds of job stress demands, or they have lower thresholds for how they perceive the stress as measured by the JSS-items. References Kelley, B. ### **IS COACHING EVALUATION ASSOCIATED WITH COLLECTIVE EFFICACY ON UNIVERSITY BASEBALL ATHLETES? - DEVELOPMENT OF COACHING EVALUATION SCALE AND COLLECTIVE EFFICACY SCALE FOR BASEBALL ATHLETES-**

SHIMIZU, Y., MIYAZAKI, M.

*J.F.OBERLIN UNIVERSITY, TOKYO*

Introduction Baseball is the one of the most popular sports in school club activities from elementary to college level in Japan. Prior studies reported that baseball coaching in Japanese schools includes not only instruction of baseball skills and strategies but also social norms, ethics and human relationships. The purpose of this study was to develop Coaching Evaluation Scale for Baseball Manager and Coach (CESBMC) and Collective Efficacy Scale for Baseball Athletic Teams (CESBAT) and to examine the relationship between factors of CESBMC and CESBAT. Methods The subjects of 89 baseball athletes (mean age=19.08, SD=0.83, mean baseball experience=11.33, SD=1.96) in official university baseball team were asked to answer a questionnaire that was composed of socio-demographic questions, 48 coaching evaluation question items developed from our preliminary survey in 2009 and collective efficacy question items edited from Collective Efficacy Scale for Soccer Teams by Kuniyoshi and Shimizu (2009). Exploratory factor analyses and reliability analyses were conducted to develop CESBMC and CESBAT. In order to examine the relationships between CESBMC and CESBAT, multiple regression analyses were conducted. Results The results of exploratory factor analyses identified that CESBMC has 8-factor model with 40 items: "Coaching Policy," "Coaching Attitude," "Skill Instruction," "Original Personality," "Team Leadership," "Team Observation," "Communication Skill," "Counseling Abilities," and CESBAT has 7-factor model with 35 items: "Efficacy for Practice," "Efficacy for Performance," "Efficacy for Social Support," "Efficacy for Goal Achievement," "Efficacy for Cooperation," "Efficacy for Emotional Expression," "Efficacy for Loyalty." Reliability analyses confirmed that each scale had satisfactory Cronbach's alpha coefficient reliabilities from 0.877 to 0.952. The results of multiple regression analyses showed that the sub-scales of CESBMC were significantly positively associated with the sub-scales of CESBAT. Discussion Each of the factors of CESBMC and CESBAT showed statistically satisfied Cronbach's alpha reliabilities. The results of multiple regression analyses indicated that the subjects with higher CESBMC scores were likely to have higher CESBAT scores. Future research using larger sample sizes and longitudinal design is needed to examine effective psychological coaching intervention methods for baseball managers and coaches. ### **THE INFLUENCE OF CROWD NOISE ON JUDGING SPORT**

MYERS, T., BALMER, N.J.

*NEWMAN UNIVERSITY COLLEGE*

THE INFLUENCE OF CROWD NOISE ON JUDGING SPORT Myers, TD 1, Balmer, NJ 2 1: NUC (Birmingham, UK), 2: UCL (London) Introduction Home advantage has been established in a number of sports. Research has found home advantage to be particularly prominent in subjectively judged sports (Balmer, Nevill & Williams, 2001). One plausible agent postulated for the effect on subjective decisions, is crowd noise (e.g. Unkelbach & Memmert, 2010). Crowd noise might influence officials via a number of mechanisms including normative and informational conformity. A major limitation of studies conducted in this area is the use of recorded rather than live crowd noise. In the absence of participants' expectations of a vocal crowd's real response, the possibility of considering normative conformity is reduced considerably. As such, the aim of this study was to examine the influence of the noise from a real crowd on home advantage in judging Muay Thai bouts. Method 17 qualified Muay Thai judges participated, judging 30 Muay Thai bouts in one of two conditions: a crowd noise condition and in no crowd noise condition. The crowd noise condition involved judges experiencing the natural crowd noise, and the no noise condition involved judges wearing noise cancelling headphones and listening to a track of white noise. Each bout was judged by four participants; two in each condition. Multilevel modelling was used to analyse the data using MLwiN. The difference between home and away scores over five rounds was modelled as a normal response variable. This type of data structure can be described as cross-classified and modelled using Markov Chain Monte Carlo methods within MLwiN. Results Crowd noise had a significant impact on judging ( $\chi^2 = 5.17$ ,  $p = 0.023$ ). Using points in favour of the home side as an outcome measure, results showed that exposing judges to crowd noise resulted in a difference of 0.53 points in favour of the home competitor. Discussion The results suggest that crowd noise can result in judges awarding inflated scores to contestants receiving the greater crowd support. The results support previous findings in this area (Nevill, et al., 2002; Unkelbach & Memmert, 2010) but in a more ecologically valid setting. The findings suggest judges may have conformed to the views of the majority, who vocally supported the home favourite. However, the white noise used in the no crowd noise condition may have been a confounding factor. Although the results can be explained by social conformity factors, it is possible that they could have been the result of other factors (visual perceptual errors; the incorrect application of a noise heuristic and or cue salience). It is possible that a combination of all these factors may be responsible for the results found. References Balmer NJ, Nevill AM, Williams A. (2001). *J Sports Sci*, 19, 120-139 Nevill AM, Balmer NJ, Williams M. (2002). *Psychol Sport Exerc*, 3, 261-272 Unkelbach C, Memmert D.(2010). *J. Sport Exerc. Psychol.* 32, 4, 483-498

### **MOTIVES FOR BEING A REFEREE IN FOOTBALL**

JOHANSEN, B.T.

*UNIVERSITY OF AGDER*

MOTIVES FOR BEING A REFEREE IN FOOTBALL (SOCCER) Johansen, B.T., Bjørnstad, J.O. University of Agder, Norway Introduction The study of motivational issues among referees and officials in sport is limited, but nonetheless important in order to provide information about what factors stimulate for becoming and for being a referee in football (Helsen & Bultynck, 2009). One may ask: "Who's the man in black?" And, for what reasons do they choose to be a referee in football? The aim of this study is to investigate different motives for being a referee or refereeing among Norwegian qualified football referees. Methods 44 part-time referees from Agder region in southern part of Norway participated. Totally it was 3 female referees and 41 males mean age of 38.3 (SD = 13). The referees were in a questionnaire asked to report randomly three main reasons or motives for why they become a referee. The data were analyzed using a well specified phenomenological procedure for qualitative research (Marton, 1995). Results were obtained by bracketing, intuiting, and describing the different motives or reasons for being a referee reported and organized into categories of description. The different categories of description that emerged were studied and regrouped by two colleagues. Results 107 (81 %) of a total of 132 different motives or reasons for

being a referee reported were bracket and grouped, and three main categories emerged; fitness motives, 31 % (e.g., physical activity, being in good shape, body appearance), passion motives, 25 % (e.g., simply love football, enjoyment, excitement), social motives, 25 % (e.g., meeting with people, staying in football, competition situation, member of the team). Among the 25 remaining statements (19 %) there were only seven economic related motives reported, seven motives were related to leadership, and seven motives were related to decision making. Discussion The findings reveal that Norwegian part-time referees have a solid practical and educational background, and based on the motives reported, and their modest income from officiating, the money seems not to be an important motivational factor. Moreover, one may claim that Norwegian part-time referees in some extend are motivated by just being part of the football family and playing a vital part of the game, and based on research in this field, there is little or no reason for suggesting that this is not the case for football referees in other parts of the world. One could say that Norwegian part-time referees officiating involvement is more or less pure enthusiastic and it seems that the referees are motivated through satisfaction through physical activity, being a part of the football family, and they love doing it! References Helsen W, Bultynck JB. (2009). *J Sports Sci*, 22, 179-189. Marton F. (1995). *Nord Ped*, 15, 165-180.

## DEALING WITH PAIN: THE COACH'S SUBJECTIVE SENSE OF THE ATHLETE'S PAIN IN HIGH PERFORMANCE TRAINING

DOBŘANSZKY, I., RUETE, H.

PONTIFÍCIA UNIVERSIDADE CATÓLICA DE CAMPINAS

Introduction In our researches into subjectivity and sport, particularly on Iron Man athletes, pain has been shown as part of daily training and competition. This has been a subjective sense indicator in the relationship coach/athlete that is connected to multiple symbolic and emotional processes that characterizes that social environment. Although Iron Man demands high levels of intense physical exertion, pain can be related to psychological issues, with repercussions for the athletes and coach communication and therefore for the sport performance. This study aims to analyze the coach's subjective sense about the athlete's pain. Method The study emphasizes the constructive-interpretative and dialogical character of the knowledge (González Rey's, 2005). Participants: a 15 years old female triathlon athlete, two Iron Man athletes -48 and 36 years old-, and a 39 years old female coach. For the accomplishment of this study the instruments used were: conversational dynamics, term used to emphasize the procedural and open character of the relationships with the participant; complement of sentences, which allowed acquiring information about the production of sense of the individual; and a field diary. Results The analysis of the subjective sense indicators supported by instruments, took us to the construction of the following subjective senses nuclei: i) the influence of the former athlete's subjectivity on hers athlete's subjective sense; ii) the influence of the pain in the production on the athlete and coach's subjective sense. Discussion The meaning of pain for the athlete and for the coach is not the same for each of them. The individual subjective sense of the athletes pain is not related to it, but to how the coach interpretes it. Athletes compare their pain, triggering an unconscious process of competition between them, disputing for the coach's attention and her bond. By touching with care the bruises, the coach conveys her support or not and her feelings related to it. It is important to mention that she is aware of the group's dispute for her attention, and she interpretes this dispute as a recognition of her technical competence. She also does not establish a dialog with the athletes as a group she only does it individually not building a sympathetic feeling among the athletes as a group. The coach and team's subjective configuration is developed on production of the symbolic processes based in competition. The competition between all athletes on individual's subjective sense only decreases when one of the members' achievements stands out in a way that others recognize this result as worthy of special attention of the coach, although they may also experience feelings of jealousy. ## THE BRAZILIAN MEN'S ARTISTIC GYMNASTICS JUDGES' EDUCATION DURING THE 2005-2008 OLYMPIC CYCLE

OLIVEIRA, M.S.1, BORTOLETO, M.A.C.2

1 STATE UNIVERSITY OF SÃO PAULO (SÃO PAULO, BRAZIL); 2 STATE UNIVERSITY OF CAMPINAS (CAMPINAS, BRAZIL)

Introduction Although there are rules which brought reliability and objectivity to AG scoring system, the performance of an athlete is evaluated according to the judge's individual perception (STE-MARIE, 1996). In order to minimize the inherent subjectivity in the AG evaluation, the judges need a proper education program along with a constant updating and experience in competitions (BORRMANN, 1980). This abstract aims to discuss the Brazilian men's artistic gymnastic judges' education during the 2005-2008 Olympic Cycle. Methods We conducted semi-structured interviews with nine AG experts who work directly with the high level of Brazilian MAG. For data treatment we used the Content Analysis (BARDIN, 2008). Results In recent years, with better organization of AG in Brazil, we notice an expressive improvement in the quality of the judges, especially among those with the national and international brevets. The experts said that the better format of the regional and national courses and the implementation of a more rigorous assessment to obtain the brevets helped to improve the Brazilian judges qualification. However, this qualitative improvement was not reflected quantitatively in the country. There was a lack of judges with national brevet during the 2005-2008 Olympic cycle due the realization of only one national course. The study also found out that many states didn't organize regional courses which contribute, significantly, to the development problems of MAG in Brazil. The experts also reported that the scarcity of incentive and the insignificant financial support contributed to the lower number of judges in MAG. Conclusion There was a qualitative improvement in Brazilian MAG judges' education but, unfortunately, this not reflected quantitatively due to the few number of courses realized in the national and regional levels. The lack of recognition and support to the judges' carrier are the main aspects that contribute to the reduced number of judges in action in Brazil. We would like to emphasize the importance of the judge education because before acting as a judge, he is an educator who through his actions provides directions to the coaches and athletes supporting the development of AG. ## COMPETENCES OF FLEMISH BASKETBALL COACHES

CAPLIN, A., ZINZEN, E.

VRIJE UNIVERSITEIT BRUSSEL

Introduction The European Qualification Framework (EQF) is the basis for many countries of the world to set up a National Framework. It consists of competences of all jobs, classified in numbered levels (OECD, 2005). This study aims to determine the competences of basketball coaches and create a framework in which the coaches work, to improve the quality of coaches and coaching programs. Once the educational programs comply completely with the EQF norms, coaches can be recognized internationally (Scatoli, 2009). Method The Delphi Method was used to personally interview Flemish qualified basketball experts (in different rounds) to ensure that all coaching

views/opinions were enclosed and that the results are borne by everyone. After two personal contacts, the experts had a meeting to discuss the specific core tasks with their associated knowledge, skills and attitudes and try to reach a consensus (Dalkey, 1969). Then, in the final round, the competences were composed (using COMET, 2003) and confirmed by all experts. Results A strict framework was built, combining the coach levels versus the target the coach is trained for. The basketball coach EQF 5 and 6 has five main tasks, including following refresher courses and self-assessment, training, recruit and coordinate, coaching and supporting/guiding. There were seven competences formed, namely: to communicate, to give feedback, to provide individual coaching, to act as a responsible teacher and pedagogical practitioner, to plan, to work in a team and to act with a purposeful vision. Due to the fact that coaches work in level-dependent contexts, the contents of the competences differ. The experts decided unanimously that a higher level (EQF 7) should be established, based on the existing FIBA concept. Discussion and conclusion The results have been synthesised into competency cards for basketball coaches 5 and 6 and refer to the EQF. To be able to make international comparisons it is necessary that other countries incorporate their teaching/coaching programs into the EQF. ## REPRESENTATION OF COMPETENCE IN COACHES: A STUDY WITH ELITE COACHES OF FOOTBALL AND GYMNASTICS.

PEREIRA, A., SOUSA, T., BATISTA, P., MESQUITA, I.

*FACULTY OF SPORT, CIFI2D*

Introduction Despite multiple efforts for clarification around the concept of competence, several areas of contamination still persist, resulting not only in an indiscriminate use of the word competence in common sense, but also in the not so cautious, or even arbitrary use, which is made on the scientific discourse (Parente, 2003; Weinert, 1999). According to Sandberg (2000), to describe competence requires not just their attributes but as a starting point of the workers conceptions. Through this study we tried to capture the coaches' understanding of competence according to the sport they coach (football and gymnastics). Methods Eight elite coaches were interviewed (4 from football and 4 from Gymnastics). The procedures of content analysis were used to data analyze with the support of Nvivo7. The generality of the categories were defined a priori based on the professional competence model (Cheetham & Chivers, 1998) and some of them were defined a posteriori. Results In general the results show that the nuclear component of competence most valued by the coaches were the knowledge/cognitive and the least the values/ethical. The functional component and the personal/behavioural were found in the middle. In relation to the competence representation of the football coaches the categories more valued were the knowledge/cognitive and the personal/behavioural competence. Whereas, for the gymnastics coaches the others factors (e.g. personality, heteroperception of competence, results and context) were the most relevant components in their representation of competence. Discussion The notions coaches held of competence are different in relation to the kind of sport, nevertheless the two groups give more importance to the knowledge component of competence. Therefore, in the study of competence it is fundamental include the actors voice, because the context are distinguished and the needs are also different. Like Sandberg (2000) say there is an intimate relationship between the work, the worker and the context. References Cheetham, G., & Chivers, G. (1998). ## ROLE AND IMPORTANCE OF FOOTBALL REFEREES IN WRITTEN AND VISUAL MEDIA

GUNDUZ, N.

*ANKARA UNIVERSITY GRADUATE SCHOOL OF HEALTH SCIENCE*

Role and Importance of Football Referees in Written and Visual Media Cuhacıoğlu, A.E., Gündüz ,N., Abstract Introduction The professions like football, which draw interest worldwide as well as Turkey, have widespread media coverage and are influenced by media. Therefore, it is indispensable that written and visual media influences football referees. Hence, the appropriate use of media for the improvement of football and its resulting positive effects on football are of great importance. This survey study aimed to detect the role and importance of football referees in the written and visual media. Methods Qualitative techniques were used in data collection process. Study sampling was composed of 100 media employees. Study questionnaire was administered to visual media employees during the visits paid to the national 11 television channels and to written media employees during the visits paid to Turkish Sports Writers' Association and to the 6 national newspapers. Among the study sampling, 12 participants voluntarily answered the interview questions. Questionnaire items were developed on the basis of the studies and resources on this issue as well as expert opinions. Validity and reliability of the questionnaire was tested on 20 participants and, Alpha reliability coefficient of the questionnaire was calculated to be .87. Study questionnaire is composed of 3 parts. First part includes items on personal information of the participants; the second part includes a 12-item Likert-type questionnaire about the role and importance of referees in the written and visual media; and the third part presents 7 interview questions. Arithmetic means and percentage and frequency distribution of the study data were calculated by using SPSS package programme. Moreover, the study data were subjected to t-test and variance analysis. Results According to study results, news on football referees is closely monitored by the written and visual media employees. These people think that football referees have a good media image and that referees are paid required attention by the media. In addition, written and visual media employees believe that criticisms and performance evaluations targeted at referees should be more tolerant. Discussion Although it is stated that those working in written and visual media should not be influenced by the news regarding referees published/broadcasted following an event (Goral, 2003), it was found that there exists a group being influenced by the news published. The research results showed that it is not required to be a former referee or football player in order to be a football critic but rather media should follow ethical principles (Uzun, 2004). ## WORKING WITH BRAZILIANS: SUPPORTING A FOOTBALL TEAM FROM CONCEPTS DERIVED FROM A COMPLEX-CONSTRUCTIVIST PARADIGM

BUCHANAN, N.

UNIVERSITY OF THE WEST OF SCOTLAND

Buchanan, N.I, Ollis, S.I 1: University of the West of Scotland (Hamilton, Scotland) Introduction: There is considerable desire to understand how we develop, instruct and generate peak performance in various sporting domains. This work reports on a complex-constructivist paradigm of applied multi-disciplinary support – to organisation, team and individuals. The model had already been adopted on the creation of a suitable talent development environment and peak performance capability with the Scottish small-bore shooting team (Ollis & Sproule, 2007). However, could it be replicated in an alternative sporting domain? The aim of this report was to analyse the benefits of a complex constructivist notion of expertise in the support of a football team....not merely Brazilians, but the more infamous Blue Brazil. Methods: The report looks at the complex-constructivist worldview of applied support through a case study which shifted from applied to action research to ethnographic design over a prolonged period of three years. The final phase of the work, within which the work resides as research, focuses on an ethnography of how the club, coaching staff and players functioned. Results: Like the previous research study on small-bore shooting, the findings suggested the ability to adapt and regulate to a challenging, complex and real-world event such as playing football professionally is dynamic, iterative and multi-faceted. Thus, the focus on enhancing adaptive capability across the full 'complex-ecological' model of what is a football club, and its synergetic properties were recorded. The ability to evolve the club, develop talent, coach and peak perform were identified as a trans-disciplinary model which accepted the running of a football club and real world coaching as messy, uncertain and paradoxical. Those who were offering applied support and the primary researcher were fortunate enough to partake in a football club which had a 'dream' three seasons and performing beyond itself. Discussion: The applied report and subsequent ethnography suggest that there is scope to understand the development of talent, the development of a team, and the development of a club from more non-linear and complexity science based design of learning, coaching and development. The work suggests that the trans-disciplinary nature of the sporting institution may serve for the ability to peak perform more than the addition of contributions alone. Thus talent development, sports management, coaching and the peak performance may be served better through more systemic and trans-disciplinary concepts and tools. The model served as the platform for the primary authors PhD investigating the principle of 'deliberate experience'. References: Ollis S, Sproule J. (2007). Constructivist coaching and expertise development as action research. *International Journal of Sport Science and Coaching*, 2(1), 1-14.

## HEURISTIC REASONING AND SPORT OBSERVERS: ON THE INFLUENCE OF EXAMPLE-AVAILABILITY ON AD-HOC FREQUENCY JUDGMENTS

MILLER, P., ROWE, L., CRONIN, C.

UNIVERSITY OF CUMBRIA

Introduction A corpus of social cognitive research has documented that when performing everyday reasoning tasks 'on-the-fly', individuals rarely (if ever) attempt a comprehensive examination of all relevant resources from social memory. Instead, metacognitive strategies – judgemental heuristics – are employed to expedite these tasks. The most robustly demonstrated 'heuristic' is the availability heuristic (Tversky and Kahneman 1973; 1974). This heuristic, describes the manner in which estimations of frequency or probability tend to be induced from the information most cognitively salient to an individual, i.e. task-relevant examples that can be easily recalled have a disproportionately high frequency/probability estimation. Incorporating 'fame availability' (Mekelvie 1997) the empirical focus of the study was on the 'snap judgements' made by observers of sport images. Methods Subjects (n=141) were shown a variety (50) of images of football, tennis, golf, netball, running athletes in action from the public domain. Images were grouped and divided into celebrity (high profile professional athletes in football, tennis, golf) and non-celebrity (low profile recreation athletes participating in netball and running). In a time-pressured environment, participants estimated the frequency of images observed for each sport. The scores of the five sports, consisting the two groups were averaged to provide a single participant value for celebrity and non-celebrity sports. Results Normality of data was checked using Kolmogorov-Smirnoff and subsequently confirmed. A paired t-test was used to examine for difference between the two groups. Frequency scores for celebrity sports ( $12.0 \pm 3.3$  times) were significantly more ( $t(136) = 7.394$ ,  $P = 0.001$ ) than non-celebrity sports ( $9.9 \pm 3.3$  times). Discussion Results of this initial study indicated the influence of the availability heuristic on the frequency estimations of the sport spectators. Heuristics are an adaptive tool (Gigerenzer, 2006) which have the potential to produce effective on-the-spot judgements. However these results suggests that significant distortions of frequency may arise through the influence of heuristics at this peripheral site of sport involvement. Given the contextual ambiguity influencing those centrally involved in sport (coaching, refereeing, scouting) and the importance of decision-making under time constraints, further research on the influence of heuristics in the decision making of practitioners is recommended. ## AN ETHNOGRAPHIC STUDY OF PSYCHOSOCIAL DYNAMICS IN ELITE SPORT

LEE, S.

UWE HARTUPURY

Elite sport is firmly established as a business enterprise with personnel now operating within sport organisations that are similar in structure to commerce organisations. This evolution of the sports industry has imposed numerous demands on the key stakeholders responsible for performance and as such the requirement for effective organisational processes is imperative for developing both team and individual flourishing. Research emanating from the management literature would suggest that many key determinants for success stem from environmental dynamics and how effectively organisations operate. Conversely, sport psychology and organisational psychol-

ogy literature indicates that ineffective sport organisations compromise athletic performance. However, despite these lines of inquiry, progress has been slow in attempting to establish the specific dynamics that determine organisational effectiveness within sport, particularly from the psychosocial perspective. Therefore, the purpose of this study was to identify psychosocial dynamics of effectiveness within an elite rugby union team, playing in the English Premier League. Following procedures used by Faulkner and Sparkes (1999), ethnographic methods were employed to establish the common themes that impact on effectiveness. Findings indicated psychosocial dimensions of effectiveness associated with: communication and relationships, atmosphere and culture (open environment conducive to relationship building); socio-emotional skills (emotional and social intelligence); social norms and behaviour expectations; and goal orientation (shared vision of being achievement-orientated). Results suggest that interpersonal dynamics contribute to organisational flourishing in such a way that has the potential to impact on both team and individual performance. As such, practitioners must be aware that personnel, the internal processes that they share in, and their socio-emotional skills are imperative to developing and sustaining environments where high performance can be achieved. This investigation has highlighted the importance of understanding how sports organisations are able to flourish, paving the way for further enquiry. Faulkner, G. & Sparkes, A. (1999). Exercise as therapy for schizophrenia: An ethnographic study. *Journal of Sport and Exercise Psychology*, 21, 52-69.

### COGNITIVE APPRAISAL JUDGMENTS AS DETERMINANTS OF THE PRECOMPETITIVE EMOTIONAL RESPONSE

WOLF, S., EYS, M., KLEINERT, J.

GERMAN SPORT UNIVERSITY

COGNITIVE APPRAISAL JUDGMENTS AS DETERMINANTS OF THE PRECOMPETITIVE EMOTIONAL RESPONSE Wolf, S.1,2, Eys, M.2, Kleinert, J.1 1:GSU (Cologne, Germany), 2:WLU (Waterloo, Canada) Introduction One critical aspect of successful sports performance is the athlete's precompetitive emotional state (Prapavessis and Grove, 1991). According to cognitive-motivational-relational theory (Izard, 2010), each discrete emotion is elicited by a unique pattern of cognitive appraisal. However, with respect to precompetitive emotions, the specific appraisals that distinguish each emotional state have yet to be established. Hence, the aim of the present study was to uncover differences in cognitive appraisal between athletes experiencing anxiety compared to those experiencing positive anticipation prior to a competition. Methods A sample of 353 Canadian university and college athletes (46% female, M=20.28 yrs.) from the sports of basketball, ice hockey, and volleyball completed the Directional Modification (DM; Jones and Swain, 1992) of the Competitive State Anxiety Inventory-2 (Martens et al., 1990) approximately 80 minutes prior to a regular in-season game. Athletes with somatic/cognitive DM values  $\leq M-1SD$  were defined as anxious, whereas athletes with values  $\geq M+1SD$  were defined as experiencing anticipation. Precompetitive appraisal was assessed by 7 items targeting goal-relevance, goal-congruency, blame/credit, coping potential, and future expectations. Results Two MANOVA revealed differences between anxious athletes as compared to those experiencing anticipation regarding their overall cognitive appraisal: somatic,  $F(7,89)=3.06$ ,  $p=.006$ ,  $\eta^2=.19$ ; cognitive,  $F(7,87)=1.80$ ,  $p=.097$ ,  $\eta^2=.13$ . For somatic symptoms, anxious athletes associated the upcoming competition with significantly less desirability ( $\eta^2=.09$ ), responsibility ( $\eta^2=.05$ ), coping resources ( $\eta^2=.08$ ), and success-expectations ( $\eta^2=.07$ ). For cognitive symptoms, anxious athletes reported significantly less desirability ( $\eta^2=.05$ ), control ( $\eta^2=.05$ ), and success-expectations ( $\eta^2=.06$ ). We found no differences regarding goal-relevance. Discussion Consistent with theoretical assumptions and previous findings (Uphill and Jones, 2007), cognitive appraisal emerged as an important factor discriminating between the similar yet distinct precompetitive emotional states of anxiety and anticipation. Specifically, perceptions of the situation's general favorability and estimated options/prospects of coping appeared to play an important role and provide potential targets for applied interventions. Further investigations are needed, however, to generalize these findings to other types of sports or performance levels. References Prapavessis, H, Grove JR (1991). *Sport Psychol*, 5, 223-234. ### AFFECT AND PERFORMANCE IN A BADMINTON TOURNAMENT: AN ANALYSIS OF CHANGES WITHIN AND BETWEEN MATCHES.

RHODEN, C., WEST, J.

UNIVERSITY OF WORCESTER

Introduction Positive affect has been shown to be related to performance in climbing (Sanchez et al., 2010) and wrestling (Treasure et al., 1996) however both studies utilise only pre-performance affect. Affect fluctuated within a golf tournament (Gaudreau et al., 2002) although retrospective methods of assessing affect during the tournament were used. The aim of the current research was to utilise within activity methods to analyse affect and performance both between and within matches during a badminton tournament. Methods Sixteen male and female county badminton players aged  $25 \pm 7.44$  yrs participated in a competitive mixed doubles round robin tournament comprising 2 groups of 4. Each pair played in 3 group matches and 1 further match to determine their final ranking within the 8 pairs. Players completed the PANAS (Watson et al., 1988) to measure positive affect (PA) and negative affect (NA) 5 minutes before and after each match. Between match games players rated their PA and NA on the Worcester Affect Scale ranging from 1 'not at all' to 10 'very much' (Rhoden & West, in press). Games and match scores were recorded throughout. Results Fluctuations in PA and NA were observed throughout the tournament. Players within the top 4 final ranked pairs maintained moderate to high levels of PA across matches (range 6 to 9). Positive affect for players within the bottom 4 final ranked pairs decreased significantly from the beginning to the end of the tournament (Pre match 1 PA median=28; post match 4 PA median=14;  $z=-2.39$ ,  $p=0.017$ ). Despite similar levels of PA and NA pre-tournament, final PA scores were significantly different between the top 4 (PA median=30) and bottom 4 ranked pairs (PA median=14;  $z=-2.83$ ,  $p=0.005$ ). Discussion A unique feature of this research was the within match assessment of affect and performance. PA and NA fluctuated over the course of the badminton tournament thus extending the findings of Sanchez et al. (2010) and Gaudreau et al. (2002) and stresses the importance of affect-performance research. More successful players; ranked higher in the tournament overall, exhibited higher levels of PA characterised by feelings of confidence, determination and alertness (Watson, 2000) which corresponded to better mixed doubles performance and are discussed within the context of goal expectation and achievement. ## COMPRASSION OF COMMUNICATION SKILLS LEVEL OF TEAM AND INDIVIDUAL SPORTS ELITE ATHLETES

OZDEMIR SAHIN, F., GEZER, E.D., ASLAN, C.S.

ANKARA UNIVERSITY

COMPRASSION OF COMMUNICATION SKILLS LEVEL OF TEAM AND INDIVIDUAL SPORTS ELITE ATHLETES Ozdemir Sahin, F. N.1, Gezer E.D.1, Aslan C.S.1 1: Ankara University PES (Ankara, Turkey) Introduction Communication can be defined as transactional process that involves an exchange of ideas, information, feeling, attitudes beliefs and impression (Sen, 2008). Good and effective communication leads personal effectiveness, help to network with other people, create better interpersonal relations, and increase listening abilities and influence motivation to enhanced performance. Communications skills (CS) are one of the important components of sports for success especially in team sports. Therefore the purpose of this study is to compare CS of individual athletes (IA) and team sport players (TSP). Methods 131 elite athletes (80 TSP, 51 IA ) participate in this study as voluntary. Communication Skills Evaluation Scale (CSES) and its validity (.86) and reliability (.78) was established by Korkut in 1996 was used in this study. This scale consists of 25 item and 5 point Likert scale. Obtained data were analyzed by SPSS (ver. 16). Mann-Whitney U was used to compare groups and  $\alpha$  was set as 0,05. Results Mean age of IA is  $21,16 \pm 6,55$  and TSP is  $26,96 \pm 3,74$  years. CS score of team sports group indicated that  $101.58 \pm 9.08$  and individual athletes group was  $98,82 \pm 11,90$ . There is no statistically significant differences between TSP and IA ( $p=0,198$ ;  $p>0,05$ ). Discussion In this study, each group scored high in CSES. Although many studies indicated differences between athletes and non-athletes CS, there are limited studies about differences between athletes themselves. Tepekoylu et al (2009) and Yilmaz & Cimen (2008) found there were no significant differences between athletes at the point of CS. When evaluating athletes in themselves in this study also there is no significant difference between TSP and IA's communication skills. In conclusion; when being athlete improves CS, it may claim that being a TSP or IA not effect on CS level. References Korkut F. (1996). ## AN INVESTIGATION INTO THE EMOTIONAL INTELLIGENCE AND MOOD STATES IN UNIVERSITY STUDENTS

SOOS, I., LANE, A.M., TATTERS, A., KARSAI, I., HAMAR, P.

UNIVERSITY OF SUNDERLAND

Introduction Evidence shows that measures of self-report emotional intelligence and mood states are important predictors of performance in a range of contexts including academic and sports settings (Lane et al., 2010). Despite encouraging evidence on the utility of using emotional intelligence to assess athletes, we argue that replication of findings to demonstrate the consistency of relationships could provide a solid footing for developing intervention designed to improved performance via enhancing emotional intelligence. The present study investigated the relationship between mood and emotional intelligence in relation to successful and unsuccessful academic and sports performance among university students attending sports-related degree courses, a design that replicates the one followed by Lane et al. Methods Sports students ( $n=134$ , mean age=20.0 years,  $s=2.3$ ; male=85, female=49) completed the 32-item Brunel Mood Scales (BRUMS, Terry et al., 1999) based on retrospective accounts of mood in relation to successful and unsuccessful academic and sports performance. Emotional Intelligence (EI) was measured by using the 10-item Brief Emotional Intelligence Scale (BEIS, Davies et al., 2010). Results A  $2 \times 2$  (EI x performance) repeated measures MANOVA was conducted to test for differences in mood states before successful and unsuccessful sports and academic performance. The two-way interaction was significant (Pillai's Trace= .254,  $F_{1,600}=2.442$ ,  $p=.003$ ). Univariate tests showed significant differences: High EI was associated with low anger ( $F=6.455$ ,  $p=.012$ ), depression ( $F=4.305$ ,  $p=.04$ ), fatigue ( $F=5.405$ ,  $p=.011$ ) and confusion ( $F=4.707$ ,  $p=.032$ ) before successful sport performance; low EI was associated with less fatigue before poor academic performance ( $F=6.145$ ,  $p=.014$ ). Conclusions Our study lends support to the notion that students with high level of emotional intelligence report higher scores of pre-competition mood in both sport and exam situations. We suggest future work should investigate the effects of intervention strategies to design to enhance emotional intelligence on pre-competition mood and performance. References Davies, K., Lane, A. ## PSYCHOMETRIC ISSUES IN ORGANIZATIONAL STRESSOR RESEARCH: A REVIEW AND IMPLICATIONS FOR SPORT PSYCHOLOGY

ARNOLD, R.S., FLETCHER, D.

LOUGHBOROUGH UNIVERSITY

Sport performers seeking to attain peak performances must ensure that they are in an optimum physical and psychological state when they compete. This is a challenging task since the organizational and social environment surrounding athletes imposes numerous demands on them, many of which can potentially elicit a number of undesirable consequences for them and disrupt their preparations for competition (Gould, Guinan, Greenleaf, Mudbery, & Peterson, 1999). It is, therefore, imperative that psychologists better understand the demands that athletes encounter via their exploration and assessment. However, although researchers have identified a wide range of organizational stressors experienced by performers (see, for a review, Arnold & Fletcher, 2011), they have yet to develop a measure or indicator to assess these demands. In contrast, scholars working in other sub disciplines of psychology have designed instruments that measure organizational-related stressors in different contexts (see, for a review, Rick, Briner, Daniels, Perryman, & Guppy, 2001). The development and use of these measures have the potential to inform the advancement of stress research in sport. Therefore, the purpose of this paper is to review psychometric issues in organizational stressor research and to discuss the implications for sport psychology. The review is divided into four main areas: conceptual and theoretical issues (e.g., defining organizational stress-related concepts, underpinning measures with a theory, and differentiating between the separate components of the overall stress process), item development issues (e.g., distinguishing between different types of stressors, selecting the number of items to develop, and establishing the generality versus specificity of the wording), measurement and scoring issues (e.g., measuring stressors subjectively or objectively, adopting a triangulation strategy, measuring dimensions over demand, and choosing the most appropriate response format and scor-

ing method), and analytical and statistical issues (e.g., sample selection, factor analysis, and measuring and controlling for confounding variables). References Arnold, R. S., & Fletcher, D. (2011). ### **CHEATING IN FOOTBALL; TEAM CULTURE, PLAYER BEHAVIOUR OR A QUESTION OF CIRCUMSTANCE?**

STRIDE, C.B., PATTERSON, M., THOMAS, F.E.

UNIVERSITY OF SHEFFIELD

CHEATING IN FOOTBALL; TEAM CULTURE, PLAYER BEHAVIOUR OR QUESTION OF CIRCUMSTANCE? Stride, C.B. 1, Patterson, M. 1, Thomas, F.E. 2 1: Inst. Work Psych., University of Sheffield; 2:University of Cambridge Introduction Cashmore (2000) describes cheating as "to act fraudulently, to deceive, swindle, or flout rules designed to maintain conditions of fairness". We examined cheating, categorised in a sporting scenario by Loland (2005), in the context of association football, extending his typology by grouping 17 offences into 4 types: Simulation, Classic Cheating, Professional Fouls and Calculated Dissent. We investigated whether and why the incidence of these types differed between players, teams and matches. Hypotheses We hypothesised that variation in cheating would exist between players, teams and matches. Between player variation would exist due to differences in both mental and physical drivers, such as moral functioning, motivation, ability, experience and playing role. Between match variation would be due to differences in importance, closeness, and law enforcement. Between team variation would be due to varying ability, expectation, styles of play, 'team climate', and national culture (e.g. dimensions of Individualism, Masculinity, Power-distance, Uncertainty Avoidance; Hofstede, 2003). Method We collected data from the 2010 Football World Cup (WC2010). Two coders watched every match, recording each cheating incident they identified. Data was also collected for players (e.g. experience, position), teams (ability, manager's background, Hofstede cultural dimension scores), and matches (importance, result, referee). For each type of cheating, multilevel generalised linear models were used to partition variation in the number of cheating events by player, team, and match, and test the effects of player, team and match variables in explaining this variation. Results 412 cheating incidents were recorded, primarily Professional Fouls (275) and Simulation (83). For Professional Fouls, variation was found between matches and between players. This was predicted by playing position (defenders commit more), experience (players with more caps commit less) and importance of match. For Simulation, variation was found between players and between teams. This was predicted by playing position (forwards commit more) and cultural dimensions (countries with high Power Distance and Uncertainty Avoidance commit more), the latter mirroring Franke & Nadler's (2008) findings within organisations. ### **SPORT CAREER TRANSITION: SOME ASPECTS OF THE DIFFICULTIES FACED BY A FORMER ATHLETE IN EMBRACING A NEW ROLE AS A COACH**

DOBŘÁNSZKY, I., RUETE, H., REY, F.

PONTIFÍCIA UNIVERSIDADE CATÓLICA DE CAMPINAS

Dobránszky, I. 1; Ruete, H. Gonzalez Rey, F. 2 1PUC-Campinas (Campinas, Brazil); 2Universidade de Brasília Introduction Although sport organizations and sport managers in Brazil do not usually pay attention to this subject, to sport psychologists it has been otherwise, mainly because a significant part of these former athletes become coaches or school teachers. One of the major problems caused by a poorly planned career transition is the change of the role from athlete to coach (Lavallee, Wylleman, 2000; Stambulova, Stephan, Jäphag, 2007). The main goal of this study is to analyze the subjective sense of the female former athlete on the athletes' subjectivity. Method Eight international and national tri-athletes and a female coach participated in the study. The coach ended her career as a tri-athlete two years before this research, and during it she already worked as triathlon coach to increase her earnings. The method qualitative is based on epistemological studies developed by the psychologist Gonzalez Rey (1997), and emphasizes the constructive-interpretative and dialogical character of the knowledge. The instruments used were: conversational dynamics, term used to emphasize the procedural and open character of the relationships with the participant; complement of sentences, which allowed acquiring information about the production of sense of the individual; and a field diary. Results Our analysis, took us to the construction of the following subjective senses nuclei: i) the influence of the former athlete's subjectivity on her athlete's subjective sense; ii) the difficulty in the moving from the athlete's subjectivity sense to the coach's subjectivity sense. Discussion In Brazil, most athletes cannot dedicate themselves exclusively to their sports career as long as they usually have to work as coach or in another activity to support themselves. Usually they cannot achieve their maximum potential consequently they face frustration or other problems during their sport career transition having difficulties embracing the new role as a coach. The way that athlete faces the difficulties in his sporting life, depends on the subjective's sense that sport has for him and not of his physical, tactical and technique. There are different difficulty levels, which are singular and pass through processes of individual and group subjectivity, and is subject to change according to the production process of subjective senses. ### **RELATIONSHIP BETWEEN IMPLICIT ABILITY BELIEFS, PERCEIVED COMPETENCE AND AMOTIVATION: A STUDY BY VALLERAND'S HIERARCHICAL MODEL**

JUAN-RECIO, C., LÓPEZ, A., MORENO, J.A.

UNIVERSIDAD MIGUEL HERNANDEZ DE ELCHE

RELATIONSHIP BETWEEN IMPLICIT ABILITY BELIEFS, PERCEIVED COMPETENCE AND AMOTIVATION: A STUDY BY VALLERAND'S HIERARCHICAL MODEL Juan-Recio, C., López, A., Moreno, JA. Sports Research Centre, Miguel Hernandez University of Elche, Alicante, Spain. Introduction Using self-determination theory (Deci and Ryan, 1985, 2000) and the hierarchical model of intrinsic and extrinsic motivation (Vallerand, 2001), the aim of this study was to test a theoretical model, relating ability beliefs with perceived competence and each of the dimensions

of amotivation. Since the Amotivation Inventory-Physical Education had not been validated to the Spanish context, psychometric properties were analyzed too. Methods Five hundred and two adolescent students in physical education (252 men and 250 women; mean age:  $14.78 \pm 1.72$  years) volunteered to take part in this study. Instruments -Conceptions of the Nature of Athletics Ability Questionnaire-2. A Spanish version (González-Cutre et al. 2007) of the Conceptions of the Nature of Ability Athletics Questionnaire-2 created by Biddle et al. (2003) was used. -The competence factor of Psychological Needs Satisfaction Scale by Wilson et al. (2006). -Amotivation Inventory-Physical Education (AI-PE). It was adapted and translated from Shen et al. (2010). Results Psychometric properties of AI-PE were analyzed using confirmatory factor analysis, supporting that the reasons why students are not motivated in physical education can be grouped into four dimensions: ability beliefs, characteristics of the task, task value and effort beliefs, showing appropriate validity and reliability. The results of structural equation model indicated that the incremental ability belief in sports positively predicted perceived competence ( $B = .30$ ) and this, in turn, negatively predicted the amotivation ( $B = -.63$ ), explaining the 40% of its variance. Discussion This model can help teachers and trainers to understand better the nature of amotivation and thus facilitate the development of motivational strategies to prevent the abandonment of physical activity in adolescents. These should be aimed to develop incremental ability beliefs, and to promote the perceived competence of students in physical education classes. #### ONLINE MODELLING OF THE CYCLIST'S HEART RATE RESPONSE TO POWER OUTPUT.

LEFEVER, J., BERCKMANS, D., AERTS, J.M.

KATHOLIEKE UNIVERSITEIT LEUVEN

**INTRODUCTION:** Controlling the exercise intensity is important during cycling training to avoid overtraining. Power output can be used as the most direct indicator of exercise intensity (Jeukendrup et al., 1998). Nonetheless, heart rate is more often used as an indicator for exercise intensity and to calculate heart rate zones for the training. These heart rate zones are based on tests on a population level, so they neglect the fact that cyclists are complex, individual, time varying and dynamic systems (CITD-systems) (Quanten et al., 2006). This means that, among other things, the heart rate response to a certain training intensity will vary in time for an individual cyclist. Furthermore, it is likely that the heart rate response could give information about the real-time physical status of the cyclist. The aim of this research is to make a step forward in the development of more individual training sessions for cyclists by making use of engineering, monitoring and control theory. More specifically, the objective is to investigate if we can model the individual heart rate response to power output in real-time. **METHODS:** Three professional male road cyclists and one professional male triathlete ( $24 \pm 4$  years;  $72.3 \pm 4.3$  kg;  $184.0 \pm 4.3$  cm) participated in this study. Ninety-six datasets were collected at random from the participants training and race sessions over the last three years. Those datasets were collected on the road as well as on the track. Two different compact, dynamic and data-based model structures were used to model and simulate the individual heart rate response to power output. The first model structure was the ARX model structure and the second one was the OE model structure (Ljung, 1987). These model structures were calculated recursively and in real-time to model the changing heart rate response to power output. **RESULTS:** The average RT2 between the measured and simulated heart rates with the ARX and OE model structures were 0.86 (std = 0.15) and 0.89 (std = 0.13) respectively. The time constants of the models varied between 2 and 100 seconds. These time constants were consistent with time constants found in literature (in average  $42 \pm 11$  sec). **CONCLUSIONS:** Compact dynamic model structures make it possible to model the cyclist's individual heart rate response to power output in real-time during the training. The acquired information can later be used to adapt and optimise the training for that specific cyclist. **REFERENCES:** Jeukendrup, A.E. & Van Diemen, A. (1998). #### A FLEXIBLE AND EASY-TO-USE WIRELESS SENSOR NETWORK FOR ONLINE MONITORING OF PHYSIOLOGICAL AND BIOMECHANICAL DATA OF MULTIPLE ATHLETES EXEMPLARILY APPLIED IN INDOOR SPINNING

JAITNER, T.I, WEHN, N.2, WILLE, S.2

UNIVERSITY OF KAISERSLAUTERN

**Introduction:** Online monitoring and feedback of objective performance data has been widely proven to substantially enhance the quality of training. Especially for individual sports such as cycling or running highly specialized commercial systems are available. Only few systems support team sports (e.g. LPM, Abatec Electronic AG). To fill this gap, a flexible, compact and easy-to-use wireless sensor network platform named AmiCA has been developed interdisciplinary and customized for online monitoring of physiological and biomechanical parameters of multiple athletes (Wille et al., 2010). It supports the integration of various types of sensors and therefore can easily be adapted to the varying requirements of different types of team sports or group training. A first prototypical application was realized in Spinning. **Methods:** A wireless sensor network (WSN) was established supporting up to 20 wireless nodes mounted on a Spinning bike with integrated sensors for heart rate and cadence measurement. A central gateway node connected to a PC collected data from each node three times per second. Raw data were stored, preprocessed and resultant heart rate and cadence values were presented online on an external display. A baud rate of 38.4kbaud ensured a highly reliable communication between the nodes up to 280m line-of-sight, which is quite sufficient for indoor training. **Results and discussion:** The flexible design of the AmiCA platform and the software framework enabled a development within only two weeks. The WSN was tested during a 12 week Spinning experiment consisting of three training units a week (45 minutes each). Heart rate and cadence data of up to 17 participants were collected and monitored simultaneously during 15 training units. During the whole experiment data communication were highly reliable. Trainers were able to use the nodes

without previous knowledge. As soon as two nodes were activated the WSN worked autonomously. Later activated nodes were automatically reintegrated into the network. The measurement results exceeded our expectations, a clearly improvement of the athletics was traceable. Outlook: The WSN platform allows an easily integration of additional sensors for pedal forces, e.g., and can therefore expanded for different settings such as group training in cycling. At a higher baud rate sensor data of more than 20 participants could be monitored simultaneously. References: Wille, S., Wehn, N., Martinovic, I., Kunz, S., and Goehner, P. ## THE CONCURRENT VALIDATION OF THE FACTOR STRUCTURE OF WOMEN'S HEPTATHLON

HEAZLEWOOD, I.

CHARLES DARWIN UNIVERSITY

**Introduction** The women's heptathlon is an Olympic event, which consists of seven events and conducted over two days of competition. The order of events day 1, 100m hurdles, high jump, shot put and 200m; and day 2, long jump, javelin and 800m. Heazlewood (2008) indicated the factor structure of the heptathlon, using IAAF 2006 data was a three factor model, where 110m hurdles, 200m, high jump and long jump loaded with factor 1, shot put and javelin loaded with factor 2 and 800m on factor 3. The aim of the research was to evaluate if the factor structure in the 2006 data would be replicated with 2010 IAAF heptathlon data. If the interrelationships between the seven events are relatively invariant over time, the factor structure should be replicated across different athletic seasons. As well, the information has implications for heptathlon training based on the factor structure. **Methods** The data consisted of 2010 IAAF ranked heptathletes (n=173) based on points scored in the heptathlon and performances in the seven events to the closest 0.01s for track and 0.01m for field events. Different factor methods of maximum likelihood, principle axis factoring and principle component analysis were applied using PASW Statistics 18 software (SPSS Inc., 2007). The result that generated the most interpretable and parsimonious factor solution was selected to represent the factor structure of the 2010 data and then compared to the factor structure of the 2006 data. **Results** The most interpretable factor structure using 2010 data was principle component analysis, using varimax rotation with Kaiser normalization and an orthogonal structure. This analysis generated a four factor model, which explained a significant 73.1% of the total explained variance. The model based on the 2010 data was simple, interpretable and parsimonious. In this model 100m hurdles (loading = .818) and 200m (loading=.793) loaded with factor 1, high jump (loading = .876) and long jump (loading = .711) with factor 2, shot put (loading = .750) and javelin (loading = .818) with factor 3, and 800m (loading = .940) with factor 4. No factor complexity was displayed as occurred with the 2006 data. **Discussion** The 2006 and 2010 data indicated different factor structure for each competitive season and therefore factor variance over time. This may reflect different training approaches or different ability athletes in terms of the seven event interrelationships between the 2006 and 2010 athletic seasons. However, the four factor model for the 2010 data to an extent simplifies approaches to heptathlon training. As the sprint, jump, throw and endurance events did load simply across the four factors, then training units can be based on these factors as they represent underpinning motor fitness factors, such as strength (throws), speed (100m hurdles, 200m), power (high jump, long jump) and endurance (800m). ## MOTOGP TREND ANALYSIS. A DECADE OF THE MOTORCYCLING WORLD CHAMPIONSHIP.

D'ARTIBALE, E.1,2, DI SPENSA, L.2, DI CAGNO, A.2, CALCAGNO, G.2

1 EDAPROJECT.NET ; 2 DEPARTMENT OF HEALTH SCIENCES, UNIVERSITY OF MOLISE, ITALY

**Introduction** Road racing motorcycling is competed in the oldest motorsports championship in the world, established by the FIM (Fédération Internationale de Motocyclisme) in 1949. Research and developments in engineering, mechanics, electronic systems and aerodynamics, make motorcycles faster and more competitive. The aim of this study was to examine race results of the top class of the FIM Road Racing World Championship Grand Prix from 2000 to 2009. **Methods** Data were obtained by official results of a total of 167 races held in the FIM Road Racing World Championship from 2000 to 2009. Official documents were posted from the race direction ([www.motogp.com](http://www.motogp.com)), and recorded in a purpose-built file on Epidata Software. Year, track, race duration, mean speed winner, gap, starting and finishing riders, race conditions, air and ground temperatures and crashes were the items selected for the analysis. Both descriptive and statistical analysis were applied. **Results** A total of 135 races satisfied the inclusion criteria and were analyzed. The average value of the mean speeds of the winners was 156.2±7 Km/h in 2000, 162.4±8 Km/h in 2005, and 160.7 ±7 Km/h in the 2009 season, determining a positive linear regression trend line (coefficient R<sup>2</sup>=0.65). The linear regression trend line of starting riders was negative (coefficient R<sup>2</sup>=0.44). No correlations between race temperatures (air and ground), mean speed winner and crashes were found. **Discussion** Race results from the top class of the FIM Road Racing World Championship Grand Prix from 2000 to 2009 showed that technology and developments made motorcycles faster and improved performance. Since road-race motorcycling imposes a high load on the riders, appropriate training programs for those athletes could be essential for road-race motorbike performances. Road racing motorcycling performance has a tendency to improve, although strict rules could limit the evolution of motorbikes, whereas, appropriate training for riders could represent a new frontier for performances evolution. ## A PILOT TEST ON THE PERCEPTION OF E-LEARNING IN THE UNIVERSITY OF SPORTS OF TIRANA

LILE, A., KAÇURRI, A.

UNIVERSITY OF SPORTS OF TIRANA

**Introduction** Teaching and learning methodologies in Higher Education Institutions of Albania are nowadays experiencing important changes. In this concern, University of Sports of Tirana (UST) has already realized the need for Learning Management System (LMS) implementation, based on students' and teachers' demands. E-Learning platforms enables educational institutions to improve the learning and teaching experience (Nichols 2003). **Methods** Participants in this study were 46 sports physical education students enrolled in 'Informatics and Statistics' course in Spring semester 2010 at UST. In this course Moodle (Moodle, 2010) Learning Management System (LMS) was used as a supportive tool. In order to evaluate the Moodle LMS, a pilot test was conducted using OLES (On-Line Learning Environment Survey), a web-based instrument that contains 54 items arranged in nine scales (Pearson & Trinidad 2004). **Results** Means of scores ranged from 1.60 to 3.41 for 'actual' and 3.21 to 4.72 for 'preferred'. Analyses of Variance (ANOVA) revealed significant differences for Computer Usage (CU), Personal Relevance (PR), Equity (EQ) and Asynchronicity (AS) scales in 95% confidence. The result revealed a large F

Ratio for CU, TS, SIC, PR, SA, EQ, EN, AS and a small one for AL. Discussion Results showed that students' actual e-learning environment was not satisfactory in Computer Usage, Personal Relevance, Equity and Asynchronicity scales. Measuring students' attitude towards e-learning was very valuable to get relevant findings since UST is planning to adopt an e-learning system (Bertea, 2009 ; Anarkia, 2004). The support on the items of these scales should be improved to increase the student perception. Findings of such a pilot study may still be useful to higher education institutions that are planning to implement e-learning platforms. References Anaraki, F., (2004). Developing an Effective and Efficient eLearning Platform, *International Journal of The Computer, the Internet and Management*, 12 (2), 57-63. Bertea P. (2009). ## **APPLYING DATA MINING TECHNIQUES IN E-LEARNING: CASE STUDY OF INFORMATICS AND STATISTICS COURSE AT THE UNIVERSITY OF SPORTS OF TIRANA**

LILE, A., KAÇURRI, A.

*UNIVERSITY OF SPORTS OF TIRANA*

**Introduction** The educational process in University of Sports of Tirana (UST) is currently facing several issues such as identifying students needs, predicting the quality of learning experiences etc. Educational Data Mining (EDM) has become an emerging research field used to extract knowledge and discover patterns from e-learning systems (Baker, 2010). The aim of this study is to describe a step by step process (Romero, & Garcia, 2007) of applying data mining techniques to e-Learning data, in order to discover interesting patterns. Methods Participants in this study were 29 sports physical education students enrolled in 'Informatics and Statistics' course in Spring semester 2010 at UST. In this course Moodle (Moodle, 2011) Learning Management System (LMS) was used as a supportive tool. In order to discover knowledge and discover interesting patterns from the Moodle LMS, several data mining techniques Attribute Weighting by Information Gain, Clustering ( K-Means) and Classification(Tree Induction) were applied (Romero, Ventura, & Garcia 2007). Rapid Miner (v5.0) data mining tool was used to extract knowledge from logs data, by mining summarized tables from moodle database. Results Weighting by Information Gain revealed Resource View as the most dominant activity. KMEANS (k=2) generated two groups of students based on their interactions in Moodle: Cluster 0 characterized by active students in moodle, with high assignment score number, which participated to the online quiz etc; and Cluster 1 characterized by inactive and moderately active students with a low number of actions in the logs. A set of IF-THEN-ELSE rules was generated from the decision tree operator classifying three main categories of students: 1) students with a low assignments score classified as FAIL; students with medium assignments score classified as FAIL or PASS depending on their quiz score, and students with a high assignments score classified as FAIL, PASS or EXCELLENT depending on number of hints in the system. Discussion The experimental results have shown that the data mining model presented in this study was able to obtain comprehensible and actionable feedback from the LMS data describing students' learning behavior patterns. This educational data mining work allowed identifying and locating information about e-Learning processes that need improvements. To further extend this research, more extensive experiments should be conducted by using larger data sets. References Baker , M.,(2010). Data Mining for Education. ## **ALTITUDE ADAPTATION AND TEAM SUCCESS DURING THE FIFA WORLD CUP 2010**

FAUDE, O., SCHMIDT, C., MEYER, T.

*SAARLAND UNIVERSITY*

**Introduction** During the FIFA World Cup 2010 matches were played from sea level up to an altitude of 1,700 m. Performance at altitude can be impaired without appropriate acclimatisation (Levine et al., 2008). Thus, the present descriptive analysis aimed at comparing the success of teams living at different altitudes during the World Cup. Methods Altitude of team hotels and stadiums was obtained from Google Earth. Team accommodation as well as match locations were assigned to 3 different categories: sea level (SL, <500 m, N=7), low altitude (LA, 500-1,500 m, N=16), and medium altitude (MA, >1,500 m, N=9). Match results and FIFA world ranking positions were obtained from [www.fifa.com](http://www.fifa.com). Information regarding the preparation period and arrival of the teams at their base camps were collected from mass media. Results Median world ranking position was similar in all altitude categories (19-22, p=0.78). All but one SL team were eliminated after the preliminary round. In addition, all quarterfinalists lived at an altitude above 1,100 m. Teams arrived at their base camps on average 7 days prior to the first match with no difference between categories (p=0.54). When playing against teams of lower altitude category winning and losing percentage was 44% [95%CI: 26-62%] and 22% [8-36%], respectively. Winning percentage of LA (40% [24-56%]) and MA teams (39% [28-50%]) was more than twice that of SL teams (18% [2-34%]). LA and MA had a better ratio of scored vs. received goals compared to SL (MA: 1.2 vs. 1.0 goals/match, LA: 1.3 vs. 1.1, SL: 0.7 vs. 1.3). MA teams showed the best relationship of scored vs. received goals (1.7 vs. 1.2 goals/match) when matches were played in Johannesburg (1,700 m) and scored most goals during the second half of the match. Discussion It is well established that teams living at altitude have an advantage compared to SL teams when competing at altitude. These effects might be caused by physiological and/or physical mechanisms (Levine et al., 2008). Impairments in maximal aerobic capacity and match play performance might be already present at altitudes above 500 m. Timely acclimatisation can counteract these altitude-associated physiological deteriorations. In addition, the considerably lower air density at altitude (17% lower in Johannesburg compared to SL) may have an impact on ball flight and sprint performance. In conclusion, the choice of accommodation during the World Cup might have influenced team success. When competitions take place at altitudes relevantly above sea level, it should be taken into account that altitude adaptation may have an advantage compared to living at sea level. Reference Levine BD, Stray-Gundersen J, Mehta RD. (2008) *Scand J Med Sci Sports*, 18 (Suppl 1), 76-84.

### PILOT STUDY TO DETERMINATE THERMAL ASYMMETRIES IN JUDOKAS

ARNAIZ LASTRAS, J., FERNÁNDEZ CUEVAS, I., GÓMEZ CARMONA, P.M., SILLERO QUINTANA, M., GARCÍA DE LA CONCEPCIÓN, M., PIÑONOSA CANO, S.

UNIVERSIDAD POLITÉCNICA DE MADRID

**Introduction** As a part of a new researching line about establishing a specific thermal profile for high performance athletes of each specialty, we have analyzed the irradiated heat variation in judokas. Infrared thermography is a fast and non-invasive technique to control muscular thermal balance. The aim of creating a thermal profile for each sport is based on controlling the thermal singularities, which could influence the thermographic interpretation (Ring et al., 2002). **Methods** We have developed a pilot study with 2 right-handed high performance judokas from the Spanish National League, with an average age of  $21,75 \pm 0,65$  years, weight of  $78,5 \pm 10,5$  kg, and height of  $187,5 \pm 4,5$  cm, and a minimal training frequency of 4 times per week. Our aim was to start with a small sample to set the main points for further researches about thermal profile for Judo athletes. Athletes were monitored for 5 months, since October until February, with a number of 10 thermographic assessments along this period. Images were taken following the patterns set by Gómez Carmona et al. (2010) patented protocol. All images were taken in the same isolated room and conditions: 10 minutes of acclimation; a temperature average of  $18,04^\circ\text{C}$  and a humidity of 43,75%. The assessments took place before the training session and the frequency was at least once per month. A T335 FLIR Thermographic camera was used to take the images, which were analyzed through TernoTracker 1.0.0.4 software. We used the average temperatures of each body areas in order to obtain thermal differences between bilateral body areas. **Results** After analyzing all thermal images through the software, bilateral significant differences ( $p < 0,05$ ) were only found on dorsal exterior forearm, with an upper 0.4-degree difference in favor of the dominant hand. **Discussion** The thermal results obtained are into the normal distribution established by Nomura Cabrera et al. (2008). In terms of the significant differences founded, they could be due to the asymmetry in the dominant forearm diameter in judokas -7% bigger- (Krawczyk, 1998), or the influence of the repetitive rotational movements characteristic from judo practice (Zakynthinaki, 2010). Furthermore, the 0.4-degree difference would not be considered as injury risk (Gómez Carmona et al., 2010) but a thermal singularity in judokas because of their practice. **References** Gómez Carmona, P. M. (2010). Spain Patent No. P201031080. Oficina Española de Patentes y Marcas: UPM. Krawczyk, B. (1998). ### VARIABILITY AND PREDICTABILITY OF FINALS TIMES OF ELITE ROWERS

SMITH, T.B., HOPKINS, W.G.

UNIVERSITY OF WAIKATO (HAMILTON, NEW ZEALAND), AUT (AUCKLAND, NEW ZEALAND)

**Introduction** Little is known about the competitive performance characteristics of elite rowers. We report here analyses of performance times for finalists at world cups, world championships and Olympics from 1999 to 2009. **Methods** A linear mixed model of finals times for single and crewed boats provided estimates of within-boat variability and between-boat differences as coefficients of variation. The model included terms to account for differences or changes in performance between calendar years, venues and the various levels of finals (A, B, C...). **Results** Differences in the effects of environmental conditions, estimated as variability in mean race time between finals, were very large to extremely large (2.3-4.0%), with possibly greater variability for singles compared with quads and eights. Within-boat race-to-race variability was 0.6-1.5% (90% confidence limits  $\times/\div 1.09-1.21$ ); singles were almost certainly more variable ( $>1.10\times$ ) than quads and eights, males were likely more variable than females, and variability in A finals of singles was very likely less than that in other finals. Smallest worthwhile enhancements in performance, given by  $0.3\times$  within-boat variability, ranged from  $\sim 0.3-0.4\%$  for the singles down to  $\sim 0.2\%$  for the eights. Between-boat differences in a given final ranged from small to large (0.5-2.0%), with differences for females likely more than those for males. Predictability of performance, expressed as within-year intraclass correlation coefficients, was moderate to very high (0.33-0.83), with females very likely to be more predictable than males. **Discussion** The environmental variability is of such a magnitude that B, C or even D finals could end up faster than A finals at a given venue, which is not uncommon. Overall, the variability of performance is similar to that in comparable endurance sports performed against water or air resistance but higher than that for elite middle distance track runners. We believe the additional variability for rowers compared with runners arises predominantly from environmental conditions; for example, a tailwind could benefit some rowers more than others, and a side wind could benefit rowers in lanes in which there is a wind shadow. The lesser variability for females is probably a consequence of more consistent motivation. Bigger differences in performance time between females, due presumably to less competitive depth, contributes to the higher predictability of competitive performance in females. The crewed boats show less variability than singles, probably because of less effect of the environment and some averaging of the variability of the individual crewmembers. The findings of this study will help inform investigations of factors affecting elite competitive rowing performance.

#### EFFECTS OF SHORT-TERM BETA-HYDROXY-BETA-METHYLBUTYRATE SUPPLEMENTATION ON MARKERS OF MUSCLE DAMAGE, SORENESS AND MUSCLE FUNCTION AFTER PROLONGED INTERMITTENT HIGH-INTENSITY SHUTTLE RUNNING

ALBERT GARCIA, F.J., ORTEGA PORCEL, F.B., RUIZ RUIZ, J., GONZALEZ GROSS, M.M., GUTIERREZ SAINZ, A., CASTILLO GARCION, M.J.

UNIVERSIDAD DE GRANADA

**Introduction** Most sports at the highest levels and annual training patterns demand high physiological, psychological, technical and tactical qualities from athletes. There is a need for an optimal turnover of those substances with high catabolic rate. Several nutritional ergogenic aids can contribute to optimize these processes. In this sense, HMB has been proposed to have an ergogenic effect on athletic

performance without having practically any adverse effect on the athlete's health. **Methods** Ten football players (18-25 yr) were supplemented along two supplementation periods. In the first period, 5 of the 10 subjects were supplemented with 3 grams of HMB per day for 8 days; the other 5 received a placebo (maltodextrin) followed by two weeks wash-out period and then a second supplementation period in a randomized double-blind crossover placebo design. Testing involved the Loughborough Intermittent Shuttle Test (LIST). Blood samples were collected before, after and the day after the LIST to determine muscle damage. Prior to and following supplementation, dietary records and fasting blood samples were also obtained. Lactate and muscle function (handgrip, CMJ and sprinting) was measured between sets and the day after the LIST. Rating of Perceived Exertion and Recovery was taken all along testing sessions. **Results** CK Levels tended to be lower when subjects were supplemented with HMB (916.1 vs 784.9 U/l, placebo vs HMB;  $p < 0.9$ ). On the other hand, we can appreciate that HMB supplementation improved jump capacity (Abalakov test) 24 hours after the LIST when compared to placebo (40.57 vs 42.84 cm + SD, placebo vs HMB;  $p < 0.01$ ). Similarly, HMB supplementation improved the average sprint time compared to placebo (3.3 vs 3.2 s + SD, placebo vs HMB;  $p < 0.02$ ). **Discussion** Trained football players receiving HMB supplementation (3 g/day, 8 days) improved their athletic performance 24 h after a high intensity intermittent exercise and show a tendency to limit their muscle catabolism after an exhaustive exercise test. This effect can contribute to decrease the accumulative effect on muscle damage caused by daily training sessions. These results are in agreement with those studies that support the efficacy of HMB as an effective ergogenic aid for athletes that decreases DOMS, markers of muscle damage, and body fat, while improving various markers of performance (Van Someren et al., 2005). In contrast, there are other studies that did not support the efficacy of HMB supplementation (Kreider et al., 2000). These authors suggest that these conflicting results may in part be attributed to the variability in humans, inadequate sample sizes, and methodological issues (Wilson et al., 2008). **References** • Kreider RB et al. ### THE EFFECT OF ACUTE BOVINE COLOSTRUM SUPPLEMENTATION ON NEUTROPHIL RESPONSES TO PROLONGED CYCLING

JONES, A., THATCHER, R., DAVISON, G.

ABERYSTWYTH UNIVERSITY

It has been suggested that in the hours or days following prolonged exercise an individual has increased susceptibility to upper respiratory tract infections (URTI) due to alterations in many immunological components (Nieman, 2001). Bovine colostrum (BC), consumed daily for 4-8 weeks, has been shown to be of benefit to the immune system and URTI risk (Brinkworth & Buckley, 2003; Davison & Diment, 2010). The purpose of this study was to identify whether acute BC supplementation (i.e. hours) prior to a bout of prolonged exercise has any effect on neutrophil function. Five healthy males (age: 21.6 [3.2] years, body mass: 74.0 [5.6] kg,  $\text{VO}_2$  max: 4.3 [0.7] L/min; values are mean [SD]) participated in 2 main trials in a randomised order. Subjects consumed either BC or placebo (PLA) 1 hour prior to 2.5 hours of cycling at approximately 55%  $\text{VO}_2$  max (30g), immediately prior (5g) and midway through the exercise (5g). Venous blood samples were obtained on the morning prior to consumption of the supplement, 1 hour post-drink (immediately pre-exercise), immediately post-exercise and 1 hour post-exercise. Total and differential leukocyte counts were measured using an automated haematology analyser. In-vitro stimulated neutrophil oxidative burst responses (OBA) to PMA and fMLP were measured by chemiluminescence (CL) assay and expressed per neutrophil. To maintain blinding procedures, the effect of trial on cell counts was not investigated so only overall time effects are reported. Repeated measures 1 way ANOVA and post hoc paired t-tests (Bonferroni corrected) revealed significant increases at both post-exercise timepoints for blood neutrophil count ( $P = 0.001$ ) and neutrophil:lymphocyte ratio ( $P \leq 0.001$ ). For fMLP-stimulated OBA 2-way repeated measures ANOVA showed a main effect of time ( $P < 0.001$ ) but no main effect of trial or time  $\times$  trial interaction ( $P > 0.05$ ). For PMA-stimulated OBA there was a main effect of time ( $P = 0.032$ ) and trial ( $P = 0.043$ ) but no time  $\times$  trial interaction ( $P > 0.05$ ). Post hoc comparisons demonstrated significant post-exercise decreases. These results suggest that OBA is generally higher with acute BC supplementation but the overall temporal pattern (a post-exercise decrease) is similar between trials. These preliminary results provide support for the idea that BC may enhance neutrophil functions by a direct and immediate mechanism, in agreement with the in-vitro findings of Sugisawa et al. (2001). At present statistical power is low and the intention is to increase the sample size to 12. Brinkworth & Buckley. (2003). *Eur J Nutr*, 42, 228-332. Davison & Diment. ### THE EFFECT OF SHORT TERM DIETARY MANIPULATION ON GROSS EFFICIENCY DURING CYCLING.

COLE, M., COLEMAN, D.A., WILES, J.D.

CANTERBURY CHRIST CHURCH UNIVERSITY

To assess the effect of short term dietary manipulation on gross efficiency, 14 trained male cyclists ( $\text{VO}_2\text{max}$   $56.6 \pm 7.2 \text{ ml} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ , mean  $\pm$  SD) completed three 2-hour tests at a steady-state submaximal exercise intensity (60% of Power at  $\text{VO}_2\text{max}$ ). In the 3-days preceding each test, participants consumed a diet (~4000kcal.day<sup>-1</sup>) that was either high in carbohydrate (High CHO, [70% carbohydrate, 20% fat, 10% protein]), low in carbohydrate (Low CHO, [70% fat, 20% carbohydrate, 10% protein]) or contained a moderate amount of carbohydrate (Mod CHO, [45% carbohydrate, 45% fat, 10% protein]) in a randomised, crossover designed study. Gross efficiency (GE) along with blood lactate and glucose were assessed at regular intervals (~30mins) and heart rate was measured continuously at 5 second intervals throughout the test. Mean GE was significantly greater following the High CHO diet than the Mod CHO diet. (High CHO =  $20.1\% \pm 0.5\%$ , Mod CHO =  $19.3 \pm 0.6\%$ , mean  $\pm$  SD;  $P < 0.05$ ). More specifically, GE was significantly greater after 25mins, 85mins and 115mins of the test ( $P < 0.05$ ). Dietary manipulation had no effect on blood glucose, blood lactate or heart rate responses during exercise ( $P > 0.05$ ). In conclusion, significant differences in gross efficiency were obtained following alteration of participants' diet in the 3-days preceding assessment. This suggests that before the measurement of gross efficiency takes place, participants' diet should be carefully controlled and monitored to ensure the validity of the results obtained.

### SIX DAYS OF BEETROOT JUICE INGESTION INCREASES MEAN POWER OUTPUT DURING A 10 KM TIME TRIAL IN TRAINED CYCLISTS

CERMAK, N.M.1,2, GIBALA, M.J.1, VAN LOON, L.J.C.2

1. MCMASTER UNIVERSITY 2. MAASTRICHT UNIVERSITY

**Introduction:** Recent work in humans suggests that the therapeutic potential of increased nitric oxide bioavailability may extend far beyond the well known hemodynamic effects. Six days of dietary nitrate supplementation using beetroot juice (0.5 L/d) reduces pulmo-

nary oxygen uptake (VO<sub>2</sub>) during submaximal exercise (1,2) and increases tolerance to higher-intensity workloads (1). These findings suggest that inorganic nitrate ingestion has the potential as a potent ergogenic aid. To date, no study has investigated this issue using a practical, performance-based study that simulates normal athletic competition. The primary purpose of this study was to determine whether 6 d of beetroot juice ingestion improves performance during a 10 km cycling time trial in trained athletes. Methods: Using a double-blind, repeated-measures crossover design, 13 trained cyclists or triathletes ( $31 \pm 3$  y; VO<sub>2</sub> peak =  $58 \pm 2$  mL/kg/min; W<sub>max</sub> =  $342 \pm 10$  W) ingested 140 mL/d of concentrated beetroot juice (Beet It, James White Drinks, Suffolk, UK) or a placebo (nitrate depleted beetroot juice, Beet It) for 6 d, separated by a washout period of  $\geq 14$  d. On the last day of supplementation in each trial, subjects performed a 1 h bout of submaximal cycling (30 min at each of 45 and 65% W<sub>max</sub>), followed immediately by a 10 km time trial using a CompuTrainer (RacerMate) and their own bicycle. Results: From 9 subjects that have completed all testing, mean power output during the time trial was higher after beetroot ingestion (BEET) compared with placebo (PLAC) ( $304 \pm 12$  vs  $296 \pm 12$  W, mean  $\pm$  SEM;  $P=0.04$ , 2-tailed t-test) and there was a trend towards an increase in time trial performance ( $950 \pm 21$  vs  $958 \pm 21$  s;  $P=0.09$ ). VO<sub>2</sub> at 65% W<sub>max</sub> was lower after BEET compared with PLAC ( $2.95 \pm 0.13$  vs  $3.16 \pm 0.12$  L/min;  $P=0.03$ ), with no differences observed between treatments at 45% W<sub>max</sub> ( $1.96 \pm 0.05$  vs  $2.05 \pm 0.09$  L/min, respectively;  $P=0.2$ ). Resting systolic and diastolic blood pressures, heart rate, respiratory exchange ratio and perceived exertion during exercise did not differ between treatments. Conclusion: Six days of nitrate-rich beetroot juice ingestion improves mean power output during a 10 km time trial in trained athletes. The mechanism for improved performance remains to be determined, but may be related to improved metabolic efficiency. References: 1. Bailey, SJ et al. (2009). J Appl Physiol 107: 1144-55. 2. ## PROLONGED RESISTANCE TYPE EXERCISE TRAINING AND PROTEIN SUPPLEMENTATION IN THE ELDERLY

LEENDERS, M., VERDIJK, L.B., VAN DER HOEVEN, L., VAN LOON, L.J.C.

MAASTRICHT UNIVERSITY MEDICAL CENTRE+

Resistance type exercise training has been well established as an effective treatment strategy to counteract sarcopenia in the elderly (1). Though the relevance of sufficient dietary protein intake has been recognized, it remains to be established whether protein supplementation can further augment the skeletal muscle adaptive response to prolonged resistance type exercise training in the elderly (2,3). In the present study, we aimed to determine the additional effect of protein supplementation with breakfast on muscle mass and strength during prolonged resistance type exercise training (RT) in healthy elderly men and women. A total of 30 men ( $70 \pm 1$ y) and 30 women ( $70 \pm 1$ y) were included in a supervised and progressive whole body RT program, with 3 training sessions per week for 24 weeks. On a daily basis, subjects consumed a drink after breakfast, containing either 15g of protein or a placebo. Muscle strength was determined with 1 repetition maximum (1RM). Body composition was assessed by DEXA scan, cross sectional area of the quadriceps muscle was assessed by CT scan, and muscle biopsies were collected to assess muscle fiber type composition and muscle fiber size. All measurements were performed before, and after 12 and 24 weeks of intervention. So far, 22 subjects completed the intervention program. 1RM strength increased by  $29 \pm 2\%$  for the leg press, and  $45 \pm 4\%$  for the leg extension ( $P < 0.05$ ). In accordance, leg lean mass increased from  $18.1 \pm 0.6$  to  $18.7 \pm 0.7$  kg, and quadriceps muscle cross-sectional area increased from  $63.5 \pm 2.4$  to  $67.9 \pm 2.6$  cm<sup>2</sup> following the intervention. Whole body fat mass decreased from  $21.8 \pm 1.0$  to  $20.2 \pm 0.9$  kg. More results from the entire group of participants, including the impact of additional protein supplementation with breakfast, will be finalized within 3 months and will be presented at the conference. So far, the present study clearly shows that prolonged resistance type exercise training in elderly males and females increases muscle mass, augments muscle strength, and stimulates fat mass loss. ## TWELVE WEEKS OF A WESTERN DIET ENHANCES THE RESPIRATORY CAPACITY OF OXIDATIVE SKELETAL MUSCLE

STEPHENSON, E.1, STEPTO, N.2, KARAGOUNIS, L.1, KOSARI, S.1, JENKINS, T.1, HAWLEY, J.1

1: RMIT UNIVERSITY 2: VICTORIA UNIVERSITY

Introduction Mitochondrial respiratory capacity is enhanced following both a bout of endurance exercise and a period of high-fat feeding. Both endurance exercise and high-fat diets (HFD's) increase circulating free fatty acids (FFA's), and it is thought that chronic FFA-induced activation of peroxisome proliferator-activated receptor (PPAR) delta and subsequent increases in PPAR gamma coactivator-1 alpha (PGC-1a) are responsible for promoting mitochondrial biogenesis. Combined with endurance training, HFD's have been shown to amplify training adaptation by increasing key enzymes of the beta-oxidation pathway and the overall rate of fat oxidation, however HFD's are also associated with weight gain and disturbances in glucose homeostasis. Similar to a HFD, FFA's also increase following a "Western-style" diet (WD; typically containing ~20% protein, 20% fat and 60% carbohydrate). We hypothesize that skeletal muscle respiratory capacity may therefore be enhanced following a WD. Methods Nine wk old male Long-Evans rats (weight  $273.82 \pm 2.6$  g, values are mean  $\pm$  SEM) consumed a control diet (CON, N=12; 73% carbohydrate, 7% fat, 20% protein; 16.1 kJ/g) or WD (N=12; 60% carbohydrate, 21% fat, 19% protein; 19.4 kJ/g) for 12 wk. Glucose tolerance, body mass and fat pad mass were measured. Mitochondrial respiration was assessed ex vivo in permeabilized fibres from the soleus using high-resolution respirometry. Results From 6 wk, WD rats were heavier than CON ( $379.10 \pm 7.14$  and  $356.66 \pm 3.97$ , respectively;  $P=0.012$ ) and remained heavier throughout the intervention. After 12 wk, epididymal fat pads were heavier in WD compared to CON ( $8.06 \pm 0.35$  and  $6.90 \pm 0.32$ , respectively;  $P=0.028$ ). Fasting serum glucose concentrations were elevated in WD compared to CON (12.5%,  $P=0.013$ ), although glucose tolerance was similar. In the soleus muscle (~87% slow oxidative fibres), respiratory capacity of complex I, complexes I & II together, & maximal uncoupled respiration was greater in WD compared to CON (all  $P < 0.05$ ). Respiratory capacity of complex II did not differ between groups. Conclusion Surplus energy intake through a WD increases the respiratory capacity of oxidative muscle from rodents. It is unknown whether this occurs via the same mechanisms thought to be induced by a bout of endurance exercise or a HFD. Further investigations are necessary to address this question.

## EFFECTS OF ALKALOSIS ON PERFORMANCE AND MUSCULAR OXYGENATION DURING ALL-OUT CYCLING EXERCISES

DELFOUR-PEYRETHON, R.

INSTITUT NATIONAL DU SPORT, DE L'EXPERTISE ET DE LA PERFORMANCE

Effects of alkalosis on performance and muscular oxygenation during all-out cycling exercises Delfour R 1,2, Hanon C1, Dorel S 1,2, Perrey S 4, Bishop D 5, Leprêtre P-M 3 and Thomas C 1,6 1 French National Institute of Sports (INSEP), Laboratory of biomechanics and physiology - 11 Tremblay Avenue, 75012 PARIS, France 2 University of Nantes, Laboratory « Motricité, Interactions, Performance » (EA 4334), F-44000, Nantes, France 3 University of Picardie Jules Verne, 80025 Amiens cedex, France 4 Laboratoire de Recherche Efficience et Déficience

Motrices, EA-2991, UFR-STAPS, Université de Montpellier 1, Montpellier, France 5 Institute of Sport, Exercise and Active Living (ISEAL), Victoria University, Melbourne, Australia 6 University of Evry Val d'Essonne, STAPS department, UFR SFA, François Mitterrand Boulevard 91025 Evry, France Key words: alkalosis, track-cycling, muscular oxygenation. The aim of this study was to evaluate the performance during all-out exercise tests with or without induced metabolic alkalosis, and to determine the oxygenation pattern of two specific cycling muscles: Biceps Femoris (BF) and Vastus Lateralis (VL). This parameter was measured by Near Infrared Spectroscopy (NIRS), a noninvasive and validated method using the absorption differences of light emitted in the infra-red close relation by the molecules of oxyhaemoglobin (HbO<sub>2</sub>) and deoxyhaemoglobin (HHb) (1). Twelve males, well-trained in cycling, successively performed two 70s identical all-out exercises (delta 30% between P-VO<sub>2</sub>max and Pmax) individually pre-established by a VO<sub>2</sub>max test (P-VO<sub>2</sub>max) and a strength-speed test (Pmax) on cycle ergometer. This study was conducted in a double-blind fashion, either after ingestion of a placebo (PLA) or after 0.3g.kg<sup>-1</sup> of sodium bicarbonate (BIC). Levels of HbO<sub>2</sub> and HHb were recorded on the surface of the BF and VL. Blood samples were taken before exercise and during recovery. The mean power (W) was significantly improved in BIC condition (P<0.01). After a steady state at rest, HHb increased and HbO<sub>2</sub> decreased, both significantly (P<0.001) from the onset of exercise. Although these patterns are previously observed in the literature (2), no significant difference of muscular oxygenation was observed according to experimental conditions. However, we noted a significant increase in HHb between the twentieth second and the end of exercise for the VL in both conditions whereas HHb remained stable for the BF. In conclusion our results suggest that muscular oxygenation of two specific muscles of cycling is not altered with induced alkalosis for this type of exercise, whereas the performance is improved. 1- Grassi B, Pogliaghi S, Rampichini S, Quaresima V, Ferrari M. ### EFFECTS OF PRE-EXERCISE INGESTION OF SODIUM AND GLUCOSE ON PHYSIOLOGICAL RESPONSES AND PERFORMANCE DURING EXERCISE IN THE HEAT

SUGIHARA, A.1, FUJII, N.2, TSUJI, B.1, WATANABE, K.1, NIWA, T.1, NISHIYASU, T.3

1: UNIVERSITY OF TSUKUBA, 2: JSPS FELLOW, 3: UNIVERSITY OF TSUKUBA

**Introduction** It has been suggested that pre-exercise hyperhydration using sodium-containing drinks reduces cardiovascular and heat strain during exercise, thereby improving exercise performance (Sims et al., 2007). Moreover, the effect of pre-exercise hyperhydration might be enhanced by adding glucose to the sodium drink, as the combination could stimulate sodium-glucose co-transporter activity in the intestinal membrane. We therefore examined the effects of pre-exercise ingestion of sodium-only and sodium-glucose drinks on physiological responses and performance during exercise in the heat. **Methods** Nine healthy men ingested a given amount (16-17 ml/kg body weight) of water (W) or a drink containing 0.7% NaCl (Na: 120 mEq/l Na+) or 0.7% NaCl + 6% Dextrin (Na+Dex: 120 mEq/l Na+, 58.34g/l dextrin) before conducting 90-min cycling at 50%VO<sub>2</sub>peak (SubEx), followed by cycling at 100%VO<sub>2</sub>peak until exhaustion (MaxEx) in the heat (35°C, 50%RH). **Results** Plasma volume (PV) was higher in Na and Na+Dex than in W before and during SubEx (P<0.05), and tended to be higher in Na+Dex than in Na before SubEx. Heart rate (HR), esophageal temperature (Tes) and mean arterial pressure (MAP) during SubEx were lower in Na and Na+Dex than in W (P<0.05), and did not differ between Na and Na+Dex during SubEx. MaxEx duration tended to be longer in Na than W, and was significantly longer in Na+Dex than W (P<0.05). MaxEx duration also tended to be longer in Na+Dex than Na. **Discussion** Previous study suggested that restoration of PV during exercise enhances skin vasodilation (a thermoregulatory response) and reduces Tes. Similarly, the higher PV in Na and Na+Dex may have induced greater skin vasodilation, contributing to a lower Tes in Na and Na+Dex. Moreover, if skin vasodilation was greater in Na and Na+Dex, total peripheral resistance may have been lower, leading to the lower MAP in those groups. On the other hand, Anderson et al. (2001) suggested that glycerol-induced hyperhydration improved 15-min maximal cycling performance following 90-min moderate-intensity cycling due to reductions in thermal and cardiovascular strain. The same mechanism could account for MaxEx duration being longer in Na and Na+Dex than W, since HR and Tes during SubEx were lower in Na and Na+Dex than W. In addition, greater glucose availability in Na+Dex might have increased MaxEx duration in Na+Dex over Na. **References** Anderson MJ, Cotter JD, Garnham AP, Casley DJ, Febbraio MA (2001). *Int J Sport Nutr*, 11, 315-333. ### CAN PROTEINS INFLUENCE BRAIN-DERIVED NEUROTROPHIC FACTOR TYPE 2 DIABETIC PATIENTS?

TONOLI, C., HANSEN, D., HEYMAN, E., VAN LOON, L.J.C., MEEUSEN, R.

VRIJE UNIVERSITEIT BRUSSEL

**CAN PROTEINS INFLUENCE BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) TYPE 2 DIABETIC PATIENTS?** Tonoli, C.1, Hansen, D.2, Heyman, E.3, van Loon, L.J.C.2, Meeusen, R.1 1: VUB (Brussels, Belgium), 2: UM (Maastricht, The Netherlands), 3: UL (Lille, France) **Introduction** Longstanding Type 2 Diabetes Mellitus (T2DM) is associated with impaired cognitive function (Awad et al., 2004). Brain-derived neurotrophic factor (BDNF) is known to regulate synaptic plasticity, neurogenesis and neuronal survival. BDNF has also been suggested to play a major role in glucose metabolism due to its hypoglycaemic effects ascribed to a better insulin sensitivity (Krabbe et al., 2007). Since it is known that the oral ingestion of proteins also lowers blood glucose levels (Manders et al., 2006, 2009), it might be interesting to find out whether the ingestion of proteins also influences BDNF levels. We hypothesized that there is a better absorption of hydrolysed proteins and thus might influence blood glucose and BDNF levels even more. Therefore, we explored whether BDNF levels are influenced by an orally administered protein (hydrolysed) mixture. **Material & Methods** Forty-five T2DM patients (aged 60 ± 7.6y, BMI 29.93 ± 3.49 kg/m<sup>2</sup>) underwent 3 experimental trials in which either 0.7 g.kg<sup>-1</sup>.h carbohydrates (CHO), CHO + protein (PRO) (0.35 g.kg<sup>-1</sup>.h) or CHO + hydrolysed (H) protein (0.35 g.kg<sup>-1</sup>.h) were administered. During 4 hours, glucose levels, insulin levels and BDNF levels were measured. Statistical analysis of the data were performed using a two factor repeated measures analysis of variance (ANOVA). Correlations were calculated using Pearson's analysis. **Results** BDNF levels were not significantly increased in the CHO trial compared with the CHO + H PRO trial. In accordance with previous research, a significant decrease of all blood glucose values in the CHO + PRO trial and CHO + H PRO trial comparing the CHO trial (p<0.01), suggesting proteins stimulate a higher sensitivity for insulin. The hydrolyzed protein trial did not produce significant lower blood glucose levels compared to the not hydrolyzed protein trial. Further, an inverse relationship between BDNF levels and glucose concentrations was found in all trials after ingestion of the carbohydrate fluid, although they were not significant. **Discussion** Because of the significant decrease of blood glucose values in the protein trials, we demonstrated that proteins stimulate a higher sensitivity for insulin and play, like BDNF, also a role in glucose metabolism. Although, BDNF levels were not significantly increased in the CHO trial compared with the CHO + H PRO trial, this can suggest that proteins do not play a role in increasing BDNF levels and therefore we have to reject our hypothesis. **References** Awad N, et al. UNIVERSITY KULEUVEN

**Purpose:** Recent studies have shown that dietary nitrate supplementation reduces the oxygen cost of muscle contractions and enhances endurance exercise performance (1; 2). We hypothesized that these effects may be particularly relevant during exercise in hypoxia. Therefore, we investigated the effects of nitrate intake on muscle and brain oxygenation status and exercise performance at simulated altitude corresponding to Everest Base Camp (5,300m). **Methods:** In a randomized single-blind cross-over design ten male subjects (age  $25.6 \pm 1.4$  yr,  $\text{VO}_2\text{peak}$   $63 \pm 2.5$  mL.kg<sup>-1</sup>.min<sup>-1</sup>) received either beetroot juice containing 0.07mmol nitrate per kg b.w. per day (BR), or apple-black current juice serving as a placebo (PL), for 6 days preceding the experimental sessions. Subjects participated in two experimental sessions in a hypoxic facility @ 11% oxygen content, separated by a 2-weeks wash-out period. In each session and after a 2-hr rest period they performed a submaximal cycling test (EX30%, 20 min @ 30% sea level  $\text{W}_{\text{max}}$ ) as well as an incremental  $\text{VO}_2\text{max}$  test (EXmax, 50W + 20W.min<sup>-1</sup>). During exercise, oxygen uptake ( $\text{VO}_2$ ) (Cortex Metalyzer II) and blood lactate (Lactate Pro) were measured. Furthermore, tissue oxygenation status (TOI) in m. vastus lateralis and frontal cerebral cortex were assessed using near-infrared spectroscopy (Niro-200, Hamamatsu). **Results:** Compared with PL, during EX30% BR slightly reduced  $\text{VO}_2$  during the initial stage of exercise (-5%,  $P < 0.05$ ) but not during final stage. BR increased muscle TOI by 6% ( $P < 0.05$ ), while cerebral TOI was not significantly changed. BR reduced blood lactate during EX30% by ~10% ( $P < 0.05$ ). Compared with PL, during EXmax BR increased time-to-exhaustion by 4% ( $P < 0.05$ ) whilst  $\text{VO}_2\text{max}$  was 5% lower ( $P < 0.05$ ). Furthermore, BR also reduced systolic blood pressure (BR:  $123 \pm 2$  vs. PL:  $129 \pm 3$  mmHg,  $P < 0.01$ ). **Conclusion:** Six days of dietary nitrate supplementation improves oxygen efficiency during exercise at extreme altitude. **References:** 1. ## DOES COINCIDING EXERCISE ONSET WITH PEAK CAFFEINE LEVELS IMPROVE CYCLING PERFORMANCE?

SKINNER, T.L.1, TAAFFE, D.R.2, LEVERITT, M.D.3, COOMBES, J.S.1, JENKINS, D.G.1

1: THE UNIVERSITY OF QUEENSLAND (BRISBANE, AUSTRALIA), 2: THE UNIVERSITY OF NEWCASTLE (OURIMBAH, AUSTRALIA), 3: GRIFFITH UNIVERSITY (GOLD COAST, AUSTRALIA)

**Introduction** Although the use of caffeine to enhance endurance performance is well documented, the optimal dose and timing of supplementation remains unclear. The ergogenic effect of caffeine is often assumed to be related to the levels of circulating drug present within the blood. The aim of this study was therefore to determine whether coinciding peak serum caffeine concentration with the onset of exercise would result in further improvements in performance compared with beginning exercise a standard one hour post-supplementation. **Methods** In this randomised, placebo controlled, double-blind crossover study, 14 male trained cyclists and triathletes (age  $31 \pm 5$  yr, body mass  $75.4 \pm 5.7$  kg,  $\text{VO}_2\text{max}$   $69.5 \pm 6.1$  mL.kg<sup>-1</sup>.min<sup>-1</sup> and peak power output  $420 \pm 35$  W, mean  $\pm$  SD) consumed 6 mg.kg<sup>-1</sup> caffeine or a placebo either 1 hour (C1h) prior to completing a 40 km time trial (TT40) in the laboratory or when the start of exercise coincided with individual peak serum caffeine concentrations (Cpeak). Cpeak was determined from a separate 'caffeine profiling' session that involved monitoring caffeine concentrations in the blood every 30 min over a 4-hour period. The trials were preceded by a standardised pre-exercise meal (2 g.kg<sup>-1</sup> carbohydrates) and subjects were tested for hydration and caffeine abstinence. Venous blood was sampled at baseline, 65 and 20 min prior to exercise and 6 min post-exercise for the measurement of serum caffeine, plasma glucose, catecholamine and blood lactate concentrations. **Results** Following caffeine ingestion, peak serum caffeine occurred 120 min in 12 participants and 150 min in 2 participants. Time to complete TT40 was significantly faster (2%;  $p = 0.002$ ) in C1h compared to placebo. A 1% improvement in performance was noted in Cpeak versus placebo, although this was not statistically significant ( $p = 0.240$ ). Whilst no differences in metabolic markers were found between Cpeak and placebo conditions, significant increases in glucose ( $p = 0.005$ ), norepinephrine and epinephrine ( $p = 0.002$ ) were observed in the C1h trial 6 min post-exercise versus placebo. **Discussion** The present study suggests that endurance cycling performance is enhanced when caffeine is ingested one hour prior to exercise. However, no significant improvements in performance were observed when peak serum caffeine concentrations coincided with the onset of exercise. Consequently, it appears that it is the temporal proximity of caffeine supplementation to the commencement of endurance exercise, rather than the achievement of peak serum caffeine concentration, that influences the ergogenic potential of caffeine.

## THE EFFECT OF VITAMIN C SUPPLEMENTATION ON THE AEROBIC PERFORMANCE

GEESMANN, B.1, WONNEBEGER, M.1, WEBER, S.1, KOEHLER, K.

1: GERMAN SPORT UNIVERSITY

**Introduction** It is beyond controversy that physical activity leads to an endogenous production of free radicals, namely and most importantly reactive oxygen species (ROS). It is assumed that the formation of ROS occurs during cellular respiration when a small share of the metabolized oxygen is converted to free radicals (Clarkson, 1995). The production of free radicals has been shown to affect the mitochondrial adaptation. Vitamin C has antioxidative properties and can reduce oxidative stress (Clarkson & Thompson, 2000) by neutralizing ROS action, which may affect exercise-induced mitochondrial adaptation (Finaud et al., 2006; Gomez-Cabrera et al., 2008). Hence, the aim of the present study was to investigate whether vitamin C supplementation during endurance training has a negative effect on aerobic performance capacity. **Methods** Fifteen subjects (weight:  $73.5 \pm 11.1$  kg, age:  $22.7 \pm 3$  y) participated in a placebo-controlled training study. Subjects were randomly assigned to the vitamin C-group (dose: 1000mg/d) or placebo-group. The subjects were enrolled in an interval training regimen with three exercise units per week. Before and after the 9-week supplementation period, each participant performed a  $\text{VO}_2\text{max}$ -test on a treadmill, a  $\text{VO}_2\text{max}$ -test on a bicycle ergometer and a submaximal (incremental) running test for the assessment of the running velocity at capillary blood lactate concentration of 4 mmol/l (v4). **Results** In both groups endurance performance capacity was significantly improved following the training -regimen. There was a non-significant tendency in favor of larger increases in the placebo-group when compared with the vitamin C-group. Absolute  $\text{VO}_2\text{max}$  (running):  $9.4 \pm 3.1\%$  vs.  $8.7 \pm 7.6\%$ ; relative  $\text{VO}_2\text{max}$  (running):  $10.9 \pm 2.9\%$  vs.  $9.1 \pm 7.7\%$ ; v4:  $12.8 \pm 8.3\%$  vs.  $10.4 \pm 7.3\%$ .  $\text{VO}_2\text{max}$  (cycling) and heart rate curves in the sub maximal running test showed inconclusive results. **Discussion** We did not find any significant differences with respect to the adaptation of endurance performance following vitamin C-supplementation. However, the tendency towards better improvements following placebo application indicates, that vitamin C-supplementation may neutralize ROS and lead to suboptimal mitochondrial adaptation. Further studies are neces-

sary to identify these effects with sufficient statistical power. References Clarkson P.M. (1995). *Crit Rev Food Sci Nutr*, 35, 131-41. Clarkson P.M., Thompson H.S. ### ATTITUDES, KNOWLEDGE AND AWARENESS OF DIRECTORS OF PHYSICAL EDUCATION ON THE USE OF DIETARY SUPPLEMENTS AND ERGOGENIC AIDS BY ADOLESCENT ATHLETES – IS THERE A POLICY NEED?

DESBROW, B., STEPHENS, E., LEVERITT, M.D.

GRIFFITH UNIVERSITY

The efficacy and long-term safety of dietary supplement (DS) and ergogenic aid (EA) use by adolescent athletes are factors largely unknown due to the ethical complications of testing such products on this population. Despite this, the use of DS and EA, by adolescent athletes is common. How adolescents, within the Australian school environment, are guided with respect to DS and EA use remains unclear. This study aimed to reveal Heads/Directors of PE/Sports current attitudes, knowledge and awareness of DS and EA use by adolescent athletes. Additionally, the study aimed to investigate school policies and/or guidelines associated with DS and EA use by adolescent athletes. Initially 35 private secondary schools and public secondary schools with sporting excellence programs from south east Queensland were invited to participate. Representatives from 13 schools (37% response) agreed to an individual semi-structured interview which were subsequently thematically analysed. Results indicated an awareness of supplement use by students. Prevalence of supplement use was largely unknown. Sports drinks were the most commonly reported DS and/or EA provided to adolescent athletes within the school setting, while one school indicated the provision of protein powder. Awareness by Heads/Directors of PE/Sport of credible and reliable information on DS and EA is limited. The investigation did not identify a school policy of any kind regarding DS and EA use. The majority of Heads/Directors of PE/Sport were supportive of a school policy of some kind. The primary expected outcome of such a policy, as indicated by Heads/Directors of PE/Sport, would be the ability to provide more consistent advice and/or guidelines to adolescent athletes, across all school staff and in particular, school appointed coaches.

### DEVELOPMENT OF A SPORTS NUTRITION KNOWLEDGE QUESTIONNAIRE FOR SOCCER

MARIDAKI, M.1, CHRYSSANTHOPOULOS, C.1, PAFILI, Z.1, SOUGLIS, G.A.1, PETRIDOU, A.2, MOUGIOS, V.2

1. UNIVERSITY OF ATHENS, 2. ARISTOTLE UNIVERSITY OF THESSALONIKI

**Introduction** The purpose of the study was to design a specific sports nutrition knowledge questionnaire (Q) for soccer. **Methods** The Q was designed in Greek by five experts (2 sports dietitians, 2 exercise physiologists and 1 exercise biochemist) and consisted of two sections, that is, a section of 40 questions on general nutrition concepts (GS), and a specific section of 60 questions on sports nutrition (SS). To test the validity the Q was distributed to 4 groups of 50 persons each: 1) dietitians, 2) sports scientists specialized in exercise physiology or/and sports nutrition, 3) physical education and sports science students (PES) and 4) life insurance employees. Furthermore, a group of 23 PES completed the Q before and after a 10-week course on sports nutrition (SN). Groups 1 and 4 completed the Q twice in order to test its reliability. The Q was also translated in English, and the two versions were administered to 50 Greek native speakers with a British university degree or a university degree in English literature (group 5). **Results** The overall, GS and SS scores were higher ( $p < 0.01$ ) in groups 1 (Overall:  $84.7 \pm 1.2$ ; GS:  $37.1 \pm 0.3$ ; SS:  $47.6 \pm 1.2$ ) and 2 (Overall:  $83.5 \pm 1.0$ ; GS:  $35.6 \pm 0.3$ ; SS:  $47.9 \pm 0.8$ ) compared to groups 3 (Overall:  $54.3 \pm 1.2$ ; GS:  $24.3 \pm 0.7$ ; SS:  $30.0 \pm 0.7$ ) and 4 (Overall:  $44.5 \pm 1.6$ ; GS:  $22.4 \pm 0.8$ ; SS:  $22.1 \pm 1.2$ ) (mean  $\pm$  SE). The overall and SS scores in group 3 were higher ( $p < 0.01$ ) compared to group 4. Also, the SN group scored higher ( $p < 0.01$ ) after the 10-week sports nutrition course (Overall:  $73.6 \pm 2.0$ ; GS:  $32.3 \pm 1.0$ ; SS:  $41.3 \pm 1.3$ ) compared to before (Overall:  $64.3 \pm 1.7$ ; GS:  $29.7 \pm 0.9$ ; SS:  $34.6 \pm 1.5$ ). The correlation coefficients between the first and second time of completion of the Q in groups 1 and 4 for the overall, GS, and SS scores were 0.98, 0.96, and 0.98, respectively. The corresponding correlations between the Greek and English versions in group 5 were 0.94, 0.84, and 0.94 ( $p < 0.01$ ). **Discussion** These data suggest that the Q developed is valid and reliable; thus, it can be used to test the sports nutrition knowledge of soccer players and coaches.

#### AEROBIC EXERCISE TRAINING FOR PATIENTS WITH EARLY ABDOMINAL AORTIC ANEURYSM DISEASE: A FEASIBILITY STUDY

TEW, G.A., MOSS, J., MITCHELL, P., NAWAZ, S.

SHEFFIELD HALLAM UNIVERSITY

At present, no effective medical strategy exists for patients with early abdominal aortic aneurysm (AAA) disease (i.e., those with an AAA diameter 30-55 mm); most of these individuals enter a serial surveillance programme under the guise of 'watchful waiting'. Aerobic exercise training might be a useful therapeutic tool for these patients, because it has the potential to reduce aneurysm progression via improved aortic haemodynamics and reduced inflammation (Dalman et al., 2006: *Annals of the New York Academy of Sciences*, 1085, 92-109), reduce the risk of many chronic diseases (e.g. coronary artery disease), and increase cardiopulmonary fitness. However, the role of exercise training for patients with early AAA disease is currently unclear. The purpose of this preliminary study was to investigate the safety of aerobic exercise training and its effect on cardiopulmonary fitness in patients with early AAA disease. With Local Research Ethics Committee approval, 23 patients with early AAA disease (age  $71.5 \pm 6.8$  y, AAA diameter  $40 \pm 7$  mm) were randomly allocated either to a supervised exercise training group or a no-exercise control group. Patients in the exercise group completed three 35-45 minute sessions of aerobic exercise per week for 12 weeks. The exercise involved treadmill walking and stationary cycling at a light-to-moderate intensity (11-13 on Borg's 6-20 Rating of Perceived Exertion Scale; Borg, 1998: Borg's rating of perceived exertion and pain scales. Leeds: Human Kinetics). The safety of the exercise intervention was assessed by monitoring changes in aneurysm diameter (B-mode ultrasonography) between baseline and 12 weeks, as well as the frequency of exercise-related adverse events. The effectiveness of the exercise programme was primarily determined by assessing changes in ventilatory threshold (breath-by-breath gas analysis during an incremental cycling protocol) between baseline and 12 weeks. Effect sizes (Cohen's d) were calculated as the difference between the standardised

mean changes for the exercise and control groups (Morris, 2008: Organizational Research Methods, 11, 364–386), with 0.2, 0.5 and 0.8 considered small, moderate and large effects, respectively. Eighteen patients completed the study (exercise  $n = 7$ , control  $n = 11$ ). Mean compliance to the exercise programme was 98%. There was no evidence of exercise-related aneurysm enlargement (e.g., AAA diameter: exercise  $43 \pm 7$  to  $44 \pm 7$  mm, control  $38 \pm 6$  to  $39 \pm 6$  mm;  $d = 0$ ) and no exercise-related adverse events. There was a larger increase in ventilatory threshold in the exercise group than the control group (exercise  $14.2 \pm 3.0$  to  $16.5 \pm 3.9$  mL $\cdot$ kg $^{-1}$  $\cdot$ min $^{-1}$ , control  $12.9 \pm 3.7$  to  $13.2 \pm 3.8$  mL $\cdot$ kg $^{-1}$  $\cdot$ min $^{-1}$ ;  $d = 0.54$ ). Our preliminary findings suggest that light-to-moderate aerobic exercise training in the form of treadmill walking and stationary cycling is safe and can improve cardiopulmonary fitness in patients with early AAA disease. More patients will be recruited to test the consistency of this finding.

## CEREBROVASCULAR RESPONSES DURING HEAD-UP TILT ARE WELL-MAINTAINED FOLLOWING INTERMITTENT EXERCISE

LEWIS, N.C.S.1,2, JONES, H.1, AINSLIE, P.N.2, LUCAS, S.J.E.3, THOMPSON, A.1, MARRIN, K.1,4, ATKINSON, G.1

1.LIVERPOOL JOHN MOORES UNIVERSITY, UK; 2.UNIVERSITY OF BRITISH COLUMBIA OKANAGAN, CANADA; 3.UNIVERSITY OF OTAGO, NZ; 4.EDGE HILL UNIVERSITY, UK

**Introduction** Postural syncope is common following prolonged, continuous-exercise (CON). Postural-related reductions in middle cerebral artery velocity (MCAv), mean arterial blood pressure (MAP) and stroke volume (SV) are exaggerated after 30 min of CON, but orthostatic tolerance itself is not compromised (Murrell et al., 2010). Daily living and many team sports involve intermittent-exercise (INT) rather than CON. Although it is emerging that INT can elicit very different physiological responses than CON (Jones et al., 2009), the specific responses to a postural change following INT are unknown. Therefore, this study is the first to examine the cardiovascular and cerebrovascular responses to a head up-tilt following 30 min of INT. We hypothesised that the postural-related reductions in MCAv would be greater following INT. **Methods** Nine healthy participants aged  $27 \pm 3$  yrs, completed three 10-min bouts of cycling at 60% of max work rate (MWR), with each bout separated by 10 min of rest. Another sample of 12 healthy participants aged  $25 \pm 1$  yrs completed a single 10-min bout of cycling at 50% MWR. Continuous beat-to-beat recordings of MCAv, MAP, SV, cardiac output (CO), heart rate (HR), and end-tidal carbon dioxide (PETCO<sub>2</sub>) were obtained during supine rest and a 60° head up-tilt (15 min) prior to and following the exercise protocols. Pre-post-exercise differences were analysed using paired t-tests and reported as mean $\pm$ SE. **Results** Tolerance to the head up-tilt was unaffected by both INT and CON ( $P > 0.10$ ). Following INT, resting HR and CO were elevated by  $8 \pm 2$  beats $\cdot$ min $^{-1}$  and  $1.2 \pm 0.03$  L $\cdot$ min $^{-1}$  respectively ( $P \leq 0.02$ ). The postural reductions in mean MCAv, MAP, SV, CO, and PETCO<sub>2</sub> were unaffected by INT ( $P \geq 0.12$ ). Following CON, resting mean MCAv, and HR were elevated by  $8 \pm 0$  cm $\cdot$ s $^{-1}$  and  $7 \pm 0$  beats $\cdot$ min $^{-1}$  respectively, whereas MAP was reduced by  $6 \pm 0$  mm Hg ( $P \leq 0.04$ ). Postural reductions in mean MCAv and CO were  $8 \pm 3$  cm $\cdot$ s $^{-1}$  and  $0.6 \pm 0.1$  L $\cdot$ min $^{-1}$  greater respectively following CON ( $P \leq 0.03$ ). **Discussion** Unlike after CON, our data indicate that the cerebrovascular and cardiovascular responses to head-up tilt are well-maintained following INT, even if the total exercise duration is longer. This differential influence of exercise type on cardiovascular and cerebrovascular control during orthostatic stress has implications for exercise prescription to individuals with an underlying medical condition (e.g. autonomic failure) which may increase the risk of cerebral hypoperfusion and the onset of postural syncope following exercise. **References** Jones H et al. (2009). Chronobiol Int, 26, 293-306. Murrell CJ et al. (2010). Exp Gerontol, 46, 1-8.

## SEDENTARY BEHAVIOUR OR PHYSICAL ACTIVITY: WHAT'S IMPORTANT FOR VASCULAR HEALTH IN CHILDREN?

HOPKINS, N., STRATTON, G., RIDGERS, N.D., GRAVES, L.E.F., FOWEATHER, L., CABLE, N.T., GREEN, D.J.

LIVERPOOL JOHN MOORES UNIVERSITY

**Background:** Vascular dysfunction is the earliest detectable manifestation of cardiovascular disease (CVD) and is a strong independent predictor of CV events. We have previously demonstrated both a cross sectional (Hopkins et al., 2009) and longitudinal (Hopkins et al., 2010) relationship between physical activity (PA) and vascular function in children. Some recent evidence suggests that sedentary behaviour (SB) is independently associated with CVD risk and mortality. This may lead to future public health campaigns that promote a reduction in SB rather than an increase PA. We therefore sought to determine the relationship between SB and vascular function in children. To this end we assessed basal associations between SB and vascular function, along with the relationship between changes in SB and vascular function. **Study Design and methods:** We studied 116 children (70♀:  $10.7 \pm 0.3$ ; 46♂:  $10.7 \pm 0.3$  yrs) on two occasions; in the summer (June) and late autumn (November). We assessed vascular function via flow-mediated dilation (FMD) using high resolution Doppler ultrasound. Sedentary behaviour was assessed using objective uni-axial accelerometry. Data was adjusted for age, maturation and physical activity level. **Results:** At baseline there were no significant differences between girls and boys. FMD, a preclinical marker of atherosclerosis, was not associated with SB in either group or in the cohort as a whole. Although FMD decreased significantly ( $10.0 \pm 4.3$  to  $7.9 \pm 3.9\%$ ,  $P < 0.001$ ) and SB significantly increased ( $499.1 \pm 103.5$  to  $559 \pm 81.6$  min/day,  $P < 0.001$ ) between the seasons, no relationship existed between changes in these variables. **Conclusions:** Our findings suggest that SB, and changes in SB, are not associated with vascular function in children. When taken with our previous findings which demonstrate a relationship between vascular function and PA, these results suggest that promotion of increased PA, rather than avoidance of SB, may yield the greatest results in terms of improving vascular health. **References** Hopkins N, Stratton G, Tinken TM, McWhannell N, Ridgers ND, Graves LEF, Cable NT, Green DJ (2009). Atherosclerosis 204: 244-249. Hopkins N, Stratton G, Tinken T, Ridgers N, Graves L, McWhannell N, Cable N, Green D (2010) Med Sci Sports Exerc 43 (2): 232-238.

## ACUTE INTERVAL AND CONTINUOUS MODERATE INTENSITY AEROBIC EXERCISE DOES NOT IMPROVE CAROTID ARTERIAL STIFFNESS IN POSTMENOPAUSAL WOMEN

HARRIS, E., RAKOBOWCHUK, M., KATARIA, A., BIRCH, K.M.

UNIVERSITY OF LEEDS

**Introduction** Postmenopausal women have greater arterial stiffness than premenopausal women due to the loss of oestrogen, increasing cardiovascular disease risk (2). Acute bouts of moderate intensity exercise improve arterial stiffness (1), with greater improvements produced after interval exercise (IE) when compared with continuous exercise (CE; 3). However, these sessions are rarely matched for duration, work completed and O<sub>2</sub> consumption and have not been studied in postmenopausal women. We designed a study that matched IE and CE for total work and duration and hypothesised that IE would exert greater improvements on carotid arterial vascular parameters than CE. **Methods** Eleven sedentary postmenopausal women ( $63 \pm 3$  years) performed a 30 min continuous moderate intensity exercise session at 80% of lactate threshold on a cycle ergometer. On a separate day, participants completed a work matched IE

session, (10s at a work rate equivalent to 90% VO<sub>2</sub>peak with 20s recovery repeated for 30 min). Carotid arterial stiffness measures were collected using ultrasound imaging and applanation tonometry before and at 20 minutes post exercise. Results An acute session of CE or IE did not improve carotid arterial stiffness parameters in postmenopausal women at 20 minutes post exercise, (Brachial SBP Pre CE:136±15 mmHg, Post CE:135±12 mmHg, Pre IE:138±19 mmHg, Post IE:134±15 mmHg, P=0.37; Carotid SBP Pre CE:126±11 mmHg, Post CE:121±11 mmHg, Pre IE:125±16 mmHg, Post IE:121±12 mmHg, P=0.84; Carotid Pulse Pressure Pre CE:43±9 mmHg, Post CE:40±9 mmHg, Pre IE:43±14 mmHg, Post IE:39±9 mmHg, P=0.61; Carotid delta cross-sectional area Pre CE:4.3±1.7 mm<sup>2</sup>, Post CE:4.4±1.1 mm<sup>2</sup>, Pre IE:4.4±1.7 mm<sup>2</sup>, Post IE:4.1±0.9 mm<sup>2</sup>, P=0.23; Carotid compliance Pre CE:0.10±0.05 mm<sup>2</sup>/mmHg, Post CE:0.11±0.02 mm<sup>2</sup>/mmHg, Pre IE:0.11±0.04 mm<sup>2</sup>/mmHg, Post IE:0.11±0.03 mm<sup>2</sup>/mmHg, P=0.71; Carotid distensibility Pre CE:0.003±0.001 mm/mmHg, Post CE:0.003±0.001 mm/mmHg, Pre IE:0.003±0.002 mm/mmHg, Post IE:0.003±0.001 mm/mmHg, P=0.23). Discussion An acute bout of moderate intensity aerobic exercise does not alter carotid arterial stiffness in postmenopausal women and is not any lower after IE when compared to CE. These findings do not support the hypothesis or previous studies. However, our study measured arterial stiffness in postmenopausal women, which unlike the individuals used in previous studies, is a population prone to higher arterial stiffness. Thus, postmenopausal women may require a higher exercise intensity to initiate vascular improvements. References 1 Kingwell, B.A. et al. (1997). *Am J Physiol* 273, H2186- H2191 2 Moreau, K.L. et al. ## ENDOTHELIAL FUNCTION IS IMPAIRED IN POLYCYSTIC OVARIAN SYNDROME AND CAN BE IMPROVED WITH EXERCISE TRAINING

SPRUNG, V.S.1, CUTHBERTSON, D.J.2, PUGH, C.J.A.1, AZIZ, N.3, KEMP, G.J.4, IRWIN, A.2, ADAMS, V.L.4, CABLE, N.T.1, ATKINSON, G.1, GREEN, D.J.1,5, JONES, H.1

1RISES, LIMU, 2DEPARTMENT OF OBESITY & ENDOCRINOLOGY, UHA, 3DEPARTMENT OF GYNAECOLOGY, LWH, 4MARIARC, UNIVERSITY OF LIVERPOOL, UK, 5SCHOOL OF SPORTS SCIENCE, EXERCISE & HEALTH, UWA, AUS.

Introduction Polycystic ovarian syndrome (PCOS) is associated with abdominal obesity, insulin resistance and elevated hepatic fat. This adverse cardiovascular disease (CVD) risk profile is associated with ~2 fold increased risk of coronary artery disease. Limited research exists regarding the cardiometabolic effects of exercise in PCOS, and its impact on endothelial function, an early indicator of CVD risk, has not been explored. We hypothesised that PCOS patients would exhibit decreased endothelial function when compared to matched controls and that an exercise intervention would improve endothelial function and reduce fat deposition in PCOS. Methods PCOS (n=9, age 27±2 yrs, BMI 30±2 kg/m<sup>2</sup>) and control (n=9, age 27±2 yrs, BMI 29±2 kg/m<sup>2</sup>) subjects were matched for age and BMI. Brachial artery endothelial function was assessed using flow mediated dilation (FMD). Visceral and subcutaneous fat was quantified by whole body magnetic resonance imaging and <sup>1</sup>H magnetic resonance spectroscopy determined hepatic fat. All PCOS women completed a 16-week supervised exercise program (93% exercise compliance), after which all assessments were repeated. Differences between PCOS and controls, and changes with exercise in the PCOS group were analysed using t-tests. Data are presented as mean±SE. Results FMD was impaired in PCOS compared to controls (7.1±1.1 vs 11.8±1.1%; P=0.02). FMD improved following exercise training (7.1±1.1 vs 10.3±0.8%; P=0.04) and was accompanied by a reduction in abdominal subcutaneous fat (12.0±1.6 vs 11.0±1.6 l; P=0.03). Cardiorespiratory fitness improved by 4.7 ml.kg<sup>-1</sup>.min<sup>-1</sup> (P=0.01) and waist circumference tended towards a reduction (98.2±4.5 vs 94.1±5.5 cm; P=0.09). Favourable effects were observed in hepatic fat, total subcutaneous fat, total and abdominal visceral fat, BMI, and body mass; however these reductions were not statistically significant. Discussion The novel finding of this study is that impaired endothelial function in PCOS patients can be improved by 45% with an exercise intervention. This was accompanied by a reduction in abdominal subcutaneous fat. These data suggest that the utilisation of exercise as a non-pharmacological management strategy has multiple therapeutic effects on CVD risk and the recurrent issue of abdominal obesity in this high risk patient group.

## CONDUIT ARTERY REMODELLING IN ELITE ATHLETES: INSIGHTS INTO LOCALISED AND SYSTEMIC ADAPTATIONS

ROWLEY, N.

LIVERPOOL JOHN MOORES UNIVERSITY

Rowley N.J.1, Thijssen D.1,2, Dawson E.1, Cable T.1, George K.1, Whyte G.1, Green D.J.1,3 1:LJMU(Liverpool, UK), 2:RUMC(Nijmegen, Netherlands), 3:UWA(Perth, Australia) Introduction The effects of exercise on conduit artery structure are directly relevant to explaining the cardiovascular benefits of exercise. However, the impact of training on arterial remodelling in humans, particularly the effect of different haemodynamic stimuli, has not been fully characterised. Methods To examine localised versus systemic effects of chronic exercise training on arterial wall thickness (WT) and diameter, we recruited distinct groups of elite athlete including squash players (Sq n=13), lower limb endurance athletes (LE, n=13), canoe paddlers (CP, n=12) and matched healthy inactive controls (C, n=16). Spinal cord injured patients (SCI, n=9) were also included. Brachial and superficial femoral artery (SFA) characteristics were assessed in all groups using high resolution duplex ultrasound, with dominant and non-dominant brachial arteries also assessed in the Sq group. Results Brachial diameters were significantly larger in dominant versus non-dominant limb of Sq at rest (4.9±0.5 vs 4.3±0.4mm, P<0.05) and in response to a dilator stimulus (5.5±0.5 versus 4.8±0.4, P<0.05). Similar effects were apparent in peak blood flow responses (1118±326 vs 737±219ml/min, P<0.01). In addition, CP (4.9±0.8) and Sq (4.9±0.5) possessed significantly larger brachial diameters than C (4.1±0.5, P<0.05). LE and SCI subjects' brachial diameters did not differ significantly from C. These findings suggest that both conduit and resistance artery remodelling of diameter occurs in response to localised effects of training. Athletic groups demonstrated lower WT than C and SCI subjects across all arteries studied (carotid: Sq 510±60µm, LE 530±110, CP 560±70µm vs SCI 660±70µm, C: 620±70µm, all P<0.05; brachial: Sq 239±100, LE 270±80, CP 370±110 vs SCI 488±70, C 520±100, all P<0.01; SFA: Sq 480±40, LE 490±60, CP 480±70 vs SCI 580±60, C 630±120, all P<0.01). In contrast to the arterial diameter data, no differences in WT were evident between dominant and non-dominant limbs of the Sq group (239±100 vs 234±133). These findings suggest that remodelling of the conduit artery wall occurs systemically in response to exercise training in humans. Discussion This is the first study in humans to attempt to uncouple localised and systemic effects on artery size and WT in response to exercise. We provide evidence for systemic effects of exercise training on arterial WT, possibly mediated by the impact of training on arterial pressure. In contrast, the impacts of exercise on conduit and resistance artery cross sectional size appear to be dictated more by localized, and possibly shear-stress mediated, effects. These findings have implications for our understanding of the anti-atherogenic effects of exercise training in humans.

### EFFECT OF DEGREE OF 6-MONTH WEIGHT-LOSS SUPPORT PROGRAM ON ARTERIAL STIFFNESS: A RANDOMIZED CONTROLLED TRIAL IN MIDDLE-AGED OVERWEIGHT HUMANS

TANABE, Y., NAKATA, Y., YOSHIZAWA, M., AJISAKA, R., MAEDA, S.

UNIVERSITY OF TSUKUBA

**BACKGROUND:** Increase in arterial stiffness has been identified as powerful and independent risk factor for cardiovascular disease. Arterial stiffness in obese humans is higher than that in normal weight humans. Weight reduction by lifestyle modification, i.e., low-calorie diet and/or habitual exercise, decreases in arterial stiffness in obese subjects. However, the effect of degree of weight-loss support on arterial stiffness in obese subjects has not yet been clarified. Therefore, we investigated whether degree of weight-loss support affects arterial stiffness in middle-aged overweight humans. **METHODS:** A total of 188 middle-aged overweight men and women participated in a 6-month randomised controlled trial with body weight as the primary outcome measure ( $51 \pm 7$  years, BMI:  $29.0 \pm 3.2$  kg/m<sup>2</sup>). Participants were randomly assigned to the control (CON, n=63), moderate intervention (MI, n=62), and intensive intervention (II, n=63) groups. We provided a single motivational lecture on weight loss to all 3 groups, educational materials (textbooks, notebooks, and a pedometer) to groups MI and II, and group-based support programme to the II group. Before and after the 6-month intervention, body weight and arterial stiffness were measured. The arterial stiffness was evaluated by brachial-ankle pulse wave velocity (baPWV). One participant in MI group was excluded for the incomplete evaluation of baPWV. **RESULT:** After the 6-month intervention, the participants decreased their body weight by  $2.9 \pm 4.1$  kg,  $4.7 \pm 4.0$  kg, and  $7.7 \pm 4.1$  kg in groups CON, MI, and II, respectively with intention-to-treat analysis. All between-group differences were significant. Although baPWV significantly decreased in all groups, there were no significant differences in the changes of baPWV among the groups. **CONCLUSION:** The present study demonstrates that lifestyle modification decreases body weight and arterial stiffness in middle-aged overweight humans. However, the degree of weight reduction or weight-loss support does not affect arterial stiffness. Therefore, mild weight loss may be sufficient to improve arterial stiffness in middle-aged overweight humans. This work was supported by the JA Ibaraki Public Welfare Federation and Grants-in-Aid for Scientific Research 21300234 and 21650179 from Japan Society for the Promotion of Science.

### AEROBIC EXERCISE TRAINING INCREASES MIDDLE CEREBRAL BLOOD FLOW VELOCITY IN POSTMENOPAUSAL WOMEN

AKAZAWA, N.1, CHOI, Y.1, MIYAKI, A.1, TANABE, Y.1, SUGAWARA, J.2, AJISAKA, R.1, MAEDA, S.1

1)UNIVERSITY OF TSUKUBA, 2)NATIONAL INSTITUTE OF ADVANCED INDUSTRIAL SCIENCE AND TECHNOLOGY (AIST)

**Background:** It is known that cerebral blood flow declines with aging. As low cerebral blood flow is associated with cognitive decline, cerebral hypoperfusion may precede and possibly contribute to dementia. Aerobic exercise training increases cognitive function, brain volume, and the number of cerebrovascular vessel in older subjects. Recently, a cross-sectional study demonstrates that regular aerobic exercise elevates middle cerebral blood flow velocity. To provide direct evidence that regular aerobic exercise increases middle cerebral blood flow velocity, the present study investigated whether aerobic exercise training increases middle cerebral blood flow velocity in postmenopausal women. **Methods:** Twenty-two healthy postmenopausal women (53-77 yr old) were assigned to the exercise group (n=12) and the control group (n=10). The exercise group completed an 8-week moderate aerobic exercise intervention (60-75% of maximal heart rate, 30-45 min/day, 3-5 days/week). Before and after intervention, we measured middle cerebral blood flow velocity with Transcranial Doppler ultrasonography. **Results:** There was no difference in baseline middle cerebral blood flow velocity and most other key dependent variables between the groups. Maximal oxygen uptake in the exercise group increased after exercise intervention. Middle cerebral blood flow velocity increased significantly in the exercise group, whereas no such change was observed in the control group. **Conclusion:** We demonstrated that aerobic exercise training increases middle cerebral blood flow velocity in postmenopausal women. This finding suggests that regular aerobic exercise may depress the decrease in aging-induced cerebral blood flow. This work was supported by Grants-in-Aid for Scientific Research 21300234 and 21650179 from Japan Society for the Promotion of Science.

### HEART RATE COMPLEXITY AND VARIABILITY AFTER ENDURANCE, STRENGTH AND COMBINED ENDURANCE AND STRENGTH TRAINING IN AGEING WOMEN

KARAVIRTA, L., COSTA, M.D., GOLDBERGER, A.L., MIETUS, J.E., TULPPU, M.P., LAAKSONEN, D.E., NYMAN, K., KESKITALO, M., HÄKKINEN, A., HÄKKINEN, K.

**HEART RATE COMPLEXITY AND VARIABILITY AFTER ENDURANCE, STRENGTH AND COMBINED ENDURANCE AND STRENGTH TRAINING IN AGEING WOMEN** Karavirta, L. 1, Costa, M.D. 2, Goldberger, A.L. 2, Mietus, J.E. 2, Tulppo, M.P. 3, Laaksonen, D.E. 4, Nyman, K. 5, Keskitalo, M. 1, Häkkinen, A. 1,5, Häkkinen, K. 1 1 University of Jyväskylä (Jyväskylä, Finland), 2 Harvard Medical School (Boston, MA, USA), 3 Verve Research (Oulu, Finland), 4 Kuopio University Hospital and University of Eastern Finland (Kuopio, Finland), 5 Central Finland Central Hospital (Jyväskylä, Finland) **Introduction** Age-related structural and functional changes in the cardiovascular system decrease the complexity of heart rate (HR) control, leading to impaired ability to adapt to physiological stress (Lipsitz 2004). In the present study, training mode-specific effects of endurance and strength training and their combination on HR complexity and HR variability were examined in ageing women. **Methods** 90 previously untrained female volunteers aged 40 to 65 years completed a 21-week progressive training period of either endurance training twice a week, strength training twice a week, a combination of endurance and strength training on alternate days with a total of four times per week, or served as controls. Training was fully supervised and carefully controlled. Training adaptations of physical performance were quantified as maximal aerobic power output in a bicycle ergometer test to exhaustion and as one repetition maximum (1RM) in dynamic leg press. Short-term HR dynamics were determined at supine rest and during submaximal steady state exercise using standard time and frequency domain measures as well as complexity index (CI) derived from multiscale entropy analysis (Costa et al. 2002). **Results** Endurance training led to increases in CI and time and frequency domain measures of HR variability ( $P < 0.01$ ) when measured during exercise, whereas strength training alone or combined endurance and strength training did not produce significant changes in HR dynamics. Endurance training adaptations mainly occurred during the first ten weeks of training. At rest no training-induced changes were observed. In terms of physical performance, endurance and strength training led to expected training mode-specific improvements ( $P < 0.001$ ) in maximal aerobic power output and 1RM of leg press, respectively. **Discussion** The present findings emphasise the potential of endurance training to increase the complexity and variability of HR in ageing women. Regardless of the larger training volume in the combined training group, simultaneous training for endurance and strength did not produce further benefits for HR control but rather, might have impaired the endurance training-induced adaptations. **References** Lipsitz LA (2004). *Sci Aging Knowl Environ* 2004(16), pe16. ## SPONTANEOUS BAROREFLEX CONTROL OF HEART RATE DURING ACTIVATION OF THE MUSCLE METABOREFLEX IN THE FOREARM AND CALF IN HUMANS

WATANABE, K.1, ICHINOSE, M.2, FUJII, N.3, TSUJI, B.1, SUGIHARA, A.1, NIWA, T.1, NISHIYASU, T.4

1: UNIVERSITY OF TSUKUBA, 2: MELII UNIVERSITY, 3: JSPS FELLOW, 4: UNIVERSITY OF TSUKUBA

**Introduction** We previously suggested that, in humans, muscle metaboreflex (MMR) activation induced by postexercise muscle ischemia (PEMI) increases cardiac parasympathetic tone (Nishiyasu et al., 1994) as well as the sensitivity of the spontaneous baroreflex control of heart rate (SBRS) (Ichinose et al., 2007). The aim of the present study was to test the hypothesis that changes in cardiac autonomic tone and SBRS induced by PEMI following isometric handgrip and plantar flexion exercises are not identical. **Methods** Eleven healthy subjects performed 90-s isometric handgrip (FOREARM) and plantar flexion (CALF) exercises at 30% maximal voluntary contraction (MVC). Subjects also performed an isometric plantar flexion exercise at 70% MVC, which elicited a PEMI-induced pressor response that matched the response elicited by FOREARM (CALF-matched). Each bout of exercise was followed by a 5-min period of imposed PEMI. We estimated cardiac autonomic tone using spectral analysis of beat-to-beat variation in the R-R interval, while SBRS was evaluated using transfer function analysis of systolic arterial pressure and R-R interval. **Results** Although mean arterial pressure (MAP) during PEMI was higher than during rest in all trials, MAP during PEMI was lower in CALF than FOREARM, and there was no difference between CALF-matched and FOREARM. Also during PEMI, cardiac parasympathetic tone and SBRS were higher in FOREARM than during rest, but did not differ from rest in CALF or CALF-matched. **Discussion** Consistent with an earlier study (Carrington et al., 2004), we found that PEMI-induced pressor responses after forearm exercises were greater than after calf exercises of the same relative intensity. We also confirmed that PEMI increases cardiac parasympathetic tone and SBRS following forearm exercise. That was not the case with PEMI after calf exercise, even though the relative intensity of the exercise or the degree of the PEMI-induced pressor response was comparable to the forearm exercise. This suggests the effects of MMR on cardiac autonomic nervous system and arterial baroreflex functions differ, depending upon whether the MMR is engaged in the forearm or calf muscles. **References** Carrington CA, Fisher JP, Davies MK, White MJ (2004). ## A COMPARISON BETWEEN GOW HEART RATE MONITOR AND A COMMERCIAL ECG FOR MEASUREMENT OF HEART RATE VARIABILITY DURING EXERCISE.

ALIS, R.1,2, ROMAGNOLI, M.1,2, GUILLÉN, J.1, BLANCH, A.1, BASTERRA, J.1, GUILLÉN, S.3

CATHOLIC UNIVERSITY VALENCIA

**Introduction** Heart rate variability (HRV) is the oscillation of the time interval between consecutive heartbeats (Task Force 1996). It's a useful tool that provides information of the autonomic regulation of cardiac function (Buchheit and Gindre 2006). Its usefulness is recognized in many areas, from cardiology (Karp, Shiyovich et al. 2009), to the sports field (Hedelin, Wiklund et al. 2000; Mourrot, Bouhaddi et al. 2004; Cottin 2006). In this study we try to compare HRV data from a smart textile system for recording heart rate variability (GOW) and an electrocardiogram machine (LYNX® signal conditioner) commonly used in hospitals, during a continuous cycling test. **Methods** 6 cardiology patients performed a cycling test at stable intensity, heart rate variability data was recorded by the two systems during the test. 3' RR segments were taken to compare time intervals between beats and HRV variables, using Bland-Altman analysis and intraclass correlation coefficient (ICC). **Results** Limits of agreement (LoA) were stable on RR intervals around 4 ms (Widest LoA: -7.979 to 7.457; Tightest LoA: -4.351 to 3.553; Medium LoA, -4.39 to 4.90). HRV variables present ICC to ensure interchangeability of the methods in 5 of 7 variables. However RMSSD, HF and SD1 have large LoA. **Discussion** Time intervals between heartbeats recorded by two methods were similar, LoA was about the difference on sampling times (1ms for Lynx and 4 ms for GOW) (Weippert, Kumar et al. 2010). Correlation on HRV variables between the two methods is good except for RMSSD, HF and SD1, related to short-term variability (Task Force 1996), and sensitive to different sampling times (Gamelin, Berthoin et al. 2006). We conclude that both systems have excellent agreement in the register of RR intervals, but they are not so great for HRV variables related to the short time. **References** Buchheit, M. ## ELEVATION BLOOD FLOW IN COMMON CAROTID ARTERY WITH AEROBIC FITNESS IN ELDERLY WOMEN

HIRASAWA, A., SATO, K., OUE, A., NAKAMURA, I., SADAMOTO, T.

JAPAN WOMEN'S COLLEGE OF PHYSICAL EDUCATION

**Introduction** It is known that cerebral blood flow (CBF) declines with aging in sedentary adults. Previous studies suggested that habitual aerobic-endurance exercise elevates the resting CBF in healthy male adults (Ainslie et al. 2008) and middle-aged monkeys (Rhyu et al. 2010). However it has not yet been examined in elderly women whether aerobic fitness level affects the CBF. The aim of the present study was to determine the relationship between CBF and aerobic fitness in elderly women over 65 years old. **Methods** The subjects comprised 92 healthy elderly women (range 66 to 88 years). The blood flow in common carotid artery (CCA) measurements were performed with subjects in the spine position following 3-min of rest. The right CCA blood flow velocity and mean vessel diameter were measured using a Doppler Ultrasound system (Vivid-e, GE Healthcare, Japan). The CCA blood flow volume was calculated  $\pi \times (\text{mean vessel diameter} / 2)^2 \times \text{blood flow velocity} \times 60$ . The ratio of mean arterial pressure to CCA blood flow volume was to calculate as index of cerebrovascular resistance. In addition, aerobic fitness was measured using a 6-min walking distance test. Subjects were divided into either high (FIT) or low (UNFIT) aerobic fitness groups based on a walk distance result of 6-min walking distance test. FIT and UNFIT of mean walking distance was  $547 \pm 27$  m (N=45) and  $421 \pm 88$  m (N=47), respectively. **Results** CCA blood flow velocity was not different FIT and UNFIT. CCA mean vessel diameter in the FIT was significantly larger than in the UNFIT group ( $7.0 \pm 0.7$  vs.  $6.7 \pm 0.7$  mm,  $p < 0.05$ ). CCA blood flow volume in the FIT was significantly higher than in the UNFIT group ( $438 \pm 104$  vs.  $381 \pm 87$  ml/min,  $p < 0.05$ ). On the other hand, mean arterial pressure in the FIT was significantly lower than in the UNFIT group ( $94 \pm 13$  vs.  $99 \pm 16$  mmHg,  $p < 0.05$ ). Therefore, cerebrovascular resistance was significantly lower in the FIT than in the UNFIT group ( $0.22 \pm 0.06$  vs.  $0.27 \pm 0.07$  mmHg/ml.min<sup>-1</sup>,  $p < 0.01$ ). **Discussion** In elderly women, we found that CCA blood flow volume in the high aerobic fitness subjects was significantly higher as compared with

low aerobic fitness subjects. The significant low cerebrovascular resistance in high aerobic subjects probably reflects a lower vasoconstriction in the brain vasculature. These results suggest that habitual aerobic-endurance exercise in elderly women also contributes to reduce the risk of cerebrovascular disease. References Ainslie PN et al. *J Physiol*, 586, 4005-4010, 2008. Rhyu IJ et al. *Neuroscience*, 167, 1239-1248, 2010.

## THE EFFECTS OF SLEEP AND INTERMITTENT EXERCISE ON VASCULAR FUNCTION IN HUMANS

JONES, H., LEWIS, N.C.S.1, GREEN, D.J.1,2, ATKINSON, G.1.

1 RESEARCH INSTITUTE FOR SPORT AND EXERCISE SCIENCES, LIVERPOOL JOHN MOORES UNIVERSITY; 2 SCHOOL SPORTS SCIENCE, EXERCISE AND HEALTH (UWA, AUSTRALIA)

**Introduction** An effect of intermittent exercise on vascular function is apparent in the afternoon, but not the morning (Jones et al., 2010). It is unclear whether this is due to a true diurnal effect (i.e. mediated by the body clock), or the impact of prior sleep on the vasculature. We therefore examined the effect of prior sleep on vascular endothelial function before and after an acute bout of intermittent exercise undertaken in the morning and afternoon. **Methods** Nine healthy, physically active males (aged 27±9 yrs) completed three 10-min bouts of cycling at 60% maximum work-rate, separated by 10-min rest periods. The exercise was performed on separate days beginning at either 08:00 or 16:00 h. To assess the impact of prior sleep, 4-hours of nocturnal or daytime sleep preceded the 08:00 and 16:00 h protocols. Ten minutes before and after each exercise bout, brachial artery vascular function was assessed using the flow-mediated dilation technique (FMD). Heart rate (HR), systolic and diastolic blood pressure (BP) was also monitored continuously. Data were analysed using general linear models and Newman-Keuls multiple comparisons and presented as mean±SD. **Results** When prior sleep was controlled, no morning vs afternoon difference in FMD was found at rest (6±3 vs 7±2%) or following exercise (9±4 vs 9±4 %; P=0.68). Baseline artery diameter was significantly greater in the morning compared with the afternoon (4.35±0.51 vs 4.20±0.54 mm; P=0.05) but was not affected by exercise (P=0.16). HR was 4±4 beats/min higher in the morning (P=0.05) and also 11±9 beats/min higher after exercise compared to before (P=0.01). Systolic and diastolic BP were not affected by sleep or exercise (P>0.10). **Discussion** A bout of sleep in the afternoon abolished the effect of exercise on vascular function by reducing resting FMD to similar values observed in the morning. This finding suggests that the diurnal variation in resting FMD is explained by the impact of prior sleep in the supine position on the vasculature, rather than an endogenous influence of the human body clock. As vascular endothelial function is a strong predictor of cardiovascular events, this data infers that classically observed increase in cardiovascular events in the morning is related to the prior effect of sleep. **References** Jones et al., (2010) *AJP-Regul Inter Comp Physiol* 298: R427-432.

### PP-PM03 Oxidative Stress

## INFLUENCE OF SPORT EXPERIENCE TO APPEARANCE OF OXIDATIVE STRESS IN MALE JUDOKAS

TRIVIC, T., DRID, P., OBADOV, S.

FACULTY OF SPORT AND PHYSICAL EDUCATION

**Abstract Introduction** Physical activity can result in a number of metabolic changes in the body. To determine, whether endurance training induce oxidative stress in athletes with different sport experience (same age), twenty judokas were studied in four week training program. Subjects were divided into 2 groups (1: below-average training experience between 4.0 and 6.0 years, 2: average training experience between 6.0 and 8.5 years). The aim of the study was to compare biomarkers of oxidative stress and total antioxidant activity in male judokas, different sport experience. **Methods** Blood samples were taken from the antecubital vein inside of the elbow into plain vacutainer tubes. First blood samples were taken from all subjects, in the morning at 07:00pm one day before training program. Second blood samples were taken one day after training program, which followed a period of four weeks. The following parameters were measured: superoxide dismutase (SOD), glutathione reductase (GSH-R), glutathione peroxidase (GSH-Px), catalase (CAT) and total antioxidant activity (TAS). **Results** Results of research has shown that applied endurance training program induced a statistically significant decrease in TAS (p <0.05) in judokas with lower sport experience, in compared with judokas with higher sport experience, after the final measurement. Also, statistically significant higher value of CAT and GSH-R were noted in athletes with lower sport experience. **Discussion** Result of training in booth aerobic (Chavi et al., 2007) and anaerobic activities (Bailey et al., 2007) induce elevated oxidative processes. Endurance athletes consume large amounts of oxygen which increases the production of reactive oxygen species (ROS) and leads to oxidative stress (Williams et al., 2006). Results of this research suggest that oxidative status parameters are adequately changeable in judokas, with different sport experience. Therefore, athletes with lower sport experience, require higher intakes of antioxidants to defend against increased oxidative stress. Currently, from obtained results it is clear that judokas with lower sport experience have potential to result in increased free radical production, which may or may not result in acute oxidative stress. **References** Bailey DM, Lawrenson L, McEneny J, Young IS, James PE, Jackson SK, Henry RR, Mathieu-Costello O, McCord JM, Richardson RS. ## INFLUENCE OF SPORTS MASSAGE ON IMMUNOLOGICAL PARAMETERS AFTER HIGH-INTENSITY INTERVAL TRAINING

HALPER, B., HOFMANN, M., VIDOTTO, C., BACHL, N., TSCHAN, H., WESSNER, B.

UNIVERSITY OF VIENNA, CENTRE FOR SPORTS SCIENCE AND UNIVERSITY SPORTS

**Introduction** Sports massage is frequently used by athletes to improve recovery from strenuous exercise. Data from randomized controlled trials provide moderate evidence for the efficacy of massage therapy to facilitate recovery from repetitive muscular contractions (Best et al., 2008). It is unclear whether sports massage is able to affect the immunological response after high-intensity interval training. **Methods** This study was planned as a randomized, single-blind, controlled crossover intervention study with a wash-out period of 4 weeks. Twelve male, active subjects (age: 25±2 years, BMI:22.6±2.7kg/m<sup>2</sup>) were included after obtaining written informed consent. Allocation to one of the study groups (A:massage-control; B:control-massage) was performed using an online generated randomization list. The exercise consisted of high-intensity interval training (7min warm up; 4x4min at 90-95% and 50% iHRmax, respectively; 7min cool down). After the exercise the participants received a standardised massage on legs and back or rested for 35min (control). Blood samples were

taken before exercise (t0), directly after exercise (t1), after intervention (t2), one hour (t3) and 22 hours (t4) after intervention. Leukocyte counts as well as plasma IL-1ra, IL-6, sIL-6R, IL10, TNF- $\alpha$ , sTNF- $\alpha$ R1, CK and myoglobin concentrations were measured. Statistical differences between time points, groups and interaction effects were determined using repeated measured ANOVA. Results There was a significant increase in leukocyte counts (up to 120% for granulocytes,  $p < 0.001$ ), muscle damage markers (myoglobin+120%,  $p < 0.001$ ), and cytokines (up to 3-fold for IL-10,  $p < 0.001$ ) after the exercise. Almost all parameters showed their maximum increase directly after exercise (t1) with the exemption of IL-1ra and CK concentrations and granulocyte counts which peaked at later time points (t3 and t4). Sports massage did not affect any of the measured parameters. Additionally, we did not detect any time x group interactions. Discussion In our study we could confirm previous results showing a challenge of the immune system by strenuous exercise (Nieman, 1997, Suzuki et al., 2000). However, sports massage as recovery measure did not affect these parameters. This is slightly in contrast to a study by Arrayo-Morales et al. (2009) showing higher secretion rates of salivary IgA after massage recovery intervention. In conclusion sports massage might improve subjective parameters and delayed onset of muscle soreness but is not able to improve immunological parameters. ## EFFECTS OF ACUTE SLEEP DEPRIVATION ON EXERCISE TOLERANCE AND STRESS HORMONES DURING MAXIMAL EXERCISE

KONISHI, M.1, TAKAHASHI, M.1, KIM, H.1, TABATA, H.1, ENDO, N.1, NUMAO, S.1, TAKAGI, S.2, YAMADA, Y.1, MIYASHITA, M.1, MIDORIKAWA, T.3, SUZUKI, K.1, SAKAMOTO, S.1

1: WASEDA UNIVERSITY, 2: TOKYO MEDICAL UNIVERSITY, 3: J.F. OBERLIN UNIVERSITY

Introduction Exercise is beneficial for health, but there is a risk of sudden death during strenuous exercise (Boraita, 2002). Sleep deprivation is associated with cardiac arrest (Murayama, 1994). Overworks of the circulatory system and exposure to stress under sleep deprivation may contribute to cardiac arrest. However, the effects of sleep deprivation on the circulatory system and stress responses during exercise are unclear. The purpose of this study was to investigate the effects of 34 hours of sleep deprivation on exercise tolerance and stress hormones during maximal exercise. Methods Ten healthy young males completed two, 2-day trials (i.e. control and sleep deprivation trials) separated by more than five days each. For the control trial, participants were allowed normal sleep from 23:00 to 7:00; for the sleep deprivation trial, they did not sleep for 34 hours. These experimental trials were performed under supervision by the investigators. On both trials, venous blood samples were collected at 9:00, 13:00, 17:00 (before exercise stress tests) and immediately after exercise stress tests to determine plasma adrenaline, noradrenaline, adrenocorticotrophic hormone (ACTH) and cortisol concentrations. Exercise tolerance testing was performed on a treadmill until exhaustion by ramp protocol at 17:00 on day 2. Oxygen uptake and heart rate were measured at rest and during exercise. Results ACTH concentrations at 9:00 and 13:00 were significantly higher in the sleep deprivation trial than the sleep trial on day 2 (9:00: Sleep trial,  $35.3 \pm 18.5$ ; Sleep deprivation trial,  $48.6 \pm 17.7$ , 13:00: Sleep trial,  $24.2 \pm 6.3$ ; Sleep deprivation trial,  $30.1 \pm 7.3$  pg/ml,  $P < 0.05$ ). No differences were found in the other stress hormones at rest and immediately after exercise between trials. Oxygen uptake during exercise was tended to be higher by sleep deprivation ( $P = 0.08$ ). Heart rate during exercise was significantly decreased by sleep deprivation ( $P < 0.05$ ). Discussion The present study indicated an increase in ACTH concentrations at rest, a slightly increase in oxygen uptake and a decrease in heart rate during maximal exercise in the sleep deprivation trial. These data suggest that sleep deprivation induces ACTH secretion at rest and impairs exercise tolerance during exercise. References Boraita A. (2002). Rev Esp Cardiol, 55, 333-336. Murayama M. ## EFFECTS OF RESISTANCE AND AEROBIC EXERCISE TRAINING ON PROINFLAMMATORY CYTOKINES

NIKSERESHT, M.

EXERCISE PHYSIOLOGY

Introduction Elevated levels of inflammatory mediators have been associated with an increased risk and severity of chronic disease. Atherosclerosis and coronary artery disease are associated with greater levels of interleukin (IL)-6 and tumor necrosis factor (TNF)- $\alpha$  (Larsson et al., 2005). Furthermore, the purpose of the present study was to determine the effects of 10 wk of resistance and aerobic exercise training on interleukin-6 (IL-6), interleukin-1 $\beta$  (IL-1 $\beta$ ) and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ). Further, to determine pretraining and posttraining associations between alterations of IL-6, IL-1 $\beta$  and TNF- $\alpha$  with body composition. Methods A sample of 29 sedentary males (age (mean  $\pm$  SD) =  $31.7 \pm 8.1$  yr, BMI =  $29.3 \pm 4.3$  kg / m<sup>2</sup>) were assigned to a resistance group (n = 9), an aerobic group (n = 11) and a control group (n = 9). Before and after intervention, subjects were involved in muscular strength and aerobic fitness, measurements and further provided a resting fasted venous blood sample for measures of IL-6, IL-1 $\beta$  and TNF- $\alpha$ . The resistance and the aerobic groups completed a respective 10-wk supervised and periodized training program, whereas the control group maintained sedentary lifestyle and dietary patterns. Results Both exercise training programs did not reduce in IL-6, IL-1 $\beta$  and TNF- $\alpha$ . Compared with the control group, the aerobic and resistance groups exhibited significant ( $P \leq 0.05$ ) improvements in VO<sub>2</sub> max and significant reductions in body fat percentage and waist to hip ratio. Compared with the aerobic and the control groups, the resistance group significantly ( $P \leq 0.05$ ) improved upper (27.6%) and lower (39.8%) body strength. Discussion 10 wk of resistance and aerobic exercise training in sedentary disease-free males did not affect elevated baseline IL-6, IL-1 $\beta$  and TNF- $\alpha$ , and this is consistent with data obtained by Donges C.E, et al. (2009), that was shown after the 10-wk exercise training period, the IL-6 concentration of both the exercise groups and the control group remained unchanged. On the other hand, Kohut M.L et al. (2006), have observed that 10 months an aerobic exercise intervention can significantly reduce serum inflammatory mediators. It has been suggested that to reduce proinflammatory cytokines, the exercise training have to complete for more than a few months. References Larsson, P.T., Hallerstrom, S., Rosfors, S., Wallen, N.H. (2005). Int. Angiol. 24, 43-51. Cheyne E. Donges, Rob Duffield, and Eric J. Drinkwater. (2009). Medicine & Science in Sports & Exercise, 42, 2: 304-313. Kohut M.L, D.A. McCann, D.W. Russell, D.N. **Introduction** Oxidative stress and chronic inflammation are mediators of several diseases such as cancer, cardiovascular disease and diabetes. A previous study has shown that oxidative stress or pro-inflammatory cytokines increase with age (Ferrucci et al., 2005). Another study has reported that aerobic exercise training decreases oxidative stress and pro-inflammatory cytokines in older men (Fatouros et al., 2004). However, there is no definitive evidence for the effects of daily physical activity on oxidative stress and various cytokines. The purpose of this study was to examine the relationship between the amount of physical activity and oxidative stress markers and inflammatory cytokines in older adults. **Methods** Total of 29 older adults (aged  $70.1 \pm 5.2$  years, mean  $\pm$  SD; 17 females and 12 males) were analysed in the cross-sectional design. Prior to the blood collection, participants were asked to wear an uniaxial accelerometer for 4 consecutive weeks for the determination of physical activity status. After a 48-h period of physical activity avoidance and a 10-h overnight fast, fasting venous blood samples were obtained from each participant. Results Fasting plasma derivatives of reactive oxygen metabolites (d-ROMs) concentrations were negatively correlated with the amount of physical activity ( $r = -0.488$ ,  $P < 0.01$ ). Fasting plasma biological antioxidant potential (BAP) concentrations were positively correlated with the amount of physical activity ( $r = 0.607$ ,  $P < 0.01$ ). Moreover, fasting plasma d-ROMs concentrations were tend to be negatively correlated with fasting plasma BAP concentrations ( $r = -0.320$ ,  $P < 0.1$ ). There were no associations between physical activity and other oxidative stress markers (superoxide dismutase, catalase, glutathione peroxidase) or cytokines (IL-6, IL-8, IL-10, IL-1 $\beta$ , thioredoxin, TNF- $\alpha$ , myeloperoxidase, calprotectin and neutrophil gelatinase-associated lipocalin). **Discussion** This study shows that regular physical activity may provide a protective effect on oxidative stress by increasing total antioxidant capacity (i.e. estimated by the concentrations of BAP) in older adults, but no association was observed between regular physical activity and several cytokines. **References** Fatouros IG, Jamurtas AZ, Villiotou V, Pouliopoulou S, Fotinakis P, Taxildaris K, Deliconstantinos G. **Introduction** Sports engagement includes upregulation of many cell processes and physiological functions including upregulation of the antioxidant defence system (ADS). It was previously shown that well trained subjects have more efficient ADS compared with sedentary subjects (Finaud et al. 2006; Fisher-Wellman and Bloomer 2009), however those studies compared only the basal (rest) levels of pro/antioxidants in blood of athletes and non-athletes. Thus, we sought to investigate the effects of acute maximal intensity exercise on pro/antioxidant response in both athletes and non-athletes and to find correlations between morphofunctional characteristics of subjects and parameters of redox homeostasis. **Methods** 58 young handball players and 19 non-athletes were subjected to body composition analysis, measuring of maximal oxygen consumption and blood sampling immediately before and after maximal progressive exercise test. Blood samples were used for redox state analysis which included measurement of nitric oxide (estimated through nitrites), superoxide anion radical, hydrogen peroxide, lipid peroxidation (estimated through thiobarbituric reactive substances), superoxide dismutase activity, catalase activity and glutathione levels. Results In rest, athletes had significantly higher superoxide dismutase activity, higher glutathione levels and lower levels of index of lipid peroxidation compared with non-athletes. Maximal exercise test induced statistically significant rise of superoxide anion radical and hydrogen peroxide levels in non-athletes, while nitrite levels decreased both in athletes and non-athletes. Athletes also had decreased catalase activity after exercise. After exercise, athletes had significantly lower levels of superoxide anion radical compared with non-athletes. Significant correlations between morphofunctional (fat %, muscle %, aerobic power) and redox parameters were found. **Discussion** The initial hypothesis that athletes would have not only higher activity of antioxidants in rest, but that the extent of redox disturbance induced by maximal progressive exercise test would be lower in athletes compared with non-athletes was confirmed in this study. The results of our study prove that regular exercise training leads towards positive adaptations that alleviate the risk of oxidative stress in athletes, both during training sessions and during non-exercise related conditions. Sports engagement and physical fitness are important factors in inducing desirable changes in redox status. **References** 1. Finaud J, Lac G and Filaire E. (2006). *Sports Med*, 36, 327-358. 2. **Introduction:** Studies suggest that oxidative stress plays a major role in the in the pathogenesis of both types 1 and 2 diabetes mellitus (Sato et al., 1979). Abnormally high levels of free radicals and the simultaneous decline of antioxidant defense mechanisms can lead to damage of cellular organelles and enzymes and increased membrane lipid peroxidation. However It has been suggested that regular exercise might improve the antioxidant defense capacity against the oxidative stress (Radak et al., 2008). Therefore, the present study was designed to investigate whether resistance training is an effective form of exercise for managing oxidative stress biomarkers in the pancreas of rats after neonatal alloxan administration. **Methods:** Alloxan was injected in newborn rats at 6 days of age (250 mg/kg bw). At 28 days of age, the animals were divided into alloxan (A), control (C), trained alloxan (TA) and trained control (TC) groups. The resistance training consisted of 4 series of 10 jumps in the water, with a 1 min interval between them, while supporting a load of 50% of b.w, during 12 weeks. The animals were killed for analysis of pancreas lipid peroxidation markers concentration (substances that react to the barbituric acid – TBARS), and antioxidant enzymes activity (Superoxide dismutase (SOD) and Catalase) in the pancreas. Results: At 28 days of age the total area under the serum glucose (mg/dLx120min) curve during glucose tolerance test (GTT) was higher (t test,  $p < 0.05$ ) in alloxan rats than in controls (A:  $18138 \pm 1992$ , C:  $14792 \pm 624$ ). No difference between the groups (two-way ANOVA,  $p < 0.05$ ) was observed in TBARS content as well in SOD and Catalase activity between the groups: TBARS (nmol of mda/mg): TC:  $0.880 \pm 0.466$ , TA:  $0.682 \pm 0.226$ , C:  $0.875 \pm 0.397$ , A:  $0.980 \pm 0.620$ ; SOD (U/100mg): TC:  $2.39 \pm 0.95$ , TA:  $2.09 \pm 0.80$ , C:  $1.92 \pm 0.70$ , A:  $1.89 \pm 0.75$  and Catalase activity (umol/min.g): TC:  $1.43 \pm 0.81$ , TA:  $2.11 \pm 1.39$ , C:  $1.71 \pm 0.49$  and A:  $1.58 \pm 0.89$ . **Discussion:** The results suggest that the high intensity resis-

tance training as well as the alloxan administration protocols were not effective in changing oxidative stress biomarkers in the pancreas of rats. Alternative procedures for diabetes induction and exercise training must be employed for the study of this matter. Support: Fapesp (proc. 09/51538-5), Capes. References Radak Z, Chung HY, Goto S. ### HIGH LEVELS OF OXIDATIVE LDL AFTER A MARATHON RACE AND ATHEROGENESIS IN ATHLETES

VAISBERG, M.1, MARANHÃO, R.2, SANTOS, J.M.B.1, DIOGUARDI, G.3, GHORAYEB, N.3, BACHI, A.L.L.1

1 FEDERAL UNIVERSITY OF SÃO PAULO, 2 CARDIOLOGY INSTITUTE OF UNIVERSITY OF SÃO PAULO, 3 DANTE PAZZANESE CARDIOLOGY INSTITUTE

**Introduction:** Recently it has been shown that marathon runners can show a coronary artery calcification (CAC) index similar to sedentary match controls. This unexpected finding can be caused by some factors. Levels of plasmatic oxidized LDL are important due to their participation on atherogenic process and levels of the auto-antibody anti-LDL also are important because they participate in the control of the action of LDL. **Methods:** We studied marathon runners with and without coronary artery calcification, comparing levels of plasmatic ox-LDL and anti-LDL. The group of marathon runners was composed by 28 male runners from São Paulo, with a range of age from (25 to 60) means 41.4 years old. The marathon runners were separated by angiotomography in two groups: with atherosclerosis process (AP, n=5) or without atherosclerosis process (WAP, n=23). We evaluated the level of oxidative LDL cholesterol fraction (oxLDL – U/L) and anti-LDL auto-antibody (U/L) in both groups at rest, immediately and 72 hours after a marathon. **Results:** We observed that the levels of oxLDL ( $99.46 \pm 23.31$ ) and anti-oxLDL ( $471.1 \pm 213.7$ ) in AP group at rest did not differ in relation to WAP group ( $86.55 \pm 19.67$  and  $422.7 \pm 75.92$ , respectively). The results observed immediately after a marathon showed that the levels of oxLDL in AP ( $166.5 \pm 40.53$ ) and WAP ( $146.6 \pm 74.27$ ) groups were significantly higher than basal levels ( $p < 0.01$ ), but didn't show statistical significance when comparing values between these two groups. Although levels of anti-oxLDL in AP ( $372 \pm 83.91$ ) and WAP ( $366.8 \pm 68.77$ ) groups were reduced, they have not show statistically significant differences nor to basal level neither between the groups. The analysis of results obtained 72 hours after a marathon, shows that the levels of oxidative LDL in the NAP ( $93.68 \pm 26.04$ ) group return to basal levels, however the concentration in AP group ( $115.4 \pm 23.70$ ,  $p < 0.05$ ) kept statistically increase in comparison to levels at rest. No statistical difference was observed between groups. The concentration of Anti-oxLDL in AP ( $216.2 \pm 193.8$ ) and WAP ( $294.7 \pm 75.92$ ) groups showed a tendency toward decrease but didn't show any statistically significant difference. **Discussion:** In this research we were able to demonstrate a difference between athletes with or without coronary artery calcification, based on the maintenance of elevated levels of oxLDL after a marathon, a factor that can be implied with the process of atherogenesis.

### OXIDATIVE STRESS STATUS IN FEMALE INTERNATIONAL-LEVEL SPRINTERS DURING TAPERING

SUGIURA, K.1, KAWAMOTO, K.1, YOSHIDA, M.2, AKAMA, T.3

1 FUKUSHIMA UNIVERSITY, 2 NATUREAL, 3 WASEDA UNIVERSITY

**PURPOSE:** Oxidative stress increases during intense exercise and affects the athlete's physical condition. Therefore, it is important to continuously measure oxidative stress and antioxidant ability with respect to physical condition for evaluating the athlete's whole-body fatigue. The purpose of this study was to analyse the physical condition of international-level athletes by continuous measurement of oxidative stress and antioxidant ability. **METHODS:** The study population comprised 8 female international-level sprinters. Their oxidative stress levels and antioxidant ability were measured every week for 2 months before the competition. We collected blood samples from their earlobes before each training session was initiated. The sprinters trained for 3 hours per day for 5 days per week. They had a tapering period for the 10 days before the competition. We measured the total plasma hydroperoxide concentration (derivatives of reactive oxygen metabolites [d-ROMs] test; FREE, Diacron) as a barometer of oxidative stress and the ferric-reducing ability of plasma as a barometer of antioxidant ability (biological antioxidant potential [BAP] test; FREE, Diacron). Furthermore, we calculated the BAP test:d-ROMs test ratio by using the equation described by NAGATA et al (2008) and considered this ratio as the oxidative stress status. **RESULTS:** The total hydroperoxide concentration remained between  $276.3 \pm 21.1$  U.CARR (normal) and  $305.5 \pm 46.9$  U.CARR (slightly higher than normal) from 8 weeks to 1 week before the competition. However, it decreased to  $231.9 \pm 21.4$  U.CARR immediately before the competition because the athletes had a tapering period for 10 days before the competition. The ferric-reducing ability decreased slowly during the 8 weeks before the competition, i.e. from  $2.634 \pm 0.148$  mmol/l to  $2.204 \pm 0.205$  mmol/l; these levels are considered normal ( $> 2.2$  mmol/l). The BAP test:d-ROMs test ratio decreased from  $1.31 \pm 0.32$  to  $0.98 \pm 0.10$  during the first month and increased slowly until it reached  $1.26 \pm 0.10$  (normal level  $> 1.0$ ) immediately before the competition because of tapering. **CONCLUSIONS:** The oxidative stress levels (measured using the d-ROMs test) increased and the BAP test:d-ROMs test ratio decreased during intense training sessions; these values returned to normal levels after tapering. Because the oxidative stress status was controlled, the sprinters' performances improved. Inability to maintain if athletes could not controlled the oxidative stress at normal levels negatively affected the sprinters' performance. These results suggest that continuous measurement of oxidative stress and antioxidant ability is possible for athletes to conditioning.

### THE EFFECTS OF A TRAINING SEASON ON OXIDATIVE STRESS IN YOUNG TRACK AND FIELD ATHLETES

ZALAVRAS, A.1, THEODOROU, A.A.1, NIKOLAIDIS, M.G.2, PASCHALIS, V.1, OIKONOMOU, D.1, SOULAS, D.1, FATOUROS, I.G.3, KOUTEDAKIS, Y.1, JAMURTAS, A.Z.1

1: UTH (GREECE) 2: CERETETH (GREECE) 3: DUTH (GREECE).

**Introduction** Data regarding the exercise-induced oxidative stress and adaptations of the antioxidant defense system in adolescent and child athletes is still scarce (Djordjevic et al. 2011; Kabasakalis et al. 2009). The aim of this study was to compare the effects of a training season on indices of oxidative stress and the antioxidant defense system in young track and field athletes. **Methods** Thirteen young athletes (age:  $14.2 \pm 1.1$ ; weight:  $53.5 \pm 8.8$ ; height:  $165.2 \pm 7.7$ ) and 10 control individuals (age:  $14.8 \pm 1.0$ ; weight:  $65.4 \pm 13.0$ ; height:  $172.9 \pm 9.5$ ) participated in this study. Blood was collected three times during the training season. The first blood drawing was performed prior to the training season (PRE), the second one was performed at mid-training season (MID) when the training load was increased and the third blood drawing was performed at the end of the training season (END). Protein carbonyls (PC), thiobarbituric acid reactive substances (TBARS), uric acid and bilirubin were measured as indices of blood redox status. **Results** The results of the present study did not reveal any significant differences between the groups at any timepoint for none of the redox status indices employed. **Discussion** These results indicate that there are no changes in redox status in young track and field athletes during a training season when the training volume is

significantly increased. References Djordjevic D, Cubrilo D, Macura M, Barudzcic N, Djuric D, Jakovljevic V. (2011). Mol Cell Biochem, 25, (In press). Kabasakalis A, Kalitsis K, Nikolaidis MG, Tsalis G, Kouretas D, Loupos D, Mougios V. (2009). J Sci Med Sport, 12, 691-6.

### REGULAR EXERCISE PRODUCE HIGHER ANTIOXIDANT CAPACITY THAN SEDENTARINESS AFTER 3000-METERS JOGGING AEROBIC EXERCISE

TSENG, W.P., SU, C.M.

NATIONAL CHANGHUA UNIVERSITY OF EDUCATION

**Introduction** High intensity endurance exercise induces oxidative stress in human erythrocytes. The aim of this study was to explore the effect of aerobic exercise in 3000-meters jogging on antioxidant capacity between college students with different exercise habits. **Methods** Twenty male college students were recruited and divided into sedentary group and regular exercise group. After the participants performed aerobic exercise in 3000-meters run, the blood samples were obtained before aerobic exercise and after aerobic exercise immediately, 24 and 48 hours. Biochemical analysis included total glutathione (TGS), superoxide dismutase (SOD) and uric acid (UA). **Results** The result of sedentary group indicated that total glutathione (TGS) concentration was decreased after aerobic exercise immediately; superoxide dismutase (SOD) activity was decreased after aerobic exercise 24 and 48 hours; uric acid (UA) activity was increased after aerobic exercise 24 and 48 hours ( $p < .05$ ). In the regular exercise group indicated that TGS concentration was increased after aerobic exercise 24 hours; SOD activity was increased after aerobic exercise 48 hours; uric acid (UA) activity was decreased after aerobic exercise 48 hours ( $p < .05$ ). Consequently, after the participants performed aerobic exercise in 3000-meters run, the antioxidant capacity of sedentary group could be increased in 48 hours after aerobic exercise. **Discussion** We concluded that not only TGS was increased in 24 hours but also SOD was increased in 48 hours after aerobic exercise in regular exercise group. Therefore, our results suggest that the antioxidant capacity in regular exercise group would be increased by TGS and SOD respectively after 3000-meters jogging of aerobic exercise 24 and 48 hours. Based upon these results, we suggest people should maintain exercise regularly to increase antioxidant capacity. **References** Centin E, Top EC, Sahin G, Ozkaya YG, Aydin H, Toraman F. (2010). #### EFFECT OF CONDITIONING TRAINING COMBINED WITH PLYOMETRIC JUMPS ON PHYSICAL FITNESS IN YOUTHS WITH DOWN SYNDROME

GONZÁLEZ-AGÜERO, A., VICENTE-RODRÍGUEZ, G., OLMEDILLAS, H., GÓMEZ-CABELLO, A., ARA, I., MORENO, L.A., CASAJÚS, J.A.

GENUD (GROWTH, EXERCISE, NUTRITION AND DEVELOPMENT) RESEARCH GROUP, UNIVERSITY OF ZARAGOZA, ZARAGOZA, SPAIN.

**Introduction:** Children and adolescents with Down syndrome (DS) have shown lower levels of physical fitness compared with their peers without DS(1). Physical fitness, especially cardiovascular fitness, is an important marker of health during childhood and adolescence. It is well known that training programs improve physical fitness in healthy children and adolescents; however, it is not totally clear what happens in youths with DS(2). Therefore, the aim of this study was to determine whether youths with DS could improve their cardiovascular fitness after 21 weeks of conditioning and plyometric exercise training. **Material and methods:** 28 participants with DS (17 males) aged from 10 to 19 years and 30 sex- and age-matched controls without disabilities joined the study. Participants with DS were divided into two groups, DS-exercise and DS-control. Time of exercise and peak cardiorespiratory values ( $VO_{2peak}$ ,  $HR_{peak}$ ,  $RER_{peak}$ ,  $VE_{peak}$ ) were measured by a maximal effort treadmill test at baseline and after the training program. The conditioning training consisted of 21 weeks, 2 sessions per week of circuits with different kind of jumps, press-ups and exercises with elastic fitness bands and adapted medicine balls, for approximately 15 to 25 minutes/day. Mann-Whitney U and Wilcoxon-Cox tests were used to evaluate the differences between groups, and between evaluations within the same group. **Results:** DS-exercise participants increased their  $VO_{2peak}$ ,  $RER_{peak}$ , time of exercise,  $HR_{peak}$  and  $VE_{peak}$  comparing baseline with post-training ( $p < .05$ ); these differences were not observed in the DS-control exercise. No differences were observed between DS-groups before training, DS-exercise group showed higher  $VO_{2peak}$ ,  $RER_{peak}$  and  $HR_{peak}$  than the DS-control group post-training ( $p < .05$ ). The  $VO_{2peak}$  of DS-exercise girls, after training, did not differ from the  $VO_{2peak}$  of control girls, neither the time of exercise and  $RER_{peak}$  of DS-exercise boys compared with control boys. **Conclusion:** Overall, 21 weeks of conditioning training combined with jumps is an effective method to improve cardiovascular fitness of youths with DS; efforts should be made in order to promote physical activities in youths with DS. **Acknowledge:** This study was supported by Gobierno de Aragón (Project 17/2007) **References:** 1. #### THE TEACHING OF MARTIAL ARTS TO PEOPLE WITH DISABILITIES

GOMES, M., MORATO, M., TERRISSE, A., ALMEIDA, J.

FACULTY OF EDUCATION PHYSIQUE-STATE UNIVERSITY OF CAMPINAS

The teaching of martial arts to people with disabilities Mariana S.P.Gomes<sup>1,2</sup>, Márcio P.Morato<sup>1</sup>, André Terrisse<sup>2</sup>, José J.G.Almeida<sup>1</sup>. Faculty of Physical Education, University of Campinas, Brazil<sup>1</sup> Institute Universitaire de Formation de Maîtres -Université de Toulouse II, France<sup>2</sup> **Introduction** The teaching of martial arts usually emphasizes the perfect technique execution, instead of the logic of combat and its reasons of application (Terrisse, 1991). We suppose that this can lead to the restriction of possibilities martial arts can offer, not contemplating some of the sports pedagogy personages, such as people with disabilities (Winnick, 2005). In this sense, this study seeks to analyze the strategies of teaching martial arts for this group of people. **Methods** We used the qualitative research to comprehend what four physical education teachers and masters in different modalities (Judo, Jiu Jitsu, Taekwondo, Karate and Fencing) think and do when they have students with any disabilities. We used semi-structured interviews that were analyzed by the enunciation technique, one of the

content analysis techniques (Bardin, 1998). Results and Discussion The results suggest that having a student with disability demands adaptation procedures from the teachers, resulting in new teaching methods. Some interviewed teachers related the adaptation of the regular methods according to the type of disabilities. There is a change of the focus on the exclusive technique elements of the combat (Villamón, Molina, 1999), to the tactic and strategy emphasis. In these cases, when they tried to explore the dynamic of the combats, the students were able to solve problems and reach the objectives of the activities, disregarding the perfection of their techniques. However, when the activity demanded the perfect technical gesture, some teachers related that the teaching process was not possible because the students could not execute the proper techniques. Conclusion The results showed that when working with disabled students it is important to privilege the tactical aspects, instead of the single technique, in order to transmit the logic of combat and possibilities to solve the problems of the proposed activities. This method enables the martial arts teaching to anyone, because the focus is in the student's potentiality, in what he is able to do, not in his disability. In this context, they will be stimulated to create different ways to use the traditional techniques as well as develop new ones. References Bardin, L. (1998). *L'analyse de contenu*. Paris. PUF. ## REGULAR LEVEL AND DOWNHILL TREADMILL WALKING AT SELF-SELECTED SPEED IMPROVES FUNCTIONAL PERFORMANCE OF OLDER ADULTS

GAULT, M., CLEMENTS, R.E., WILLEMS, M.E.T.

UNIVERSITY CAMPUS SUFFOLK

REGULAR LEVEL AND DOWNHILL TREADMILL WALKING AT SELF-SELECTED SPEED IMPROVES FUNCTIONAL PERFORMANCE IN OLDER ADULTS Gault, ML1, Clements, RE.2, Willems, MET.2 1: University Campus Suffolk (Ipswich, UK), 2: University of Chichester (Chichester, UK) Introduction Older adults experience reductions in muscle strength, functional capacity and quality of life (Doherty, 2003). Exercise programs may preserve muscle strength and physical functioning (Trappe et al., 2002). We examined functional performance and dynamic strength following a program of regular level and downhill treadmill walking (i.e. concentric or eccentric endurance exercise) at self-selected walking speeds. Methods 18 healthy elderly adults ( $67 \pm 5$  yrs,  $170 \pm 9$  cm,  $77.2 \pm 13.9$  kg) volunteered. Participants completed 12-weeks of level (LW: 0% gradient (n=8)) or downhill (DW: -10% gradient (n=10)) treadmill walking (30-mins, 3x week) at a self-selected walking speed (SSWS, re-adjusted every 4-wk). Maximal walking speed (MWS), 5-repetition sit-to-stand (5-RSTS), timed up-and-go (TUG), peak torque of knee extension (concentric: 600/s and 1800/s, eccentric: 1800/s) and angle of peak torque were measured at baseline (B) and following 12-weeks (P) of LW and DW. A two way repeated measures ANOVA with post-hoc pre-planned t-tests were used for data analysis ( $P < 0.05$ ). Results SSWS was similar for both groups and increased from  $1.18 \pm 0.11$  to  $1.53 \pm 0.09$  m·s<sup>-1</sup> (LW) and  $1.26 \pm 0.16$  to  $1.61 \pm 0.12$  m·s<sup>-1</sup> (DW) ( $P < 0.01$ ). Improvements in MWS, 5-RSTS and TUG were similar ( $P < 0.01$ ). MWS (baseline LW:  $2.39 \pm 0.38$  m·s<sup>-1</sup>, DW:  $2.40 \pm 0.33$ ) improved by 22 and 23%. 5-RSTS (baseline LW:  $8.50 \pm 1.19$ s, DW:  $8.54 \pm 1.52$ s) improved by 32 and 34%. TUG (baseline LW:  $5.58 \pm 0.51$ s, DW:  $5.46 \pm 0.89$ s) improved by 22%. Peak torque values did not change. However, in both groups, the angle at which concentric peak torque ( $180^\circ$ ·s<sup>-1</sup>) occurred was decreased after 12-weeks (LW:  $37 \pm 16^\circ$  to  $26 \pm 14^\circ$ ; DW:  $42 \pm 18^\circ$  to  $37 \pm 16^\circ$ ,  $P < 0.05$ ). Discussion Regular level and downhill treadmill walking at a self-selected walking speed resulted in substantial improvements in functional performance. However, changes in functional performance could not be explained by changes in concentric and eccentric strength of knee extensor muscles. A change in concentric peak torque angle may indicate a shift in the knee angle-torque relationship of knee extensor muscles (Narici et al., 2003). This may be explained by an increase in muscle fascicle length due to addition of sarcomeres in series (Goldspink, 1998) as a result of regular level and downhill treadmill walking in older adults. Regular treadmill walking at a self-selected speed may serve as a novel exercise intervention to examine adaptations in elderly people. References Doherty TJ. (2003). *J Appl Physiol*, 95, 1717-1727. ## PREDICTORS OF FEMORAL NECK BONE MINERAL DENSITY: THE ROLE OF MODIFIABLE AND NON-MODIFIABLE FACTORS

MARQUES, E.A.1, MOREIRA, P.1,2, WANDERLEY, F.1, PIZARRO, A.1, SOUSA, F.3, MOTA, J.1, CARVALHO, J.1

1: CIAFEL-FADEUP (PORTO, PORTUGAL), 2: FCNAUP (PORTO, PORTUGAL), 3: CIFI2D (PORTO, PORTUGAL)

Introduction Areal bone mineral density (BMD) is a surrogate measure of the breaking strength of bone and is a sensitive predictor for fractures (Cummings, Bates et al. 2002). Taking into account that BMD is a complex trait, influenced by genetic and environmental factors (Kung and Huang 2007), the insight into both parts requires the study of several factors, frequently categorized as modifiable and non-modifiable. Therefore, the present cross-sectional study aimed to examine the relationships between BMD and physical activity, muscle strength, genetic, demographic and dietary factors in older adults. Methods One hundred twenty seven healthy Caucasian older adults (mean age 69 years) free of medications known to affect bone were enrolled. Femoral neck BMD and body composition (lean and fat tissue) were measured by dual X-ray absorptiometry. Dietary intake was assessed by 4-day dietary record. Performance measures included the knee extension strength measured on an isokinetic dynamometer. Physical activity was assessed using accelerometers. Sociodemographic information, lifestyle behaviors and clinical status were also examined by questionnaire. Lactose persistence mutations G/C -14010, T/G -13915, C/T -13910 and C/G -13907 were genotyped by direct sequencing. Net endogenous acid production was also calculated. Results Stepwise multiple linear regression analysis showed that male gender and higher BMI were significant positive predictors of femoral neck BMD, while age was a significant negative predictor (50.3% of variance), even after adjustment for confounders. Discussion The present work confirmed that sex is a powerful predictor of BMD in older adults, pointing towards the greater bone mass associated with male gender. Expectedly, our data revealed that age is a significant predictor of BMD in older adults, which was previously demonstrated by others (Bass, Ford et al. 2006). Our observation that BMI was a significant positive predictor of femoral neck BMD is in agreement with previous studies (Tang, Sheu et al. 2007). In conclusion, our data highlight that older adults, particularly female with low BMI are important target population for interventions to prevent osteoporosis. **EFFECTIVENESS OF A 6-MONTH WATER-BASED EXERCISE IN PREVENTING PHYSICAL DECLINE IN ELDERLY SUBJECTS.**

BERGAMIN, M., TOLOMIO, S., ERMOLAO, A., ZACCARIA, M.

UNIVERSITY OF PADOVA

The development and progression of sarcopenia is a complex and multi-factorial process. A growing body of evidence indicates that physical activity in elderly can slow the loss of skeletal muscle and function. Among exercise modalities, water-based protocols are suggested for subjects in whom a lower joint stress is recommended, however, limited data are available about their actual effects in maintaining muscle mass and physical fitness. **PURPOSE:** To determine the effect in body composition, strength and flexibility of a physical activity program performed in thermal water respect to a similar land-based protocol. **METHODS:** 40 subjects (N=20 Male, N=20 Female) were recruited (age = 71.7 yrs, BMI = 26.2 kg/m<sup>2</sup>), and randomly allocated to two groups: Aquatic Group (AG) and Land Group (LG). During the 6 months, subjects followed a twice-a-week exercise intervention. Exercise intensity was monitored using Borg's Scale and heart rate. Functional evaluation was performed before and after the exercise protocols. Body composition was assessed by bioimpedance analysis, strength by handgrip dynamometry, as well as isotonic knee extension. Physical performance was also assessed using the Senior Fitness Test. Statistical analysis was made using ANOVA for repeated measures. Because of healthy reasons or lack of interest in participation, 6 subjects dropped out from the study (2 in AG vs 4 in LG). **RESULTS:** AG showed a significant reduction in body weight (69.7±13.3 to 68.8±13.6 kg,  $p<0.05$ ) and fat mass (21.9±5.8 to 20.9±5.6 kg,  $p<0.05$ ), while LG did not. AG and LG improved both in 8-foot up & go (5.6±1.2 to 4.9±0.7,  $p<0.05$  and 6.1±2.1 to 5.3±2.1 seconds,  $p<0.05$ ) and modified sit & reach tests (AG 2.8±6.7 to 12.8±6.7 cm in right leg,  $p<0.05$ ; AG 3.5±8.0 to 13.33±7 cm left leg,  $p<0.05$ ; LG 5.0±12.6 to 13.4±11.5 cm in right leg,  $p<0.05$ ; LG 5.6±12.1 to 13.7±11.7 cm in left leg,  $p<0.05$ ). Handgrip strength proved a significant increase only in LG (18.7±8.4 to 23.5±9.1 kg,  $p<0.05$ ). The other tests demonstrated a similar, not significant, positive trend. **CONCLUSIONS:** Both land and water-based activities seem beneficial in improving dynamic balance and flexibility. Strength values appear maintained. Further analysis will allow evaluation of muscle mass by peripheral quantitative computed tomography and the comparison with a control group.

**EFFECTS OF HIGH-RESISTANCE CIRCUIT VS. TRADITIONAL STRENGTH TRAINING ON BODY COMPOSITION AND STRENGTH IN OLDER WOMEN**

ROMERO-ARENAS, S.1, MARTÍNEZ, M.2, PÉREZ-GÓMEZ, J.3, BLAZEVIČ, A.J.4, LUQUE, A.J.1, ROMÁN, J.1, MORILLAS, J.M.1, ALCARAZ, P.E.1

1UCAM (MURCIA, SPAIN), 2HOSPITAL UNIVERSITARIO SANTA MARÍA DEL ROSELL (CARTAGENA, SPAIN), 3UEX (CÁCERES, SPAIN), 4ECU (PERTH, WESTERN AUSTRALIA, AUSTRALIA).

**Introduction:** Traditional strength training (TS) has been used in several populations, including children, young adults, and older adults (Brentano et al., 2008). However, there is no information about high-resistance circuit training (HRC) (Alcaraz et al., 2008) in healthy older women. The purpose of the present study was to compare the effects of 12 weeks of HRC vs. TS on upper and lower limb isokinetic strength, lean mass, fat mass and bone mineral density (BMD). **Methods:** Thirty-seven women (55-75 years old) were randomly assigned to a TS (n = 15, 6RM, 1-3 sets) or to a HRC (n = 15, 6RM, 1-3 sets), and a control group (CG, n = 7, no exercise). Training consisted of weight lifting 2 times a week during 12 weeks. Prior to and at the end of the training program, maximum isokinetic strength (90°•s<sup>-1</sup> and 270°•s<sup>-1</sup>) and body composition (DXA) were determined. Main and interaction effects resulting from the intervention were analyzed using single or multivariate analyses of variance (ANOVA) with repeated measures ( $p \leq 0.05$ ). **Results:** After training, total fat free mass was increased in the HRC group (4.5%) and total fat mass was decreased in the HRC group (3.3%). There were no changes in the BMD for TS and HRC. A significant increase of isokinetic strength was observed in both experimental groups for the angular speeds of 90°•s<sup>-1</sup> and 270°•s<sup>-1</sup> in upper and lower limbs, being established statistically significant differences among TS and CG, and among HRC and CG. In the CG, there were no changes in the variables analyzed. **Conclusion:** The results seem to indicate that there is an improvement in the upper and lower limbs strength with both training methods. However, only a significant decrease in fat mass was found in HRC group. There were no changes in the BMD for TS and HRC, probably a long-term training should be applied for improving bone adaptations. **References:** Alcaraz, P.E., Sánchez-Lorente, J., & Blazevič, A.J. **OSTEOPOROSIS AND LIFESTYLE IN ELDERLY PEOPLE**

GOMEZ CABELLO, A., GONZÁLEZ-AGÜERO, A., CASAJÚS, J.A., ARA, I., VICENTE-RODRÍGUEZ, G.

GENUD RESEARCH GROUP. UNIVERSITY OF ZARAGOZA

**Osteoporosis and lifestyle in elderly people** Gómez-Cabello A1, González-Agüero A1, Casajús JA1, Ara I1,2, Vicente-Rodríguez G1 1 GENUD Research Group, University of Zaragoza, Zaragoza, Spain 2 University of Castilla-La Mancha, Toledo, Spain **Introduction:** osteoporosis constitutes a growing problem worldwide that has a deep impact on quality of life and mortality (1). In younger populations, physical activity has been associated with increased bone mass whereas a sedentary lifestyle has been linked to a reduced bone mass (2). This study aimed to test whether the self-reported lifestyle (active/sedentary behaviours) could have a relationship with the risk of osteoporosis among elderly. **Material and methods:** 218 subjects (63 men and 155 women) aged 73.04±5.8 were evaluated in Aragón (Spain) within the framework of the elderly EXERNET multi-centre study. Bone mineral density was assessed at lumbar spine and hip sites by dual-energy X-ray absorptiometry. Sample was classified into three different groups according WHO guidelines (3) taking into account T-Score values at lumbar spine and hip sites. Self-reported physical activity, hours of walking and hours spent sitting per day were recorded by a questionnaire. Logistic regression was applied to study the association of the self-reported lifestyle with the risk of osteoporosis after controlling for age, height, lean and fat masses as confounders. **Results:** those women who spent sitting less than 4 hours per day showed 81.6% lower risk of suffering osteoporosis compared with those spending more time sitting (95% CI [0.045-0.749]). No association between sedentary lifestyle and risk of osteoporosis in men was found. Neither hours walking per day nor regular physical activity were independently associated with lower risk of osteoporosis in men or in women. **Discussion:** the absence of objective measures of active behaviours and the lack of information regarding the intensity of the activity could mask a positive association between active lifestyle and risk of osteoporosis. **Conclusion:** a sedentary lifestyle has a great impact on bone health among elderly, and therefore, reducing the hours sitting per day among seniors could reduce the risk of suffering osteoporosis, especially in elderly women. ## **METABOLIC RESPONSE TO HYPERGLYCAEMIA DURING EXERCISE IN ELDERLY AND YOUNG MALES**

MACLAREN, D.

LIVERPOOL JOHN MOORES UNIVERSITY

Metabolic response to hyperglycaemia during exercise in elderly and young males JM Malone<sup>1</sup>, SC Waldron<sup>2</sup>, IT Campbell<sup>2</sup>, A Hulton<sup>1</sup>, D Doran<sup>1</sup>, DPM MacLaren<sup>1</sup> <sup>1</sup> Department of Sport and Exercise Science, Liverpool John Moores University, Tom Reilly Building, Liverpool, L3 5AF and <sup>2</sup> Department of Anaesthesia, University Hospital of South Manchester, Manchester, M23 9LT Ageing is associated with an increased incidence of insulin resistance and body composition changes. We evaluated the physiological responses to maintained hyperglycaemia during exercise between young and elderly males. Eight endurance trained elderly (69.1 ± 5.2 y) and young (22.4 ± 2.9 y) males were studied during 40-min cycling exercise (60%) under both hyperglycaemic (10mM glucose) and control (0.9% saline) infusion conditions. Baseline anthropometric and physiological data revealed that participants were matched for body mass (76.3 ± 10 v 78.6 ± 4.3 kg) and % body fat (20.8 ± 4.3 v 18.9 ± 3.9%) whereas the elderly had significantly lower VO<sub>2</sub>max (41.1 ± 12.2 v 55.8 ± 5.1 ml.kg<sup>-1</sup>.min<sup>-1</sup>) and HOMA-2%B (63.6 ± 22.4 v 125.3 ± 78.2; P < 0.05). Venous blood samples were collected at baseline, post prime infusion, and at 20 and 40-min during exercise for insulin, glucose, NEFA, glycerol, lactate and 3-hydroxybutyrate. Carbohydrate and fat oxidation rates were determined using indirect calorimetry, and the hyperglycaemic clamp enabled calculation of glucose utilisation. The young displayed higher rates of carbohydrate oxidation (2.19 ± 0.51 g.min<sup>-1</sup>) compared to the elderly (1.51 ± 0.58 g.min<sup>-1</sup>; P < 0.01) with no differences in fat oxidation evident. Higher glucose utilisation rates were also observed in the young compared to the elderly at both 0 – 20 minutes (85.76 ± 23.95 and 56.67 ± 15.09 μM.kg<sup>-1</sup>.min<sup>-1</sup>, respectively) and at 20 – 40 minutes (104.87 ± 17.79 and 57.60 ± 29.30 μM.kg<sup>-1</sup>.min<sup>-1</sup>, respectively) Despite a blunted insulin response in the elderly (p = 0.01), no differences were observed for NEFA, glycerol, lactate and 3-OHB between groups. These data suggest that elderly males have a reduced ability to oxidise carbohydrate and dispose of glucose during exercise under conditions of maintained hyperglycaemia. In part this may be due to diminished beta-cell function resulting in lower levels of insulin despite no differences in insulin sensitivity.

## **EFFECT OF EXERCISE TRAINING TO HEALTH RELATED QUALITY-OF-LIFE IN MIDDLE-AGE AND OLDER ADULTS**

TAKAHASHI, S., SUZUKI, K.

TOHOKU GAKUIN UNIVERSITY

**PURPOSE** To compare the direct effects of exercise training to the health related Quality-of-life (HRQOL) and the indirect effects of exercise training to HRQOL through the changes of physical fitness and physical activity. **METHODS** Fifteen females (54+/-3.6 years) and five males (66+/-7.6 years) participated in a 12-week exercise-training program. The program consisted of 12 training sessions; contents of the session were 20-min of warm-up, 20-min of walking, 40-min of resistance training with an elastic band and a balance ball, and 10-min cool-down. The frequency of training was once a week. Before and after the program, HRQOL, physical fitness, and physical activity of the participants were measured. The HRQOL was assessed using 4 domains of the WHOQOL-BREF (Physical, Psychological, Social, and Environmental QOL). Physical fitness was measured by grip strength, sit-ups, sit-and-reach, single-leg balance with eyes open, 10-m hurdle walk, and 6-min walk. Physical activity (METs•h) was measured by an accelerometer for before and last 1 week in the training program. The direct effects of training to HRQOL were estimated by the main effect of the two-way ANOVA with repeated measurements (factors were gender 2 levels and training 2 levels). The indirect effects of training to HRQOL were correlation coefficients between the changes of HRQOL and the changes of physical fitness components and physical activity. **RESULTS** The results of ANOVA model showed significant improvements of Physical (F (1, 18) = 6.8, p = 0.018), Psychological (F (1, 18) = 14.7, p = 0.001), Social (F (1, 18) = 9.2, p = 0.007), and Environmental QOL (F (1, 18) = 15.6, p = 0.001). In physical fitness components, sit-and-reach (F (1, 18) = 8.8, p = 0.008) and 6-min walk (F (1, 18) = 27.4, p < 0.001). Physical activity also significantly increased F (1, 18) = 23.8, p < 0.001). While the direct effects of training to HRQOL was significant, there were no significant correlation coefficients between the changes of HRQOL and the changes of physical fitness and physical activity (absolute value of r < 0.36, p > 0.12). **CONCLUSIONS** These results showed that exercise training directly effected improvement of the HRQOL in middle and older Japanese adults.

## **LONG-TERM EFFECTS OF TRAINING ON MUSCLE STRENGTH IN OLDER ADULTS**

KVAMME, N.H., SOLBERG, P.A., HALLÉN, J., RAASTAD, T.

NORWEGIAN SCHOOL OF SPORT SCIENCES

**Introduction** Several studies have shown beneficial training effects on health and physical function in older adults. To further investigate the effects of these studies a long term follow up is needed, to see whether the effects of the intervention persist over time. Previous studies have shown that muscle strength was preserved 6 months after a traditional heavy strength training program over 6 months (Beyer et al., 2007), but not after 12 weeks of functional training (Giné-Garriga et al. 2010). The aim of this study was to evaluate the long term effect of different training programs on muscle strength in elderly. **Methods** This study was a 12 months follow-up of subjects participating in a 13-week training study. The participants (70-92 years) had been randomly divided into a strength training group (STG), a functional strength training group (FTG) and an endurance training group (ETG). Muscle strength was measured as 1RM in four different exercises (chest press, seated row, shoulder press and knee extension) before intervention (T1), after the intervention (T2), and 12 months later (T3). All data were analyzed with linear mixed modeling, and results are given in effect sizes with 95% confidence limit. An effect of 0.2 of the baseline SD is regarded small, 0.6 moderate and 1.2 large (Hopkins et al., 2009). **Results** Out of the 85 elderly who completed the training intervention, 62 completed the T3 data collection. The increases observed during the intervention period were largest for STG, followed by FTG. At T3, strength was slightly reversed, and more in the two strength groups compared to ETG. For STG, a reduction was observed in chest press (ES=-0.25; ±0.17), shoulder press (ES=-0.47; ±0.19) and knee extension (ES=-0.97; ±0.29), while decreases were observed in shoulder press (ES=-0.30; ±0.21) and knee extension (ES=-0.90; ±0.35) for FTG. The only substantial decrease in ETG was in knee extension (ES=-0.44; ±0.30). From T1 to T3, small positive effects were observed in chest press for STG (ES=0.31; ±0.13) and FTG (ES=0.25; ±0.17), in seated row for STG (ES=0.34; ±0.18), and in knee extension for STG (ES=0.36; ±0.34), FTG (ES=0.30; ±0.35) and ETG

(ES=0.47;  $\pm 0.27$ ). The increase observed in STG was substantially different from ETG (ES=0.20;  $\pm 0.25$ ) for seated row. Discussion The most important finding of this study was that 12 months after the initial intervention period, strength was generally higher than before the intervention start. The two strength training groups tended to decrease more than ETG from post intervention to 12 months. This was most likely due to larger gains in strength during the intervention, and thus it may have been more demanding to sustain the increased strength during the follow up period. ### EFFECTS OF NON-PHARMACOLOGICAL INTERVENTIONS ON HEALTH RELEVANT PARAMETERS IN CONGESTIVE HEART FAILURE PATIENTS

WRIGHT, P.1, DROESE, K.2, VÖLKER, K.3, SCHULZ, H.1

1: CHEMNITZ UNIVERSITY OF TECHNOLOGY; 2: PRACTICE FOR CARDIOLOGY AND SPORTS MEDICINE (DORTMUND); 3: WESTPHALIAN WILHELMUS UNIVERSITY (MUNSTER)

Objectives: The objective of this study was to examine the physiological effects that various exercise training methods have on CHF patients. Methods: 100 patients were randomised and divided in to an Endurance group (ETG, n=25), High intensity strength training group (STG, n=25), Circuit training group (CTG, n=25) and a Dietary comparison group referred to as non-training group (NTG, n=25). The interventions took place over a period of six months with three testing points. 78 patients (ETG: n=21; STG: n=20; CTG: n=20; NTG: n=17) completed the study. Results: The EF increased significantly in all training groups at all test points (ETG: pre  $31 \pm 6\%$  post  $46 \pm 8\%$ ; CTG: pre  $29\% \pm 7\%$  post  $45\% \pm 11\%$ ; STG: pre  $30\% \pm 7\%$  post  $45\% \pm 7\%$ ), but no significant change in the NTG was found. All groups showed a significant improvement in the NYHA classification (by one class). The NT-pro-BNP showed a significant decrease from  $1495 \pm 1555$  pg ml<sup>-1</sup> to  $934 \pm 702$  in the ETG (post vs. pre,  $p < 0.01$ ) and the NTG of  $1557 \pm 907$  to  $1105$  pg ml<sup>-1</sup> (interim vs. pre,  $p < 0.05$ ). Finally the peak VO<sub>2</sub> showed no significant changes in the NTG, but again significant changes in all the training groups. No training-related adverse effects were reported in any intervention group. Conclusion: Supervised outpatient exercise training is safe and beneficial in CHF patients with NYHA class II and III. All exercise interventions have a positive effect on cardiovascular and exercise specific parameters, but there is no significant difference between the various exercise interventions. Looking at the changes expressed in percentage the high intensity strength training group produced the greatest effects. This should be further examined.

### THE EXAMINATION OF THE RELATION BETWEEN THE BACK PAIN AND PHYSICAL STRUCTURE, AND SPORT HABITS ON PEOPLE WHO HAVE SOME BACK PAIN PROBLEMS

ODABAS, I., BULGAN, C., TURAN, T., AKCAL, M.A.

HALIC UNIVERSITY, SCHOOL OF PHYSICAL EDUCATION AND SPORT

Introduction The painful deformity of the musculoskeletal system is cause of work-related disability. So the purpose of this study was to examine of the relationship between physical structure and back pain. The study was designed for people who have some compliments about back pain problems. It was evaluated if there were some correlation between sport and other habits, diseases and risk factors and back pains. Methods In total, 176 people participated to this study. 89 of them (age  $34.72 \pm 5.33$ , height  $171.97 \pm 9.1$ , weight  $75 \pm 15.5$ ) were chosen as a control group and 87 of them (age  $32.9 \pm 7.9$ , height  $171.9 \pm 9$ , weight  $6 \pm 15.5$ ) were chosen who had back pain problems. The study group was chosen from a private sport and health centre members who have been there for 5 years. For anthropometric measurements, Anthropometric Standardization Manual was taken as reference. After all subjects' risk factors searched, physical parameters were measured and BMI, waist hip ratio, fat percent, LBW body surface area were calculated. Risk factors like diseases, life style and sports habits were asked. For statistical analysis, Par Q test was applied. All data was analyzed by SPSS statistical software. Results As a result of this study, 58% of the participants who had back pains did some exercises regularly in the past; 23 % of them did not do any exercises and 6% of them had a licence in some sports branches. There were no any significant correlation between sum of trunk skinfold and sum of extremity skinfold, BMI, BSA, waist hip ratio and body fat. Also there were no correlation between waist hip ratio, sum of trunk and BMI. Discussion According to the literature, in Leboeuf-Yde and Charlotte DC's review, 32% different studies reported a statistically significant positive weak association between body weight and back pain, also Anderson et al found the prevalence of significant knee, hip, and back pain increases with increased levels of BMI in their study. After all, in present study, there was no any relation between back pain and physical structure especially in some fat parameters. Because of sport habits and histories of the participants might be the reason of this unallied. References 1. Mirtz TA, Greene L. Is obesity a risk factor for low back pain? An example of using the evidence to answer a clinical question. Chiropr Osteopat. 2005 Apr 11;13(1):2. 2. Rodacki AL, Fowler NE, Provensi CL, Rodacki Cde L, Dezan VH. Body mass as a factor in stature change. Clinical Biomechanics. 2005 Oct;20(8):799-805.

### RELATION BETWEEN LOW BACK PAIN AND PHYSICAL ACTIVITY AT ADMINISTRATIVE AND FACTORY WORKERS

SILVA, I.

FADEUP

Introduction: Low back pain (LBP) is the leading cause of disability in adults and the third leading cause of disability after that age. Several studies have studied the relation between LBP and Physical Activity (PA), suggesting that an increase in PA decreased LBP. However, some controversy exists because the PA related to repetitive movements in work context can contribute significantly to the increase in LBP. The aim of this research was to study the relation between PA and LBP. Methodology: It was studied a sample of  $n = 175$  individuals in the employment context. PA was assessed by the International Physical Activity Questionnaire and pain in the lumbar area using the Standardized Nordic Musculoskeletal Questionnaire. Results: There are no statistically significant differences ( $p > 0.05$ ) among subjects with pain and without pain with regard to the average time of daily moderate or vigorous PA. It was found that subjects without LBP, spent significantly ( $p < 0.05$ ) more time sitting than in pain. Discussion: The absence of statistically significant differences between groups of individuals with pain and without pain may be due to the fact that assessments of this variable were done by questionnaire and did not differentiate monitored PA and labour PA. Considering that this sample comes from a workplace in serial production and its administrative, we believe that the significant differences in time between the groups in pain and without pain, is related to the fact that the administrative workers (who are most of the day sitting) do not lift loads, while factory workers (who spend their workday standing) have a large part of their work activities lifting loads. It is thus evident the importance of planning monitored PA programs mainly for workers who lift loads. It was suggested the importance of evaluating PA by methodologies that distinguish between monitored PA and labour PA and are controlled by professionals. References: • Burton AK et al. (2005). #### ANALYSIS OF DUATHLON AND TRIATHLON COMPETITIONS IN YOUNG ATHLETES

COMOTTO, S., CAPRANICA, L., PIACENTINI, M.F.

UNIVERSITY OF ROME

Analysis of Duathlon and Triathlon competitions in young athletes Comotto S, Capranica L, Piacentini M.F. DiSMUS University "Foro Italico", Rome, Italy Introduction The aim of the present study was to investigate the pacing strategy (PS) and the rating of perceived exertion (RPE) during triathlon (TR) and duathlon (D) competitions in 13-year old athletes, which include swimming (S), cycling (C) and running (R) and R, C, R phases, respectively. For both races it has been hypothesized a positive PS with higher RPE scores after the last phase of the competition with respect to previous ones, and a correlation between PS and RPE changes during the race. Methods Four (M=2; F=2) 13-year old athletes participating in both D (R:800m, C:4000m, R:400m) and TR (S:150m, C:4000m, R:800m) Italian championships, took part in the present study. A wearable GPS (SPY Pro X, GPS Sport System, 15hrz) was used to record individual velocities and distance covered. To evaluate PS, 25m, 100m, and 500m mean distance was considered for S, R and C, respectively. RPE scale (Borg, 1998) was administered before, during the 2 transitions (T1 and T2), at the end of the race (E), and at 30-min of recovery (REC). A student paired T-test ( $p < 0.05$ ) was used to verify differences in PS. A 2 (TR and D)  $\times$  4 (T1, T2, E, and REC) ANOVA for repeated measures was applied ( $p < 0.05$ ) to RPE values. Pearson's correlation was applied to RPE and PS. Results For both races, PS resulted positive (TR:-51%; D:-47%), negative (TR:+18%; D:+20%) and even, for the three phases of the race. For RPE, differences ( $p < 0.05$ ) emerged during TR, with higher E values ( $8.3 \pm 1.5$ ) with respect to T1 ( $5.5 \pm 1.3$ ) and T2 ( $7.0 \pm 1.4$ ), whereas similar values were recorded during D (T1: $7.3 \pm 0.9$ ; T2: $7.5 \pm 0.6$ ; E: $7.8 \pm 1.0$ ). PS and RPE showed a significant ( $p < 0.05$ ) correlation only for the first ( $r = 0.98$ ) and last ( $r = 0.97$ ) R phases of D. Discussion To our knowledge, this is the first study to evaluate the PS and RPE during competition in very young athletes. Independently from competition, a positive PS what observed, in line with what reported for elite athletes (Le Meur et al., 2009). In particular, children started with fast velocities and decreased the pace during the race, probably because it is crucial to be included the first group after T1 (Comotto et al., 2011; Vleck et al., 2006). During TR, the highest RPE observed at the end of the competition could due to the effect of the first S phase, which is critical for determining the final ranking (Vleck et al., 2008). However, further research is needed to verify tactical parameters influencing PS. #### PROFILING YOUNG BASKETBALL PLAYERS - THE CONTRIBUTION OF ANTHROPOMETRIC AND TECHNICAL CHARACTERISTICS

TROMP, E.J.Y.1, PANSTERS, L.1, ELFERINK-GEMSER, M.T.1,2, VISSCHER, C.1,2

1: UMCG, RUG (GRONINGEN, THE NETHERLANDS); 2: HAN UNIVERSITY OF APPLIED SCIENCES (NIMEGEN, THE NETHERLANDS)

Introduction Basketball players need to perform according to the demands of their playing position, which require different characteristics. Anthropometric, physiological and technical characteristics have been found to differ between athletes as a function of playing position (Delaxtrat & Cohen, 2009; Hoare, 2000). Identifying these characteristics could help to profile players at an early age, and to provide insights into benefits of position-specific training. Therefore, we examined whether anthropometric, physiological and technical characteristics could discriminate between guards, centers and forwards, and consequently could be useful for profiling basketball players. Methods 60 Talent-identified basketball players aged 13-19 yrs (16 guards, 32 forwards, 12 centers) from the Dutch Premier League were assessed for anthropometric, technical and physiological characteristics. A test battery consisting of basketball-specific field tests was applied. Test scores were compared across playing position. Players from the three positions were similar in age, cumulative years of basketball, cumulative hours of practice per week, and number of games per week ( $p < 0.05$ ). Results One-way ANOVA and Kruskal-Wallis tests revealed differences across playing positions on anthropometric and technical but not on physiological characteristics ( $p < 0.05$ ). Independent t-tests and Mann-Whitney tests revealed centers scoring highest on the anthropometrics height, sitting height, reach height, wingspan, and weight followed by forwards and guards ( $p < 0.05$ ). On the technical characteristics slalom dribble, time difference between slalom dribble and slalom sprint, as well as on star dribble guards performed best followed by forwards. Centers were slower in dribbling and worse in ball handling ( $p < 0.05$ ). Moderate to large effect sizes were found ( $r = .44-.82$ ). Discriminant function analysis revealed that 'height' and 'star dribbling' classified 76% of talented players correctly. Discussion Anthropometric, in particular height, and technical characteristics, in particular dribbling and ball handling, differ between talent-identified basketball players according to playing position. Although selection procedures in youth basketball should be focused on multi-dimensional characteristics, profiling anthropometric and technical characteristics can contribute significantly to positioning basketball players at an early age. A next step is to investigate whether young players benefit from position-specific training. References Hoare DG (2000). J Sci Med Sport, 3, 391-405 Delextat A, Cohen D (2009). #### COMPARISON OF PHYSIOLOGICAL DIFFERENCES BETWEEN THREE OLYMPIC RACE DISTANCES IN SHORT-TRACK SPEED SKATING

HESFORD, C., LAING, S.J., COOPER, C.E., CARDINALE, M.

BRITISH OLYMPIC ASSOCIATION

TITLE: Comparison of Physiological Differences between Three Olympic Race Distances in Short-Track Speed Skating AUTHORS: Hesford, CM.1,2, Laing SJ.1, Cooper CE.2, Cardinale, MC.1. INSTITUTIONS: 1British Olympic Medical Institute (London, UK), 2University of Essex, (Colchester, UK). PURPOSE: To compare the physiological effects at global and local muscle level of undertaking short-track speed skating race simulations over the 3 Olympic race distances. METHODS Subjects were 6 male elite short track speed skaters, all members of the Great Britain Olympic squad (age:  $22 \pm 3$  years, height:  $172.6 \pm 11.79$  cm, mass:  $70.75 \pm 12.43$  kg, mid-thigh skin fold thickness:  $6.97 \pm 1.3$

mm). Subjects performed race simulation over each Olympic distance (500m; 1000m; and 1500m) in randomized order separated by at least 24h. In addition to measurements of global oxygen consumption (VO<sub>2</sub>) and blood lactate concentration, two spatially resolved near-infrared oximeters were used to non-invasively measure the changes in both muscle tissue oxygen saturation (TSI%) and hemoglobin concentration (tHb) in the right and left vastus lateralis muscles. RESULTS Simulations were completed in  $44.82 \pm 0.41$  s (500m),  $94.95 \pm 2.08$  s (1000m) and  $151.03 \pm 4.04$  s (1500m). Post-1000m blood lactate was significantly higher than post-500m blood lactate ( $9.76 \pm 0.54$  mmol•l<sup>-1</sup> v  $6.77 \pm 0.61$  mmol•l<sup>-1</sup>,  $P=0.005$ ). Peak VO<sub>2</sub> was significantly higher during lap 1 of 500m than lap 1 of 1500m ( $49.04 \pm 5.35$  ml•kg<sup>-1</sup>•min<sup>-1</sup> v  $31.56 \pm 5.24$  ml•kg<sup>-1</sup>•min<sup>-1</sup>,  $P<0.05$ ). Race distance did not affect magnitude of maximal TSI reduction, but linear regression analysis of TSI% change during race start showed that race distance affected the speed of initial desaturation (slope values =  $-2.99 \pm 0.07$  in 500m,  $-2.42 \pm 0.09$  in 1000m, and  $-1.91 \pm 0.08$  in 1500m). Following initial desaturation, asymmetry between legs was observed in the 500m and 1000m: left leg TSI values increased throughout the race, indicating gradual muscle restoration, whereas right leg values remained stable. Single lap analysis showed consistent differences in the patterns of right and left leg tHb changes caused by specific demands of each section of lap. Greatest difference between the legs is seen during cornering, when the skater 'hangs' on the right leg. TSI asymmetry is not observed in the 1500m, during which the 'hang' phase is not generally employed. CONCLUSION: The study has highlighted the differences in right and left leg muscle saturation during the 3 race distances. The use of the portable tool to acquire local muscle measurements in vivo, in combination with the global measures which were taken, builds a more comprehensive understanding of the metabolic demands of undertaking the three different race distances. This information may have implications for athletes and coaches in terms of specificity of training, with regard to both leg asymmetry and race distance.

## ADAPTATION OF THE LÉGER'S FITNESS TEST TO JUDO

KIRBSCHUS, K.

RUHR-UNIVERSITY BOCHUM

ADAPTATION OF THE LÉGER'S FITNESS TEST TO JUDO Kirbschus, K., Kirbschus, M., Ferrauti, A. Ruhr-University Bochum, Department of Coaching Science (Bochum, Germany) Introduction The multistage 20 m shuttle run test for aerobic fitness (Léger et al. 1982) is worldwide used for endurance testing in different sports and several modifications of the test design had been published in the last two decades. The aim of the present study was to use the original beep protocol for a specific endurance test in judo by adapting the motoric demands. Methods In order to validate a maximal multistage judo shuttle run test 14 well trained judoka (age  $22.0 \pm 4.3$  yrs, BMI  $23.4 \pm 1.6$ ) and 13 4th division soccer players (age  $23.6 \pm 3.0$  yrs, BMI  $23.5 \pm 1.8$ ) completed the regular shuttle run test (SRT) and the judo adapted version (JSRT) on two occasions at least one week apart in a cross over designed order. To test the repeatability 16 Judoka repeated the JSRT twice. Adaptation of the JSRT consisted in the following criteria: The distance covered between the beeps corresponded to 8m on a judo mat. Simultaneous to the beeps the athletes have to push-up behind the line. Between two beeps one judo role should be done in a target zone between two lines. Results No differences were found between the maximum test level performance during the SRT between judoka ( $11.6 \pm 1.3$ ) and soccer players ( $11.1 \pm 1.5$ ). During JSRT judoka reached significantly higher test levels ( $9.2 \pm 1.8$ ) than soccer players ( $5.6 \pm 1.4$ ). Blood lactate concentration after exhaustion tended to be higher in judoka ( $9.1 \pm 3.3$  mmol/l) than in soccer players ( $7.1 \pm 2.0$  mmol/l). Test retest correlation of the JSRT was significant ( $r=0.900$ ) and differences in mean maximum test levels were found. Discussion The JSRT seems to be sufficient valid and reliable. We recommend this test for judoka coaches because of its practical value when using the available Test CD and the usual training surroundings. References Léger, LA & Lambert, J. (1982). A maximal multistage 20-m shuttle run test to predict VO<sub>2</sub> max. Eur J Appl Physiol Occup Physiol 49:1-12.

## MANIPULATION OF PACING PROFILES DURING SIMULATED 400M RACES IN HIGH-LEVEL JUNIOR SWIMMERS: EFFECTS ON PERFORMANCE

SKORSKI, S., FAUDE, O., WENGERT, N., MEYER, T.

UNIVERSITY OF SAARLAND

Introduction Recent research suggested that athletes develop a stable pacing profile (PP) during their career, which is recalled for similar trials (Mauger et al., 2010). However, there is only little data available whether such PP are optimal and in which way slight manipulations may have an impact on performance. Therefore, the aim of this study was to manipulate self-selected PP (PPSS) during simulated 400 m competitions in high-level junior swimmers and analyze the effects on performance. Methods 13 competitive front-crawl swimmers (4♀, 9♂, age:  $18.4 \pm 2.6$  yrs, training history:  $6.5 \pm 1.6$  yrs) performed 3 simulated 400m races. The first test was swum with a PPSS. The first 100m section of the following tests was manipulated in a randomised order: slower (PPslow:  $+2.9 \pm 1.4$ s,  $4.2 \pm 2.0\%$ ) or faster (PPfast:  $-1.9 \pm 0.8$ s,  $3.0 \pm 1.4\%$ ). 15m start time was determined by video analysis. All 100m split times were determined during each trial. Maximal blood lactate concentrations [bLa]max and heart rates [HR]max were measured for all tests. Results There was a tendency for faster average 400m times for the self-selected trials (PPSS =  $272.5 \pm 15.9$  s, PPslow =  $275.7 \pm 16.0$  s, PPfast =  $276.9 \pm 17.7$  s,  $p=0.07$ , partial eta square =  $0.20$ ). Neither [bLa]max ( $10.3$  to  $10.8$  mmol/L,  $p=0.68$ ) nor HRmax ( $177$  to  $178$ /min,  $p=0.71$ ) were significantly different between conditions. While the initial 100m was significantly slower in PPslow compared to PPSS, no differences for all further sections were observed ( $p>0.9$ ). In contrast, the faster first 100m section in PPfast resulted in slower times during the second half of the race ( $\sim 2$ s per 100m,  $p<0.02$ ). 2 subjects showed their best performance in PPfast ( $-2.9$ s) and 4 in PPslow ( $-0.2$  to  $-1.3$ s). When corrected for start time ( $7.1 \pm 0.7$ s) no difference was observed between sections in PPSS ( $p>0.18$ , even pacing). Furthermore, the first section was faster than all others in PPfast ( $p<0.001$ , fast-slow) as well as slower than the last one in PPslow ( $p=0.03$ , slow-fast). Discussion It is concluded that a PP manipulation with slower or faster first sections does not result in better performance time compared to PPSS during a 400m race in most swimmers. On average, starting slower did not enable swimmers to speed up towards the end of the race, whereas starting faster resulted in considerable performance decrements during the later sections of the race. However, single subjects showed better performance during the manipulated races, hence in some cases the PPSS might not be optimal. Future research should focus on the identification of subject characteristics that indicate which PP should be chosen to swim as fast as possible. References Mauger AR, Jones AM, Williams CA. (2010). Eur J Appl Physiol, 2010; 108 (5), 1015-23

## CARDIORESPIRATORY AND METABOLIC RESPONSES DURING MAXIMAL AND SUBMAXIMAL EGGBEATER KICKING BY WATER POLO PLAYERS

SASAKI, Y.1, TAKAGI, H.2, FUJII, N.3, TSUJI, B.1, TSUBAKIMOTO, S.2, NISHIYASU, T.2

1: UNIVERSITY OF TSUKUBA, 2: UNIVERSITY OF TSUKUBA, 3: JSPS FELLOW

**Introduction** During a water polo match, players float in the water and perform the eggbeater kick (EK) for about 1 h. The intensity of the EK depends on the situation and is especially high during contact play. The purpose of this study was to investigate the cardiorespiratory and metabolic responses during maximal and submaximal EK exercises in water polo players. **Methods** Thirteen male college-age competitive water polo players performed incremental cycling (C) and EK exercises in random order. Both exercises consisted of n•3-min exercises with 60-s recoveries until exhaustion. During EK, subjects were not allowed to use arm sculling. **Results** We found that  $\dot{V}O_{2peak}$  was significantly lower during EK than C ( $48.9 \pm 6.8$  vs.  $53.6 \pm 4.9$  ml/kg/min,  $p < 0.05$ ), as was  $\dot{V}E_{peak}$  ( $102.3 \pm 16.5$  vs.  $135.8 \pm 15.2$  l/min,  $p < 0.05$ ). We also compared heart rate (HR), minute ventilation ( $\dot{V}E$ ), tidal volume (TVE), and respiratory rate (RR) between EK and C at three levels of  $\dot{V}O_2$  (24, 36 and 48 ml/kg/min). Although HRs at all three  $\dot{V}O_2$  levels did not significantly differ between the exercises,  $\dot{V}E$ s at all three  $\dot{V}O_2$  levels were significantly lower during EK than C. In addition, TVEs were significantly greater during EK than C at the two lower  $\dot{V}O_2$  levels, while RRs were significantly lower. **Discussion** We found  $\dot{V}O_{2peak}$  during EK to be 91% of that during C in water polo players. It may be that active leg muscle mass during EK was smaller than during C. Additionally, because  $\dot{V}E_{peak}$  was lower during EK, arterial  $O_2$  content also may have been lower, contributing to the lower  $\dot{V}O_{2peak}$ .  $\dot{V}E$ s at three levels of  $\dot{V}O_2$  were lower during EK than C. Given that the thermal conductivity of water is greater than that of air, and that  $\dot{V}E$  increases with increases in core temperature during exercise (Hayashi et al. 2006), the lower  $\dot{V}E$  during EK may reflect a lower core temperature. We also found that TVEs at the two lower  $\dot{V}O_2$  levels were significantly greater during EK than C, while RRs were lower. Because buoyancy in a resting vertical position increases with increases in TVE (Von Döbeln et al. 1974), the subjects may have increased their buoyancy during EK by increasing TVE. If so, not only their leg movement (Sanders, 1999) but also their breathing is important for keeping their upper body above the water surface during EK. **References** Sanders R H. (1999). J Appl Biomech. 15, 284-291. Hayashi K, Honda Y, Ogawa T, Kondo N, Nishiyasu T. (2006). J Appl Physiol. 100, 414-20. Von Döbeln W, Holmér I. (1974). J Appl Physiol 37, 55-59.

## ANALYSIS OF PERFORMANCE INDICATORS' VARIATION DURING BEACH VOLLEYBALL MATCHES.

MEDEIROS, A.1, MESQUITA, I.1, OLIVEIRA, J.1, AFONSO, J.1, LOUREIRO, C.C.A.2

UNIVERSITY OF PORTO - FACULTY OF SPORT

**Introduction** Physiologic, functional and tactical demands of team sports have been studied, in an attempt to better understand the critical determinants of performance (Bangsbo, Mohr & Krstrup, 2006). Therefore, the purpose of this study was to analyse the variability of the acute physiologic responses, muscular power, and tactical performance in Beach Volleyball matches. **Methods** Sixteen male Brazilian beach volleyball players (aged  $28.1 \pm 6.0$  years) were analyzed in eight matches. Heart rate was measured at rest (before match) and continuously during the match. Blood lactate concentrations and vertical jump measurements were made at rest, and at the end of the 1st, 2nd and 3rd sets. Tactical performance was assessed during the match sets using the following indicators: coefficient of efficiency of performance on service, reception, distribution, spike, block and defence. The Wilcoxon matched-pairs ranks tests were used to determine differences between paired data. **Results** Blood lactate concentrations increased significantly from rest to the final of each set, (1st  $1.8 \pm 0.5$  p=0.01; 2nd  $3.5 \pm 2.3$  p<0.001; 3rd  $3.5 \pm 1.5$  p<0.001). Average heart rate increased significantly (p=0.036) from the end of the 1st set ( $146 \pm 12$ ) to the end of the 2nd set ( $150 \pm 9$ ). Moreover, an improvement in vertical jump was observed from rest ( $53.2 \pm 7.6$ ) to the end of the 1st set ( $53.8 \pm 7.5$ ; p=0.017), and between the 1st set and the 3rd set ( $55.0 \pm 7.8$ ; p=0.016). No significant differences were found for tactical performance. **Conclusions** Blood lactate concentrations does not seem to reflect the match intensity. Although heart rate values showed high variability, the set average values were stable during the match, but lower when compared to other intermittent sports, including indoor volleyball. Vertical jump and tactical performance were stable during the match. Possibly, the work-to-rest ratio during the match afforded enough time for recovery, which might explain the observed stability. **References** Bangsbo, J.; Mohr, M.; Krstrup, P. Physical and metabolic demands of training and match-play in the elite football player. Journal of Sports Sciences [S.l.], v. 24, n. 7, p. 665-674, 2006.

## THE EFFECTS OF THE DIFFERENCES OF CYCLING TIME ON ENERGY DYNAMICS AND BIOCHEMICAL MARKERS OF HEART DAMAGE FOR JAPANESE RECREATIONAL CYCLISTS

OZAKI, H.

JUNTENDO UNIVERSITY

**THE EFFECTS OF THE DIFFERENCES OF CYCLING TIME ON ENERGY DYNAMICS AND BIOCHEMICAL MARKERS OF HEART DAMAGE FOR JAPANESE RECREATIONAL CYCLISTS** Hayao Ozaki, Shinichiro Murade, Ryo Kakigi, Takashi Nakagata, Toshinori Yoshihara, Shizuo Katamoto, Hisashi Naito Juntendo University **Introduction** Prolonged cycling and running impact energy dynamics and cardiac function (Costill, 1970; Neumayr et al., 2005). However, the effects of the differences of cycling time on energy dynamics and biochemical markers of heart damage have not yet been explored. Therefore the aim of this study was to investigate them for Japanese recreational cyclists. **Methods** A total of 28 recreational cyclists, aged 18-63 years, participated in the same local enduro and were divided into 3 groups by the race time: within 1-hour group (1H, n=7), 1-2 hour group (2H, n=14), more than 4-hour group (4H, n=7). Venous blood samples were obtained from an antecubital vein before the start of the race (Pre) and immediately after the race (Post). Then insulin, non-esterified fatty acid (NEFA), heart type fatty acid-binding protein, N-terminal pro-brain natriuretic peptide (NT-proBNP), cardiac troponin T (cTnT), creatine kinase, creatine kinase MB (CK-MB), myoglobin, lactate dehydrogenase, aspartate aminotransferase, alanine aminotransferase (ALT) and  $\gamma$ -glutamyl transpeptidase ( $\gamma$ -GTP) were measured at commercially available laboratories. Blood lactate (LA) and glucose levels were evaluated with blood from a fingertip, respectively. **Results** There were not differences in all value-Pre and was a time effect in all value except ALT and  $\gamma$ -GTP. LA-Post in the 2H group ( $7.1 \pm 0.8$  mmol/l) was significantly higher than that in the 1H ( $4.8 \pm 0.8$  mmol/l) and 4H ( $2.3 \pm 0.2$  mmol/l) group. There was a significant increase in NEFA-Post for the 4H ( $1433 \pm 94$   $\mu$ Eq/L) group compared to the 1H ( $243 \pm 35$   $\mu$ Eq/L) and 2H ( $590 \pm 76$   $\mu$ Eq/L) group. cTnT-Post and CPK-MB-Post in the 4H ( $0.073 \pm 0.027$ ,  $9.2 \pm 1.9$  ng/mL) group were significantly higher than that in the 1H ( $0.005 \pm 0.002$ ,  $4.3 \pm 1.2$  ng/mL) and 2H ( $0.013 \pm 0.002$ ,  $5.4 \pm 0.5$  ng/mL) group and NT-proBNP-Post in 4H ( $99 \pm 27$  pg/mL) group was higher than that in the 2H ( $51 \pm 16$  pg/mL) group. **Discussion** LA after the race increased until 2-hour but was lower in the 4H group than 1H and 2H group. Costill (1970) has also shown the same results in running. Meanwhile, NEFA significantly increased in the 4H group after the race compared to the 1H and 2H group. Thus the differences of cycling time influenced energy dynamics in enduro.

Additionally, although there are not different in the value associated with hepatic function after the race among three groups, cTnT, CPK-MB and NT-proBNP as clinical indicators of cardiac damage significantly increased in the 4H group compared to the 1H and 2H group. Therefore, such a race over 4-hour may put great stress on cardiac system for Japanese recreational cyclists. References Costill DL (1970). *J Appl Physiol*, 28(3), 251-255. Neumayr G et al (2005). *Am J Cardiol*. 96(5), 732-735.

### BODY MASS AND SKINFOLDS IN ELITE FEMALE ROAD CYCLISTS: NORMATIVE VALUES AND TYPICAL CHANGES

HAAKONSEN, E.1,2, MARTIN, D.1, EBERT, T.1, LEE, H.1, GARVICAN, L.1, GARDNER, S.1, BARNES, C.1, BURKE, L.1

1: AIS (CANBERRA, AUSTRALIA), 2: UNIVERSITY OF QUEENSLAND (QUEENSLAND, AUSTRALIA)

**Introduction** Anthropometric characteristics of a relatively small sample of elite female cyclists have previously been described (Martin et al., 2001). However, typical changes in body mass and sum of seven skinfolds over a year of training and racing in this weight conscious population are not well documented. This study reports body mass and sum of seven skinfolds in elite female cyclists and describes the relationship between changes in these commonly monitored variables. **Methods** Anthropometric profiles were assessed in elite female cyclists from 1996 - 2010. Body mass was recorded using a calibrated scale and sum of seven skinfolds were measured in duplicate using calibrated callipers (Harpenden) as described by Norton & Olds (1996). Descriptive statistics were calculated for mass and skinfolds. Change scores for mass and skinfolds that occurred from two weeks to six months were calculated. Change scores were analysed using linear regression analysis. The percentage of change scores that deviated from the expected relationship was documented. **Results** Data from 22 female cyclists met the inclusion criteria for this study. Five scientists completed 9.6 ( $\pm 4.9$ ) anthropometric profiles. Cyclists were of a high calibre and included a former UCI number one ranked cyclist, World Cup winners, and Olympians. Mean ( $\pm$  SD) body mass was 58.91kg ( $\pm 3.86$ ) [range 56.76 ( $\pm 3.84$ ) to 61.46kg ( $\pm 3.93$ )]. Mean sum of seven skinfolds was 61.0mm ( $\pm 14.1$ ) [Range 51.0mm ( $\pm 14.1$ ) to 73.8mm ( $\pm 14.8$ )]. Change scores were examined in 17 cyclists where there was a high frequency of monitoring. Change scores were distributed as follows: 22% inc mass – inc skinfold; 42% dec mass – dec skinfolds; 19% inc mass – dec skinfolds; 16% dec mass – inc skinfold. On average, the greatest reduction in body mass was -2.4kg ( $\pm 1.0$ ) while the greatest weight gain was 2.0kg ( $\pm 1.0$ ). On average, the greatest reduction in skinfolds was -13mm ( $\pm 7$ ) and the greatest gain was 10mm ( $\pm 7$ ). Only 14% of the variance in change in mass could be explained by change in skinfolds. **Discussion** Our results indicate that ~2.0-2.5kg fluctuations in body mass and ~10-13mm fluctuations in skinfold are realistic seasonal changes in elite female cyclists. Due to our methodology, these estimates are likely conservative. Approximately one third of the change scores indicate that elite female cyclists manipulate fat free mass and fat mass independently. **References** Martin, D. T., et al. ### THE CLASSIFICATION OF CYCLISTS: A SYSTEMATIC LITERATURE REVIEW

DE PAUW, K., ROELANDS, B., DE GEUS, B., MEEUSEN, R.

VRIJE UNIVERSITEIT BRUSSEL

**Introduction** There already exists a classification of 'professional' cyclists (Jeukendrup et al, 2000), however it seems that many different classifications and criteria are used to describe a group of cyclists. The aim of this systematic literature review is to present an overview of physiological values per classification. **Methods** A systematic literature review. **Inclusion criteria:** healthy, male subjects, sufficient described group of subjects, and cycling related research. **Exclusion criteria:** articles published before 2000, n<6 subjects, age < 18 yrs, no detailed subject descriptions and groups of subjects including females or mixed groups. In literature, various definitions describe the group of subjects. We used the following most common classifications: 'untrained', 'recreationally trained', 'trained', 'well trained' and 'professional' for further analysis. **Results** Based on the above mentioned criteria 135 articles were included. The most cited parameters for subject descriptions are gender (n=81), age (n=125), body mass (n=125), height (n=101), relative and/or absolute VO2max or VO2peak (n=95), and absolute and/or relative peak power output (PPO) (n=51). 35 articles gave information concerning history and current training/competition data. According to the database, groups of subjects categorized as 'untrained', 'recreationally trained', 'trained', 'well trained' and 'professional' presented VO2max values of respectively 42.9  $\pm$  4.2, 49.2  $\pm$  5.2, 64.3  $\pm$  6.3, 65.5  $\pm$  6.1 and 74.8  $\pm$  3.6 mL/kg/min. For the absolute VO2max values of respectively 3.4  $\pm$  0.1, 3.8  $\pm$  0.3, 4.4  $\pm$  0.3, 5  $\pm$  0.3 and 5.1  $\pm$  0.2 L/min were observed. The absolute PPO values for the five categories were respectively 284  $\pm$  23, 308  $\pm$  13, 359  $\pm$  28, 406  $\pm$  52 and 456  $\pm$  47 W. For the relative VO2max significant differences between the classifications were found, except between 'trained' – 'well trained' cyclists (p=0.289). For the absolute VO2max and PPO values significant differences were observed between 'recreationally trained' – 'trained' (p=0.007; p=0.009), and 'trained' – 'well trained' subjects (p=0.005; p=0.006). **Conclusion** This systematic literature review clearly shows several overlap zones from the physiological parameters between the different classifications. A definition of a unified terminology and criteria for classification are needed. **Reference** Jeukendrup AE, Craig NP, Hawley JA. ### COMPARISON BETWEEN SPECIFIC AND UNSPECIFIC TESTING IN SWIMMING

MURA, R., MILIA, R., PINNA, M., ROBERTO, S., LOI, A., ORTU, M., MIGLIACCIO, G.M., CRISAFULLI, A.

LABORATORIO DI FISILOGIA DEGLI SPORT

**Introduction** Physiological parameters measurement is a valid tool to assess exercise capacity of athletes engaged in different types of sport activities providing that, when testing, subjects perform an exercise similar to that of their specific discipline. This concept is particularly true for sport such as swimming, since it is not simple to reproduce in the laboratory setting the specificity of swimming movements. This study was set to compare results from three unspecific exercise testing procedures [arm-cranking (AC), cycling (CY), and running (RU)] with those obtained from one specific swimming (SW) test in a swimming pool. **Methods** 12 athletes at Italian national level (age 19.2  $\pm$  2.8 years, weight 68.9  $\pm$  5.7 Kg, and height 177.3  $\pm$  6.1 cm) agreed to participate in this investigation. They underwent three laboratory standard incremental exercise tests up to exhaustion using three different protocols and ergometers: AC, CY, and RU. During all tests data of maximal oxygen uptake (VO2max), maximal heart rate (HRmax), and anaerobic threshold (AT) were gathered. These data were then compared to those obtained from an incremental SW test while subjects wore a portable metabolic device (VO2000, MedicGraphics, USA) and exercised against an elastic rope which was tied at one extremity. The workload was controlled by a dynamometer. **Results** Statistics revealed that SW testing provided higher values of VO2max and VO2 at AT with respect to AC and CY testing while no difference was found between SW and RU. Moreover, HRmax was lower during SW than during all the other exercise testing. **Discussion** Results from the present study reveal that, among the various testing procedures employed, only RU testing provides VO2 values which

are similar to those obtained from specific SW testing. However, none of the unspecific testing protocols provide data that can be interchangeably used instead of SW testing. Thus, it is strongly recommended the use of specific SW testing to assess swimmers exercise capacity. References Holmér I, (1992) *Ann Physiol Anthropol*, 11(3); 269-76. ## ASSESSMENT, MONITORING AND CONTROL OF HIGH LEVEL ROLLER SPEED SKATERS

MARINO, F., VALBUENA, L.H., MUJICA, J.G.

INDEPORTES ANTIOQUIA

Introduction Roller Speed Skating has gained great popularity in our country due to many results in world championships and other competitions where Colombia has been winner. This involves several factors: Organization of regional tournaments by National Federation, big volumes of training loads and many competitions, Sports Medicine and Applied Science's evaluations, all this has guaranteed an adequate preparation to competition. Methods We want to show some results of monitoring, evaluation and control we usually do to Colombian's skaters which show the reasons they are better of the world currently. Anthropometric characteristics and evaluation of aerobic and anaerobic power show a well-trained athlete's group for achievement of their objectives. The evaluations have been made in Physiology Laboratories of Indeportes Antioquia in Medellin and High-performance Center of Coldeportes Nacional in Bogotá, Colombia. Results The average and standard deviation for men and women's group were: Size:  $172,9 \pm 4,1$  cm;  $160,8 \pm 4,3$ . Weight:  $67,9 \pm 7,6$  kg;  $57,9 \pm 3,0$  kg. %Fat:  $7,3 \pm 0,9$ ;  $14,3 \pm 2,6$ %. %Lean Body Mass:  $92,8 \pm 0,9$ %;  $85,7 \pm 2,6$ %. Somatotype X: 0,7; -1,3. Y: 5,0; 2,8. Wingate Test:  $14,7 \pm 2,7$  watt;  $9,5 \pm 0,6$  watt. VO2max.  $63,8 \pm 9,3$  ml/kg.min;  $55,6 \pm 2,8$  ml/kg.min. Bosco Test:  $29,0 \pm 7,5$  watt/kg;  $22,5 \pm 4,4$  watt/kg. Discussion These results demonstrate great preparation of Colombian's skaters to World Championship. Also, these results added to a great volume in training loads and very good sports technique, allow skating is claimed as an option to show our country like sports potency in this modality. #### UNIQUE EFFECTS OF INTERMITTENT EXERCISE AND TIME OF DAY ON RECOVERY BLOOD PRESSURE "KINETICS"

THOMPSON, A.1, JONES, H.1, CHESTER, N.1, LEWIS, N.1, MARRIN, K.1,2, ATKINSON, G.1

1: RISES, LJMU, UK. 2: EDGE HILL UNIVERSITY, UK.

Introduction Exercise is an important intervention in blood pressure (BP) control. Previously, we reported that intermittent exercise mediates a greater overall reduction in recovery blood pressure (BP) than continuous exercise, irrespective of time of day (Jones et al., 2009). However, the exact minute-by-minute time-course in BP reduction was not described and the amount of sleep prior to the morning and afternoon exercise times was not controlled in this previous study. Therefore, we investigated the effects of intermittent exercise on minute-by-minute BP recovery at two times of day while controlling for prior sleep and posture. We hypothesised that BP falls in a cumulative manner during the recovery phases of intermittent exercise. Methods Following an estimation of required statistical power based on previous research, a sleep- and posture-controlled protocol (Jones et al., 2008) was completed at 06:30 and 16:30 h by 9 men, aged (mean $\pm$ SE)  $27\pm 9$  years. At each time of day, participants completed 3x10 min bouts of semi-supine cycling (60% peak power output) with each bout separated with 10 min of passive recovery. Recovery period 3 was followed by 10 min of supine rest. Systolic and diastolic BP and mean arterial pressure (MAP) were measured continuously from the middle finger (Finometer). Data were analysed using repeated-measures linear mixed models and are described as mean $\pm$ SE. Results Baseline BP was unaffected by time of day ( $P>0.05$ ). Recovery MAP differed between times of day ( $P=0.003$ ) and recovery periods ( $P=0.002$ ). MAP did not differ significantly ( $P=0.57$ ) between recovery periods 1 ( $88\pm 3$  mmHg) and 2 ( $88\pm 3$  mmHg) but was significantly ( $P<0.0005$ ) lower in recovery period 3 ( $82\pm 3$  mmHg). For the first min of recovery period 1, MAP was  $20\pm 6$  mmHg higher in the morning ( $P<0.005$ ), but declined more rapidly than in the afternoon. The time-course of MAP was much less variable in recovery periods 2 and 3. Discussion These data provide the first evidence that BP reduces during the recovery periods of intermittent exercise in a non-linear cumulative fashion. Even when prior sleep is controlled through a novel protocol, BP is highest during the first min of the first recovery period in the morning, but this 'shock effect' dissipates during subsequent recovery periods. Given the strong relationship between changes in BP in the morning and risk of stroke and cardiovascular events (Kario, 2010), our results have important implications for the prescription of exercise in the control of BP. #### EFFECT OF TIME OF DAY ON UPPER AND LOWER BODY HIGH INTENSITY EXERCISE PERFORMANCE

MCCORMICK, M.C., BAKER, J.

UNIVERSITY OF THE WEST OF SCOTLAND

Introduction Circadian rhythms influence many physiological functions of the human body, however their impact on high intensity exercise remains inconclusive. Previous studies which have investigated high intensity leg cycle ergometry include Reilly & Down (1992) who reported no time of day effect on performance when subjects were tested at 6 time points in a 24hr period. However a similar study by Hill & Smith (1991) found power output (PO) to be higher in the afternoon than in the morning. In addition there is recent evidence which demonstrates that the upper body plays a significant role in the production of PO during high intensity leg cycle ergometry (Baker et al 2001). Therefore the objective of this study was to assess peak power of the upper and lower body over a 12hr period and to establish if

they follow similar patterns of diurnal variation. A secondary aim was to assess the impact of the subject's motivation on performance. Methods 11 male subjects ( $22.9 \pm 2.6$  yrs;  $182 \pm 0.06$  cm;  $80.43 \pm 14.39$  kg) were tested over a 12hr period (0800-2000h). Every hour, on the hour, subjects performed a 10s maximal leg cycle ergometry test; every hour, on the half hour, they performed a standing broad jump (SBJ), maximal hand grip test (HG) and vertical jump (VJ). Tympanic temperature, blood pressure, heart rate (HR) and EFI scores (Exercise-Induced Feeling Inventory) were recorded at regular intervals. Results The main results show that there were no significant differences across the 12hr period for peak power produced by the upper or lower body ( $P > 0.05$ ). However PO of the lower body (SBJ, VJ) and PO during high intensity cycling along with positive engagement all peaked at 1900h. HR immediately following the 10s maximal cycling was found to be significantly higher at 1900h ( $P < 0.05$ ) compared to all other time points (except 1700, 1800h). Discussion-Conclusion The results show that PO is not significantly affected by the time of day therefore indicating that there is no circadian rhythm in high intensity exercise. However there is a suggestion that lower body PO is somewhat affected by motivational levels of subjects as evidenced by peak values for positive engagement coinciding with peaks observed for PO. It is likely subjects were highly motivated at 1900 as this was the last trial of the day. These findings suggest that to ensure true peak performance during high intensity exercise, individuals must be highly motivated. References Baker J et al (2000). ### CIRCADIAN VARIATION IN HYPERTHERMIC HYPERVENTILATION DURING PROLONGED EXERCISE IN THE HEAT

TSUJI, B.1, HONDA, Y.2, FUJII, N.3, KONDO, N.4, NISHIYASU, T.2

1: UNIVERSITY OF TSUKUBA, 2: UNIVERSITY OF TSUKUBA, 3: JSPS FELLOW, 4: KOBE UNIVERSITY

Introduction Hyperthermia during exercise causes skin vasodilation and sweating (two thermoregulatory responses), as well as hyperventilation (Fujii et al. 2008). Notably, these thermoregulatory responses during exercise are influenced by circadian variation in resting core temperature. It is unclear, however, whether the same is true of hyperthermic hyperventilation. We therefore examined whether hyperthermic hyperventilation during prolonged exercise is altered by circadian variation in body temperature. Methods Ten male subjects performed a cycle exercise at 50% of peak oxygen uptake in the heat ( $37^{\circ}\text{C}$  and 50% RH) at 6:00 (AM) and 18:00 (PM). Before each exercise, the subjects were immersed for 25 min in water at  $18^{\circ}\text{C}$  to detect the esophageal temperature (Tes) threshold for hyperventilation (Tsuji et al. 2009). Results The Tes thresholds for increases in the sweat rate (SR) and forearm vascular conductance (FVC) were higher at PM than AM ( $P < 0.05$ ), but there was no difference in the respective slopes of the SR-Tes and FVC-Tes relations at the two times. The Tes threshold for hyperventilation was higher at PM than AM ( $37.2 \pm 0.7$  vs.  $36.6 \pm 0.6^{\circ}\text{C}$ ,  $P < 0.05$ ), and the slope of the minute ventilation (VE)-Tes relation at Tes above the threshold was greater at PM than AM ( $16.5 \pm 5.0$  vs.  $10.8 \pm 5.5$  L/min/ $^{\circ}\text{C}$ ,  $P < 0.05$ ). The Tes threshold for increases in respiratory frequency (f) was also higher at PM than AM ( $37.4 \pm 0.6$  vs.  $36.7 \pm 0.7^{\circ}\text{C}$ ,  $P < 0.05$ ), and the slope of f-Tes relation tended to be greater at PM than AM. Tidal volume declined steadily without a threshold in response to increasing Tes at both AM and PM. Discussion Our observation of circadian rhythm-related changes in two thermoregulatory responses is consistent with previous findings. Like those thermoregulatory responses, the Tes threshold for hyperventilation shifted to a higher temperature from AM to PM. However, the slope of VE-Tes relation was greater at PM than AM, which is different from the thermoregulatory responses. Furthermore, the Tes threshold for increases in f was nearly identical to that for increases in VE, and the slopes of the f-Tes and VE-Tes relations were both greater at PM, suggesting changes in hyperthermic hyperventilation are mainly attributable to changes in f. In conclusion, those results suggest that humans exhibit circadian variation in hyperthermic hyperventilation during prolonged exercise in the heat. ### GENDER INFLUENCE ON SKIN TEMPERATURE AT REST AND DURING EXERCISE IN THE COLD : THE ROLE OF SUBCUTANEOUS FAT

FOURNET, D.1, REDORTIER, B.2, HAVENITH, G.1

1. EERC (LOUGHBOROUGH UNIVERSITY, UK) 2. OR (VILLENEUVE D'ASCQ, FRANCE)

Introduction Subcutaneous fat affects skin temperature (Tsk) through the conductive heat transfer between the body core and the skin. Vasoconstriction induced by cold exposure maximises the insulatory benefits provided by subcutaneous fat (Rennie, 1988). Higher amounts of body fat are commonly found in females and this has been suggested to impact thermoregulatory responses at rest and during exercise (Wagner and Horvath, 1985). Gender differences in fat patterning may also explain patterns of Tsk distribution. The aim of the study was therefore to investigate the role of subcutaneous fat on overall and local Tsk responses. Methods Nine males and females of similar fitness ( $53.7$  vs  $50.3$  mL/min/kg, NS) participated in the experiment. Skinfold thickness at 24 body sites was measured to assess local fat distribution and predict overall body fat percentage (%BF). Participants were asked to rest for a 5 min period followed by 40 min of running at 70%  $\text{VO}_{2\text{max}}$  in a semi nude condition at  $10^{\circ}\text{C}$ . Whole-body skin temperature was recorded by infrared thermography before (PRE) and immediately after running (POST). Body maps of Tsk patterns for both genders were obtained using an image processing technique under MATLAB. A specific segmentation of local Tsk was also performed to match the location of local skinfold values. Results Females had a significantly higher %BF than males and exhibited a lower overall mean Tsk ( $-2^{\circ}\text{C}$  at PRE,  $p < 0.01$  and  $-1.5^{\circ}\text{C}$  at POST,  $p < 0.05$ ). Mean Tsk was correlated to %BF at PRE ( $r = -0.7$ ,  $p < 0.01$ ) but the absolute metabolic rate of exercise was the main predictor at POST ( $r = 0.7$ ,  $p < 0.01$ ). Although absolute Tsk decreased during exercise, patterns of Tsk distribution were relatively constant and similar for males and females. Many local Tsk differences were significant between genders, especially in the legs and arms. Within participants distribution of Tsk was not correlated to local skinfold thickness. Only for the anterior torso in males at POST such a relation was found. ( $r = -0.7$ ,  $p < 0.05$ ). Discussion Subcutaneous fat only partly influenced overall and local Tsk responses in the groups studied. Metabolic response associated to cold and exercise (Havenith, 2001) may largely produce the overall gender difference in mean Tsk. Locally, it can be hypothesized that the insulation provided by poorly perfused muscles at rest and during exercise (Rennie, 1988) also contribute to the Tsk distribution together with local skin blood flow and morphological factors. Similarities in body maps of Tsk patterns for both genders represent a novel finding. **EXERCISE IN COLD AIR INCREASED THE H<sub>2</sub>O<sub>2</sub> RELEASE IN EXHALED BREATH CONDENSATE**

MAREK, E.1, VOLKE, J.1, MUECKENHOFF, K.2, MAREK, W.2, PLATEN, P.1

RUHR-UNIVERSITY BOCHUM

**Introduction:** Many publications indicated that winter athletes have hypersensitive bronchial systems and symptoms like bronchoconstriction and changes in the epithelial cells caused by the inhalation of cold and dry air. Therefore exhaled breath condensate (EBC) is interesting because it contains a number of mediators which arise from the bronchial system. The aim of this study was to determine the influence of constant exercise combined with cold air on the H<sub>2</sub>O<sub>2</sub> release as a marker of airway inflammation in exhaled breath. **Method:** Twelve healthy males (23.1±1.5 years) were randomly assigned at 2 different days (with 1 day rest) to perform one 50 min run (75–80% of their maximum heart rate) under normal (N) laboratory (18.1±1.1°C) and one under cold (C) field conditions (-15.2±3.1°C) Before and immediately after each run EBC was collected from 100L of exhaled air under laboratory conditions. Hydrogen peroxide concentration was analyzed using a EcoCheck amperometer (FILT, Berlin). In further analysis release per minute and theoretical release for the total amount of water from 100L exhaled breath were calculated. **Results:** Prior to the two runs H<sub>2</sub>O<sub>2</sub> concentrations were 145.0±31.1 (N); 160.0±49.1nmol/L (C) and theoretical release 70.3±37.1 (N); 82.6±27.1pmol/min (C) (p>0.05). After both conditions a significant increase of H<sub>2</sub>O<sub>2</sub> concentration from 243.0±43.8nmol/L (N) and 420.3±49.1nmol/L (C) (p<0.001) together with an increase in the theoretical release from 178.9±38.1pmol/min (N) and 318.3±35.2pmol/min (C) (p<0.001) was detected. **Conclusion:** The release of H<sub>2</sub>O<sub>2</sub> into the EBC has been shown under resting conditions and after exercise. Concentration and release sig. increased after exercise in cold air compared to resting and laboratory conditions and indicates an increase of inflammatory and oxidative stress. A association between H<sub>2</sub>O<sub>2</sub> and bronchial hypersensitivity should be investigated in further studies.

**HYPOXIA AUGMENTS THE OSCILLATORY BLOOD FLOW PATTERN IN THE NONWORKING LIMB DURING INCREMENTAL EXERCISE**

IWAMOTO, E.1, KATAYAMA, K.2, OSHIDA, Y.2, ISHIDA, K.2

NAGOYA UNIVERSITY

**Introduction** Regular aerobic exercise augments conduit vessel function. Interestingly, exercise-induced increases in vascular function have been observed in nonactive limbs, e.g., the forearm in response to cycling. A recent study revealed that an increase in mean blood flow and a marked oscillatory blood flow pattern appeared in nonworking limb during normoxic exercise, and these are thought to augment vascular function (Green et al. 2005). Exercise in hypoxic condition is associated with large changes in central hemodynamics and peripheral vascular resistance in nonactive limbs, and thus it is hypothesized that blood flow pattern would change, i.e., greater antegrade and retrograde blood flows, during hypoxic exercise. The aim of present study was to elucidate the change in the oscillatory blood flow in nonworking limb during incremental exercise in hypoxia. **Methods** Eight males participated in this study. Two maximal incremental exercise tests were conducted on a semi-recumbent cycle ergometer while breathing normoxic (inspired oxygen fraction (FIO<sub>2</sub>) = 0.21) or hypoxic gas mixture (FIO<sub>2</sub> = 0.12). The exercise began at an initial power output of 30 W, and workload was increased by 30 W every 2 min until exhaustion. Brachial blood velocity and arterial diameter were recorded simultaneously using Doppler ultrasonography, and the blood flows were calculated. **Results** Exercise induced progressive increases in antegrade and retrograde blood flows during incremental exercise in normoxia and hypoxia. The magnitude of changes in antegrade and retrograde blood flows during exercise in hypoxia were significantly (P<0.05) greater than normoxia (normoxia vs. hypoxia, antegrade blood flow at 150 W: 171.1±12.5 vs. 193.5±15.4 ml/min and retrograde blood flow at 150 W: -90.2±7.7 vs. -130.9±10.7 ml/min, mean±SE). **Discussion** It has been supposed that an increase in antegrade flow may be an important modulator of the acute effect of exercise on endothelial function (Green et al. 2011). Therefore, it is assumed that hypoxic exercise may present a more potent stimulus to endothelium in conduit arteries in nonactive limbs. On the other hand, there is also some evidence that retrograde flow may decrease the beneficial effect (Thijssen et al. 2009), and thus further studies are needed to test the assumption. Our results suggest that hypoxia has a significant impact on the oscillatory antegrade and retrograde blood flow pattern in the nonworking limbs during incremental exercise. **References** Green DJ et al. (2005) J Physiol, 562:617–628. Green DJ et al. (2011) Exp Physiol, 96:57–70. Thijssen DHJ et al. (2009) Hypertension, 53:986–992.

**SUPRASPINAL FATIGUE AFTER HYPOXIC AND NORMOXIC EXERCISE IN HUMANS**

GOODALL, S., GONZÁLEZ-ALONSO, J., BARKER, H., ALI, L., ROSS, E., ROMER, L.

CENTRE FOR SPORTS MEDICINE AND HUMAN PERFORMANCE, BRUNEL UNIVERSITY, UK

Cerebral O<sub>2</sub> delivery has been proposed to limit exercise tolerance (Rasmussen et al. 2010), but the role of supraspinal processes to fatigue in hypoxia is unknown. We tested the hypothesis that the contribution of supraspinal fatigue to task failure would be exacerbated after locomotor exercise in acute severe hypoxia compared to normoxia and that any such change would be related to a reduction in cerebral O<sub>2</sub> delivery. Nine competitive male cyclists (mean ± S.D. maximum O<sub>2</sub> uptake 61.1 ± 4.6 ml•kg<sup>-1</sup>•min<sup>-1</sup>) completed three exercise trials on a cycle ergometer at 77% of peak workload: 1) to the limit of tolerance in acute hypoxia (HYPOX-TLM; inspired O<sub>2</sub> fraction = 0.13, arterial O<sub>2</sub> saturation = 78%); 2) for the same duration as HYPOX-TLM but in normoxia (NORM-ISO; 0.21, 98%); and 3) to the limit of tolerance in normoxia (NORM-TLM; 0.21, 96%). Before and immediately after each trial, twitch responses to supramaximal femoral nerve stimulation and transcranial magnetic stimulation were obtained to assess neuromuscular and cortical function, respectively. Throughout each trial, cerebral oxygenation (frontal cortex) and cerebral blood flow velocity in the middle cerebral artery (CBFV) were assessed using near-infrared spectroscopy and transcranial Doppler sonography, respectively. Cerebral O<sub>2</sub> delivery was calculated as the product of arterial O<sub>2</sub> content and CBFV. Exercise time declined by 54% in HYPOX-TLM compared to NORM-TLM (3.6 ± 1.3 vs. 8.1 ± 2.9 min; p < 0.001). Maximum voluntary force and potentiated quadriceps twitch force were decreased below baseline after exercise in each condition; the decreases were greater in HYPOX-TLM compared to NORM-ISO (p < 0.001), but were similar in HYPOX-TLM compared to NORM-TLM (p > 0.05). Cortical voluntary activation also decreased after exercise in each condition; however, the decline in HYPOX-TLM (-17%) was greater (p < 0.05) compared to both NORM-ISO and NORM-TLM (-5 and -8%, respectively). The reductions in cortical voluntary activation occurred in parallel with reductions in cerebral oxygenation and O<sub>2</sub> delivery. The results indicate that the decrease in exercise tolerance in acute hypoxia is due, in part, to supraspinal fatigue, possibly as a consequence of inadequate O<sub>2</sub> delivery to the brain. **References** Rasmussen, P., Nielsen, J., Overgaard, M., Krogh-Madsen, R., Gjedde, A., Secher, N.H. and Petersen, N.C. (2010). Reduced muscle activation during exercise related to brain oxygenation and metabolism in humans. Journal of Physiology 588, 1985–1995.

## INFLUENCE OF EXERCISE DURATION ON O<sub>2</sub> SATURATION AND ITS HETEROGENEITY AMONG THE LEG MUSCLES

TAKAGI, S., KIME, R., MURASE, N., ANJO, M., SATO, A., KATSUMURA, T.

TOKYO MEDICAL UNIVERSITY

**Introduction** In general, blood flow increases in relation to local metabolic rate, and the O<sub>2</sub> balance is distributed heterogeneously between and within skeletal muscles during exercise (Kalliokoski et al., 2001). Exercise intensity is an important factor to determine heterogeneity of O<sub>2</sub> saturation in skeletal muscles (SmO<sub>2</sub>) during incremental cycling (Kime et al., 2001). However, it is unknown whether exercise duration, especially during steady state exercise, influences SmO<sub>2</sub> and its heterogeneity. **Methods** Ten healthy young males performed bicycle exercise at 30%, 50%, and 70%VO<sub>2peak</sub> for 30 min. Pulmonary O<sub>2</sub> uptake (pVO<sub>2</sub>) was monitored continuously during the experiments. The SmO<sub>2</sub> was monitored at the belly of vastus lateralis (VL), rectus femoris (RF), and vastus medialis (VM) muscle by near infrared spatial resolved spectroscopy (NIRSRS). To examine heterogeneity of the SmO<sub>2</sub> saturation in a single muscle, an additional NIRSRS probe was placed on a proximal point of 30% of the length between the patella and the greater trochanter, from the belly of VL muscle. Fat layer thickness on each measurement site was measured to evaluate the accurate SmO<sub>2</sub> values using an ultrasound device. As an index of SmO<sub>2</sub> heterogeneity within and between muscles, coefficients of variation (CV) of values of each muscle were calculated for 3-6 min and 27-30 min. **Results** As exercise continued, the mean SmO<sub>2</sub> of the three muscles significantly increased at 30%VO<sub>2peak</sub>, decreased at 70%VO<sub>2peak</sub> (P<0.05), and maintained at 50%VO<sub>2peak</sub> (P=0.5). Although significant differences were observed for the mean SmO<sub>2</sub> at the end of exercise, the CV of SmO<sub>2</sub> between muscles did not change over the trial at all intensities. Conversely, in a single muscle, significant main effect over time was observed by ANOVA analysis and the CV significantly increased at 70%VO<sub>2peak</sub>. Changes of CV within muscle were positively correlated with changes of pVO<sub>2</sub> at 30% (r=0.8), 50% (r=0.4), and 70%VO<sub>2peak</sub> (r=0.5). **Discussion** The SmO<sub>2</sub> heterogeneity between the leg muscles was relatively maintained during steady state exercise at mild- to severe-intensity although exercise duration impacted the mean SmO<sub>2</sub> itself according to exercise intensity. These results may be attributed predominantly to compensation by surrounding muscles. In addition, time effects were observed for regional difference of SmO<sub>2</sub> within VL muscle. These results suggest that the disparities in the O<sub>2</sub> balance are associated with increased muscle O<sub>2</sub> consumption and the marked disparities may be due to the recruitment of additional muscle fibers. **References** Kalliokoski et al. ## THE EFFECT OF PRE-COOLING AND PASSIVE HEATING ON PACING STRATEGIES AND INTERMITTENT-SPRINT PERFORMANCE IN TEAM SPORT ATHLETES

SKEIN, M., DUFFIELD, R., MARINO, F.E., CANNON, J.

CHARLES STURT UNIVERSITY

**Introduction** Team sport athletes often engage in pre-cooling prior to exercise in the heat to reduce thermoregulatory strain and improve performance. Conversely, warm-up practices are used amongst athletes to increase endogenous temperature and improve subsequent high-intensity exercise performance. This paradox in pre-exercise interventions raises questions concerning which thermal state is optimal for subsequent intermittent-sprint performance. Therefore, this study examined the effects of pre-exercise cooling and heating on pacing and intermittent-sprint performance in the heat. **Methods** Ten male, team-sport athletes completed three randomized conditions including, a thermo-neutral environment (CONT); whole body submersion in an ice-bath (ICE) and passive-heating in a hot environment (HEAT) prior to 50min intermittent-sprint exercise (ISE) in the heat (31 ± 1°C). Exercise involved repeated 15 m maximal sprints and self-paced exercise of varying intensities (hard running, jogging, walking, and bounding). Performance was measured by sprint times and total distances covered (TDC), and pacing strategies were assessed via distance covered during 10min phases of the ISE. 15 maximal contractions were performed to determine maximal voluntary torque (MVT), activation (VA), and twitch contractile properties (TCP). Physiological measures included heart rate (HR), core (Tcore) and skin (Tskin) temperatures, physiological strain index (PSI), capillary blood, and perceptual ratings. **Results** Mean sprint times, especially during the initial 10min, were slower during ICE compared to HEAT (P<0.05). TDC was not different between conditions but less distance was covered during HEAT in the final 10min compared to ICE and during 31-40min compared to CONT (P<0.05). Post-ex MVT was reduced within CONT and HEAT, and VA was higher post-intervention and post-ex during ICE. Peak torque and relaxation rates were improved post-intervention during HEAT compared to ICE. Finally, HR, Tcore, Tskin and PSI during exercise were lower in ICE compared to CONT and HEAT (P<0.05). **Conclusion** Initial sprint performance was faster following HEAT and slowed by ICE, possibly due to altered contractile properties at the start of exercise. Conversely, pre-cooling maintained endurance performance later in the protocol, while HEAT resulted in greater performance declines. ICE maintained MVT and VA post-exercise compared to HEAT, suggesting improved skeletal recruitment. Accordingly, passive heating augmented initial sprint times yet reduced pacing strategies later in the protocol, while pre-cooling reduced cardiovascular and thermoregulatory strain and allowed for selection of higher exercise intensities throughout the protocol.

## HEAT LOSS RESPONSES DURING PASSIVE HEATING WITH DIFFERENT TYPES OF PHYSICAL TRAINING

AMANO, T.1, KOGA, S.2, INOUE, Y.3, KONDO, N.1

GRADUATE SCHOOL OF HUMAN DEVELOPMENT AND ENVIRONMENT, KOBE UNIVERSITY

1: Kobe University (Kobe, Japan), 2: Kobe Design University (Kobe, Japan), 3: Osaka International University (Osaka, Japan) **Introduction** Endurance training improves heat loss responses, as demonstrated by the lower core temperature threshold and the higher slope of heat loss responses (Nadel et al., 1974). In addition, it has been observed that the sweating rate during cycling in the heat is greater in the order of endurance runners, sprinters, and untrained individuals (Irion, 1987). However, it is unknown whether the core temperature threshold and slope of the heat loss responses differ between types of physical training. Thus, we conducted passive heating to investigate heat loss responses in distance runners, sprinters, and untrained men. **Methods** Nine distance runners, 11 sprinters and eight untrained men rested in the supine position with water perfusion suits in a climatic chamber that was regulated at an ambient temperature of 27°C and relative humidity of 50%. After thermoneutral conditions for 50 min, hot water was perfused into the suits for 50 min to increase oral temperature by 1°C. The sweating rate and skin blood flow on the chest, forearm, thigh and palm were measured continuously during the passive heating, and the mean values of sweating and skin blood flow from non-glabrous skin sites were calculated. **Results** The oral temperature threshold for onset of the mean sweating response in distance runners was significantly lower than that of sprinters and untrained men (P<0.05), and the slope for sweating was significantly higher in distance runners than in untrained men (P<0.05). The oral temperature threshold for onset of mean cutaneous vasodilation in distance runners was only significantly lower than that of sprinters and untrained men (P<0.05). **Discussion** The results in this study suggest that the training of distance runners lowers the

oral temperature threshold for the onset of sweating and cutaneous vasodilation, and increases the slope of sweating during passive heating. In contrast, training of sprinters does not affect the oral temperature threshold and the slope of the heat loss responses during passive heating. Increases in core temperature during exercise are important for improvement of the heat loss responses (Pandolf, 1979); therefore, we consider that the different levels of increase in core temperature during daily training sessions between distance runners and sprinters may affect the improvement of heat loss responses during passive heating. ## THE EFFECT OF POST-EXERCISE COLD WATER IMMERSION ON CONSECUTIVE DAYS CYCLING PERFORMANCE AND HEART RATE VARIABILITY

STANLEY, J.1,2, BUCHHEIT, M.3, PEAKE, J.1,2

THE UNIVERSITY OF QUEENSLAND

1: The University of Queensland, School of Human Movement Studies (Brisbane, Australia), 2: Centre of Excellence for Applied Sport Science Research, Queensland Academy of Sport (Brisbane, Australia), 3: ASPIRE, Academy of Sports Excellence (Doha, Qatar) Introduction We investigated the effect of daily post-exercise cold water immersion (CWI) during three consecutive days of intensive training on cycling performance and heart rate variability (HRV). Methods Five trained cyclists randomly completed 3 d of intensive training including either a 5-min post-training CWI recovery or not (PAS), and performed recovery based training for the following 2 d. On each day of intensive training, cyclists completed a training session lasting 114 min that included 66 maximal effort sprints and a total of 9 min of sustained effort (time trial; TT). Performance (mean power for sprints; total work for TT), heart rate (HR), and rating of perceived exertion (RPE) were assessed during each session. HRV (natural logarithm of the square-root of mean squared differences of successive R-R intervals; Ln rMSSD) was monitored (1) on waking each day of intensive training and for the following 3 d, and (2) 5 min post-recovery intervention during the intensive training period. Perceptions of recovery were assessed in the morning before training, and prior to sleep on each day of intensive training. Effects were examined using magnitude-based inferences. Results CWI resulted in very likely higher post-recovery intervention Ln rMSSD on day 1 (difference [90% confidence limits]; 29.2% [8.4;54.1]) and 2 (27.3% [11.8;45.1]), and almost certainly higher Ln rMSSD on day 3 (23.7% [18.5;29.1]). CWI was associated with almost certainly lower tiredness prior sleeping on day 2 (-26.0% [-32.3;-19.1]) and likely lower on day 3 (-20.5% [-34.9;-2.8]). Compared with PAS, CWI had unclear effects on changes from day 1 on sprint and TT performance, mean session HR, mean session RPE, and waking Ln rMSSD. A moderate negative relationship was observed between changes compared with day 1 in waking Ln rMSSD and changes in TT performance ( $r = -0.47$  [-0.72;-0.12]). Unclear relationships were observed between the changes compared with day 1 in waking Ln rMSSD and changes in sprint performance, post-recovery intervention Ln rMSSD and perceived tiredness, next day waking Ln rMSSD and perceived tiredness. Conclusion CWI enhanced cardiac vagal reactivation and reduced perceived tiredness post-exercise, however, the effect of CWI on performance and waking cardiac vagal activity during and following a period of intensive training remains unclear. The implication of waking cardiac vagal activity on exercise performance warrants further investigation.

## CARDIORESPIRATORY AND THERMAL RESPONSES TO COMBINED HYPOXIC AND THERMAL CHALLENGE

CRIGHTON, B., FLOWER, D., IMPEY, S., LANGAN-EVANS, C., MOLPHY, J., MORGAN, C., PARRY, S., SARGEANT, A., WHITE, A., CABLE, N.T., HULTON, A.

LIVERPOOL JOHN MOORES UNIVERSITY

Cardiorespiratory and thermal responses to exercise in the heat are elevated compared to exercise in the cold (Galloway & Maughan, 1997), and exercise in hypoxic conditions also causes an exaggerated cardiorespiratory response compared with sea level (Reeves et al. 1992). As athletes, are often exposed to the combined challenge of exercise in hypoxic and hot conditions, the aim of this study was therefore to investigate the combined effect of these challenges on the cardiorespiratory and thermal response to exercise. Nine healthy well trained males participated in the ethically approved study. Following assessment of VO<sub>2</sub> peak on a recumbent cycle ergometer, subjects attended the laboratory on 3 separate occasions and exercised for 15 mins at 70% VO<sub>2</sub> peak in 3 climatic conditions; SL at 32°C, 2300m at 18°C and 2300m at 32°C. Respiratory data (VE, Bf, Tv) were calculated from expired gas collection. HR and SaO<sub>2</sub> were measured using Dynamap. Rectal temperature (RT) was measured using a grant thermometer and skin temperature measured at 4 sites using squirrel thermistors and data logger. Sweat production rate was measured by changes in nude body mass and urinary osmolality assessed by osmometry. Statistical differences were assessed by two way ANOVA with repeated measures. There was no significant difference ( $p > 0.05$ ) in RT between the conditions, although there was a significant effect of time ( $p < 0.05$ ). There was no significant ( $p > 0.05$ ) effect of time of skin temperature, but there was a significant condition effect ( $p < 0.05$ ) and interaction ( $p < 0.05$ ). Mean ( $\pm$ SD) skin temperature values before exercise for SL at 32°C, 2300m at 18°C and 2300m at 32°C, were  $32.88 \pm 0.88$ ,  $32.87 \pm 0.70$  and  $30.06 \pm 1.26$  respectively alternating to levels of  $34.22 \pm 0.80$ ,  $33.91 \pm 0.98$  and  $28.04 \pm 1.31$  after the 15 minute exercise protocol. There was no significant difference in sweat production rate between the three conditions as ( $p > 0.05$ ). There was significant main effect of VE between conditions ( $p < 0.05$ ) and across time ( $p < 0.05$ ). SaO<sub>2</sub> showed significant main effects across time ( $p < 0.05$ ) and between conditions ( $p < 0.05$ ) with mean ( $\pm$  SD) values of  $97.33 \pm 0.57$  (SL at 32°C),  $93.25 \pm 2.83$  (2300m at 18°C) and  $93.17 \pm 3.01$  (2300m at 32°C). There was also a significant interaction ( $p > 0.05$ ). HR showed a significant effect over time ( $p < 0.05$ ). This data suggests that the combined influence of exercise at altitude and in the heat causes an altered respiratory response but no difference in thermal strain, compared with either heat or altitude alone. It would be intriguing to examine these responses in exercise bouts of extended duration. Galloway S. & Maughan, R. (1997). ## RELATIONSHIP BETWEEN SLEEP HABITS AND MENTAL HEALTH IN SPORT CLUB MEMBERS OF ELDERLY

SASAKI, H.1, ODA, S.2

HOKUSHO UNIVERSITY

Introduction: The QOL for elderly people has two aspects; physical health and mental health. Exercise and sleep habits maintain and promote physical and mental function (Weinstein et al., 2007, King AC et al., 2008). The person who feels no sound sleep when getting up in the morning was 24.2% in Japan (Japanese Health and Welfare Trend Survey, 2003). Comfortable sleep is one of the important

problems in the health care. The purpose of this study was to clarify the sleep and mental problem for health care of comprehensive community sports club members in Japan northern area. Subject & Method: Subjects in this study were 81 middle and elderly people with a mean age of  $61.0 \pm 7.3$  (SD). They were members of comprehensive community sport club, which is called SPOR club, participated in a fitness class. Life-style, including sleep habits, and psychological measurements were taken. The life-style measurements were smoking, exercise and sleep habits. Sleep habits were measured by time of getting to bed, sleep-onset latency, time of getting up, sleep duration, nap habits, subjective symptom of lack of sleep and Japanese version of Pittsburgh Sleep Quality Index (PSQI-J). The psychological measurement used a 30-item General Health Questionnaire (GHQ30). Statistical analysis used SPSS. Result: Subjects who have no habit of smoking were 97.5%. Duration of exercise habit was  $64.6 \pm 73.1$  (SD) months. In sleep duration, classification of over 6 hours and under 7 hours was significantly longer than other classification. Total point of PSQI-J was  $8.9 \pm 4.1$  (SD) and total point of GHQ30 was  $GHQ30\ 3.5 \pm 3.9$  (SD). There was a significantly positive correlation between PSQI-J and GHQ30. In each factor on the GHQ30, the ratio of the persons with a high score (3-5 point) of sleep disturbance was about 25 percent. It was higher than in the other factors of GHQ30. Discussion: From these results, it was suggested that there were the relationships with exercise habit, sleep habits and a level of mental health. According to results of PSQI-J and GHQ30, there were a relationships between sleep quality, sleep-onset latency, sleep disturbances, use of sleep medication, daytime dysfunction and mental health. From the ratio of the persons with the highest scores in the factor of the GHQ30, it was suggested that one in four persons experienced a sleeping disorder. It was supposed that sleep habit changed better with duration of exercise habit. Continuous measurement is necessary to assess the change of these indexes. Acknowledgments: This study was financially supported by a grant from Hokusho University Northern Regions Lifelong Sports Research Center (SPOR). References: King AC et al., (2008) J. Gerontology, 63, 9, 997-1004 Weinstein et al., (2007) Med. Sci. Sports Exerc, 39, 4, 735-741

### PREVENTION MEASURES FOR HYPOTHERMIA USING A RESCUE SHEET DURING A SHORT TIME STAY IN A SNOW HOLE

WOORAM, B., ONODERA, S.1, AKIRA, Y.2, TERUMASA, T., YUKA, N., YUSUKE, T., TATSUYA, S., KEITA, A.3, KAZUKI, N.4, SEKI, K.5

KAWASAKI UNIVERSITY OF MEDICAL WELFARE

1:KUMW(Okayama, Japan), 2:KUPH(Kagawa, Japan), 3:GSKUMW(Okayama, Japan), 4:HIT(Hiroshima, Japan), 5:UMDS(Kobe, Hyogo) Introduction Humans have typical responses for exposure to coldness. Hypothermia is a serious medical condition caused by extreme cold. Prompt action is needed in the case of exposure to coldness. Therefore, the aim of this study was to examine the usefulness of prevention measures for hypothermia using a rescue sheet during a short time stay in a snow hole. Methods Six healthy young men participated in this study. Each of them gave informed consent. Each one put on a rescue sheet as if in an emergency, and stayed for one hour in the snow hole; one subject per hole. Heart rate (LRR-3: Nihonkohden), rectal temperature (YSI Precision 4000 A Thermometer), the scale of subjective thermal sensation and the activity of the parasympathetic nervous system (MemCalc/Tarawa) were measured during each stay in the snow hole. Two snow holes were prepared: A: 105cm height, 110cm width and 110cm interior, B: 116cm height, 109cm width and 116cm interior. Temperature in the snow holes were  $A: 3.7 \pm 0.7$  and  $B: 3.3 \pm 0.8$  degrees centigrade. Results The starting and closing heart rates for the experiment were  $70 \pm 7.4$  bpm and  $75 \pm 9.0$  bpm respectively. The differences in starting and closing rectal temperatures were  $-0.03$  degrees centigrade. Starting and closing LogHF were  $2.7 \pm 0.8$  and  $2.6 \pm 0.9$ . The starting and closing scores of subjective thermal sensations were  $1.3 \pm 0.8$  and  $3.3 \pm 0.9$  respectively. There were statistically no changes in each measurement of heart rate, score of subjective thermal sensation, activity of the parasympathetic nervous system and rectal temperature (ANOVA). Discussion Heart rate when exposed to cold temperatures, significantly decreases with time passage. According to a previous study, the decreasing tendency of the heart rate is controlled by measures against cold. The result of this study suggests that the rescue sheet controlled this decreasing tendency of the heart rate. Spectral analysis of cardiovascular signals, such as the heart rate R-R interval, systolic and diastolic blood pressure, provides useful indices of short and long-term changes in neural autonomic control. The RR HF component reflects mostly vagal modulation (Pagani et al., 1986). According to the previous study, a score of subjective thermal sensation was significantly increased, and the activity of the parasympathetic nervous system was significantly decreased during a stay in a snow hole (Onodera et al. 2009). The increased tendency to the score of the subjective thermal sensation is controlled by the activity of the parasympathetic nervous system. Consequently, it was not conceivable that there appeared to be typical responses. These data suggest that using the rescue sheet (or tarpaulin) for an emergency is effective to inhibit a decrease of the physiological indexes during a short stay in a snow hole. #### ANTHROPOMETRIC AND PHYSIOLOGICAL CHARACTERISTICS OF CLUB AND VARSITY LEVEL HURLING PLAYERS.

KIERAN, C., QUINN, C., DORAN, D.A.

ITT DUBLIN

ANTHROPOMETRIC AND PHYSIOLOGICAL CHARACTERISTICS OF CLUB AND VARSITY LEVEL HURLING PLAYERS. Collins, K. 1, Quinn. C. 2, Doran, D.A. 2. 1: ITTD (Dublin, Ireland), 2: LJMU (Liverpool, England) Introduction An understanding of position-specific demands within hurling may be useful in training protocol development and performance monitoring. The aim of this study was to examine the anthropometric and physiological characteristics of club and varsity level hurling players in relation to playing position. Methods Twenty-nine male competitive hurlers (age  $21 \pm 2.07$  yrs; height  $179.3 \pm 0.6$  cm and body mass  $80.5 \pm 9.4$  kg) underwent anthropometric and physiological assessment at the midpoint of the competitive season. The anthropometric variables of height and body mass were determined. Percentage body fat (BF%) and lean muscle mass (LM) were assessed by Dual X-ray absorptiometry (DXA) (Hologic QDR, USA). Physiological characteristics of countermovement jump (CMJ), linear sprint speed over 10, and 20 m; repeated 35 m sprint performance and fatigue index (RAST), agility (AGT) and estimated  $VO_{2max}$  were determined. Players were classified as defenders (DF), midfielders (MF), or forwards (FW) for the purpose of positional data analysis. Results Significant positional differences were evident in height and body mass ( $P < 0.01$ ) but not in BF% or LM ( $P > 0.05$ ). Generally, MF were taller, heavier, leaner and more muscular ( $186.4 \pm 8.4$  cm;  $86.9 \pm 4.6$  kg;  $14.6 \pm 1.0$  %;  $68.6 \pm 2.2$  kg) than DF ( $186.4 \pm 8.4$  cm;  $86.8 \pm 1.3$  kg;  $20.3 \pm 5.7$  %;  $60.3 \pm 6.0$  kg) or FW ( $177.2 \pm 8.4$  cm;  $76.2 \pm 4.0$  kg;  $18.6 \pm 3.8$  %;  $58.2 \pm 6.8$  kg). No positional differences were detected for CMJ height ( $P > 0.05$ ), with FW ( $50.0 \pm 7.5$  cm) and MF ( $49.1 \pm 7.1$  cm)

performance exceeding that of the DF ( $44.8 \pm 2.3$  cm). No positional differences in 10 and 20 m linear sprints were detected ( $P > 0.05$ ). Forwards were faster ( $1.9 \pm 0.1$ s;  $3.1 \pm 0.2$ s) than DF ( $2.0 \pm 0.4$ s;  $3.4 \pm 0.5$ s) with MF slowest ( $2.1 \pm 0.3$ s;  $3.5 \pm 0.1$ s). Fatigue index during RAST performance was higher in FW ( $26.6 \pm 10.8\%$ ) relative to DF ( $18.0 \pm 9.3\%$ ) and MF ( $22.0 \pm 5.4\%$ ) ( $P > 0.05$ ). Agility was higher in MF relative to DF ( $6.9 \pm 0.2$ s vs.  $7.7 \pm 1.3$ s;  $P = 0.04$ ) but not FW ( $7.1 \pm 0.4$ s;  $P > 0.05$ ). Estimated  $\text{VO}_{2\text{max}}$  differed between positions ( $P = 0.047$ ). Midfielders exhibited significantly higher  $\text{VO}_{2\text{max}}$  ( $50.2 \pm 2.4$  mL·kg<sup>-1</sup>·min<sup>-1</sup>) than DF ( $44.4 \pm 8.5$  mL·kg<sup>-1</sup>·min<sup>-1</sup>) and FW ( $44.6 \pm 6.9$  mL·kg<sup>-1</sup>·min<sup>-1</sup>). No differences were noted between DF and FW ( $P > 0.05$ ). Discussion Positional differences in the anthropometric and physiological characteristics of club and varsity hurling players show little significant variance across playing positions. Despite the statistical homogeneity a physiological and anthropometric hierarchy is apparent. The general performance level across most parameter falls short of that apparent at higher levels of the game. Future research should consider if this positional homogeneity is characteristic of performer at a more elite level. References

## **EFFECT OF BODY HEIGHT DIFFERENCE ON THE BALL KICKING PERFORMANCES DURING ADOLESCENCE MALE SOCCER PLAYERS.**

TAKANORI, T., TSUNODA, N.

KOKUSHIKAN UNIVERSITY

**Introduction** The purpose of this study was to investigate the effect of body height difference on the ball kicking performances during adolescence male soccer players. **Methods** The study participants included 149 Japanese male soccer players aged from 12 to 15 years. The participants were classified into 2 factors on the basis of their chronological age (age difference) and average body height (body height difference: higher and lower to the average body height group). Body compositional parameters for body height (BH), body weight (BW) and fat free mass (FFM) of the whole body were measured using the body impedance analysis method. Muscle thickness of thigh anterior (MTA: including rectus femoris and vastus intermedius) was measured by Ultrasonography method (SSD-900, Aloka). Cross-sectional planes were imaged at 50% of femur length from trochanter major to lateral condyle of femur, starting at the trochanter major. The ball distance (BD) was measured by the tape measure. The ball velocity (BV) was measured using a Rader gun. By using a custom-made speed meter, we measured the maximal swing velocity of the lower limb (SV) while the players were kicking the ball. **Results** With respect to BH, FFM, BD, BV and SV, there were significantly differences from 12 to 15 years old. However, MTA was significantly increased from 14 to 15 years old. BH and FFM were significantly body height differences from 12 to 15 years old. But also, MTA was showed significantly body height difference in 13 years old. There were showed significantly body height differences from 12 to 13 years old in BD. With respect to BV, there was significantly body height difference from 13 to 15 years old. However, SV was showed significantly body height difference in only 13 years old. Moreover, in the relationship between FFM and BD, BV and SV, higher body height group plotted higher performances than lower body height group. **Discussion** Body height difference during adolescent was affected on development of ball kicking performances. Moreover, higher body height group showed heavier FFM than lower body height group. Therefore, it was considered that body height difference was affected to FFM (muscle volume) during adolescence. From these results, it was suggested that body height growth may be affected on ball kicking performances during adolescence. **Reference** Malina RM, Peña Reyes ME, Eisenmann JC, Horta L, Rodrigues J, Miller R. ## **REPRESENTATION OF FOOTBALL PLAYERS' TRAJECTORIES USING SURFACE MAPS.**

MOURA, F.A., SANTANA, J.E., BARROS, R.M.L., CUNHA, S.A.

CAMPINAS STATE UNIVERSITY

**Representation of football players' trajectories using surface maps.** Felipe Arruda Moura, Juliana Exel Santana, Ricardo Machado Leite de Barros and Sergio Augusto Cunha. Laboratory of Instrumentation for Biomechanics, University of Campinas, Campinas, Brazil. **Introduction** The development of automatic tracking systems has allowed analysing football players' physical, technical and tactical performances. However, there is a lack of studies related to analysis of players' trajectories as tactical information. Therefore, the aim of this study was to propose a representation of football players' trajectories using surface maps. **Methods** The 2D players' positions as function of time during a Brazilian First Division Championship match were obtained using DVideo software, by its specific interface developed to track football players (Figueroa et al., 2006a; Figueroa et al., 2006b). For the representation of each player trajectory, we created a 3D shaded surface (the surface maps). Thus, we divided the football field in small squares and then we quantified the total number of frames that the player stayed inside each square. This information was stored in a matrix F that was used as the high of the 3D surface, associated to the x and y coordinates of each square centre. Squares with greater high values were coloured red and the minor values were coloured blue. Finally, the colour shading of surface was interpolated across the square faces. **Results** The surface maps to each player trajectory were created, for the first and second halves. With these data, it is possible to analyse team organization on the field and how it changes from the first to second half. **Discussion** A previous study proposed a representation of players' positions where they touched the ball using Principal Components Analysis (Barros et al., 2006). According to the authors, this kind of representation, for all players in a same figure, can be associated to tactical organization of the team. On the other hand, the analysis proposed in the present study has the advantage of representing, during the entire match, the field positions where player frequented most, although it is not possible to visualise all team in a same figure. **Results** allowed concluding that surface maps are efficient in to provide additional tactical insights for coaches. **References** Barros, R. ## **CHANGES IN HOMOCYSTEINE AFTER AN OFFICIAL SOCCER MATCH IN PROFESSIONAL MALE SOCCER PLAYERS**

SOUGLIS, G.A.1, HATZIS, G.2, TRAVLOS, K.A.3, GELADAS, N.1, BEKRIS, E.1, SOTIROPOULOS, A.1

UNIVERSITY OF ATHENS

1: Department of Physical Education and Sports Science, National and Kapodistrian University of Athens, (Athens Greece). 2: Department of Medicine, National and Kapodistrian University of Athens, (Athens Greece 3: Department of Sports Organization and Management, University of Peloponnese, (Sparta - Laconias, Greece) **Introduction** Soccer is the most popular sport in the world and played by men,

women and children. It is one of the major types of exercise modifying significantly homeostasis of human body. However, it is still unclear whether a soccer game can modify the basal levels of inflammatory markers. The aim of this study was to examine changes caused by an official soccer match on inflammation markers, such as homocysteine (Hcy) in the plasma of professional male soccer players. **Methods** The study consisted of 22 professional male soccer players defining the experimental group ( $23.14 \pm 2.97$  yrs;  $180.91 \pm 6.12$  cm;  $75.96 \pm 5.77$  Kg;  $10.60 \pm 0.62\%$ ;  $12.59 \pm 2.89$  yrs; for age, height, body mass, % body fat, and training experience, respectively; mean  $\pm$  SD) and a control group of 20 participants with similar characteristics (age, weight, height, body mass fat). In both groups, blood was taken before the match, immediately after the match, as well as 24 and 48h after the match. **Results** Groups by Measures (2 x 4) ANOVA with repeated measures on the last factor for homocysteine ( $\mu\text{mol/l}$ ) showed statistical significant differences for Groups ( $F_{1,40} = 4.26$ ,  $p < 0.05$ ), Measures ( $F_{3,120} = 264.21$ ,  $p < 0.0001$ ), and Groups by Measures interaction ( $F_{3,120} = 264.21$ ,  $p < 0.0001$ ). Bonferroni post hoc analyses of the significant interaction indicated that soccer players had significantly lower concentration of homocysteine (a) before the game ( $M = 6.80 \pm 1.46$ ) compared to concentrations immediately ( $M = 8.06 \pm 1.67$ ), 24 hours ( $M = 12.86 \pm 2.75$ ) and 48 hours after the game ( $M = 7.76 \pm 1.74$ ), (b) immediately after the game compared to concentrations 24 hours after the game, and (c) significantly higher concentration of homocysteine immediately and 24 hours after the game compared to concentrations 48 hours after the game. The rest of paired comparisons did not reach statistical significance. Also, no statistically significance was observed among the 4 measurements of the control group. **Conclusions** Our results show that an official soccer match is a quite demanding type of exercise related with significant changes in plasma levels of inflammatory markers, such as homocysteine. These findings suggest that soccer players should enter a recovery period after a single soccer game in order to regain their homeostasis before exposing themselves to a new acute bout of exercise.

### INFLUENCE OF A SOCCER MATCH ON THE CARDIAC AUTONOMIC CONTROL OF REFEREES

BOULLOSA, D.A., TUIMIL, J.L., LEICHT, A.S.

UNIVERSIDADE CATÓLICA DE BRASÍLIA

The aim of this study was to: assess the impact of soccer refereeing on the cardiac autonomic control as determined by heart rate variability (HRV); and examine the potential relationships between HRV and cardiovascular stress (time spent at an exercise intensity relevant to maximum heart rate, HRmax) during matches. Sixteen referees of both sexes volunteered for this study and completed 24-hr beat-by-beat heart rate recordings during a match and a rest day. Compared to the rest day, referees exhibited significantly lower 24-hr HRV and parasympathetic modulations during the match day. Similarly, night-time (00:00-05:00) HRV was significantly lower on match day compared to the rest day indicating an impaired HRV after the match. Greater resting HRV was significantly associated with greater match time spent at an intensity  $>85\%$  HRmax during the match ( $p=0.524-0.728$ ,  $p<0.05$ ). The current results confirm that soccer referees exhibit significant physiological stress during matches that continues for at least 10 hours post-match (i.e. lower post-match HRV). Resting HRV may provide a simple and prognostic tool for the monitoring of soccer referees' cardiovascular function prior to, during, and following matches irrespective of fitness characteristics.

### RELIABILITY OF ANAEROBIC PERFORMANCE TESTS IN SOCCER

SEKULIC, Z., LEPIR, D., MARKOVIC, S., LUKIC, A., GERDIJAN, N.

FACULTY OF PHYSICAL EDUCATION AND SPORT

**RELIABILITY OF ANAEROBIC PERFORMANCE TESTS IN FOOTBALL** Sekulic, Z.I., Lepir, D.I., Markovic, S.I. 1: Faculty of physical education and sport (Banja Luka, Bosnia and Herzegovina) **Introduction** The aim of this study was to examine the reliability of measurement tests of anaerobic performance in sprint and jump ability in football. The main aim is to establish the reliability of tests of muscular power through the four tests commonly used in testing players. **Methods** Twenty-six senior players from the Premier League Bosnia & Herzegovina participated in this study. They performed three consecutive trials for the four tests of muscular power (5 and 10 meters sprint, squat jump and countermovement jump). Testing was conducted using the Globus Ergo Tester. Reliability of measurement is expressed by coefficient of variation (CV). **Results** Coefficient of variation was 3.42 % for 5 meter sprint test and 2.77 % for 10 meter sprint test. For the squat jump test CV was 10.58 %, and countermovement jump test CV was 10.40 %. **Discussion** Sprint tests have better reliability than the vertical jump tests. Players must be more familiar with the protocol for the reduction of variation found in repeated trials when conducting SJ and CMJ. **References** Carling, C.; Reilly, T.; Williams, A. M. (2009). Performance Assessment for Field Sports, 133 -170. Taylor & Francis Routledge Stølen, T., Chamari, K., Castagna, C., Wisløff, U. (2005). Sports Med 2005; 35 (6): 501-536.

### REPEATED SPRINT ABILITY AND SKILLS IN ADOLESCENT SOCCER PLAYERS

VALENTE-DOS-SANTOS, J.I., FIGUEIREDO, A.J.I., FRANCO, S.I., HUIJGEN, B.C.H.2, ELFERINK-GEMSER, M.T.2, MALINA, R.M.3, COELHO-E-SILVA, M.J.1

1 FCDEF (UNIVERSITY OF COIMBRA, PORTUGAL), 2 UMCG (UNIVERSITY OF GRONINGEN, THE NETHERLANDS), 3 FACSM (FELLOW OF THE AMERICAN COLLEGE OF SPORTS MEDICINE)

**INTRODUCTION** The development of sprinting and dribbling were investigated among youth soccer players aged 12–19 (Huijgen et al., 2010). Dribbling appeared to improve further after late adolescence, while sprinting after that age hardly improved. The present study identified the predictors of repeated sprint ability and skills in adolescent soccer players. **METHODS** The sample included 159 Portuguese players aged 11–12 ( $n=75$ ) and 13–14 ( $n=68$ ) years. Measurements included chronological age (CA), skeletal age (SA: Roche et al., 1988), pubic hair (PH: Tanner, 1962), anthropometry (height, sitting height, weight and sum of four skinfolds), repeated sprint ability (RSA: 7x35-m sprints with a 25-s recovery interval), composed soccer skill score derived from four tests (Figueiredo et al., 2009), and experience. Multiple linear regression analysis was used to examine the independent effects of age, maturity, body size and proportions, adiposity and experience on RSA, skills and the composite skill scores. **RESULTS** Explained variances differed among the functional capacity (best sprint: 27–48%) and skills ( $<25\%$ ). Training experience and body size were the predictors of best sprint in both groups. Age and adiposity were primary predictors in players aged 11–12 years, while experience and a proportionally longer trunk appeared among predictors in players aged 13–14 years. Stage of PH did not contribute to explained variances in any indicators of functional capacity and soccer skill in both age groups. **DISCUSSION** Adolescent players somewhat delayed in SA for CA (lower SACA ratio) tended to have a higher soccer skill composite score. Experience in soccer and CA had a positive influence while adiposity in younger players and body weight in older players had a negative influence on dribbling. Future studies should include skeletal age as the best indicator of biological maturation. Additional research is needed to examine longitudinal changes of functional and skill scores (using multilevel) separately for early puber-

tal players contrasting in biological maturation at the baseline. ACKNOWLEDGMENTS Partially supported by FCT (SFRH/BD/64648/2009; PTDC/DES/2011) REFERENCES Figueiredo AJ, et al. ## STRENGTH, SPEED AND JUMPING ABILITIES OF TALENTED MALE AND FEMALE HANDBALL PLAYERS

INGEBRIGTSEN, J., RODAHL, S.

UNIVERSITY OF NORDLAND

**Introduction** In team handball a variety of skills and fitness components is required to perform at a top level, and the sport is hallmarked by intermittent high speed and explosive activities, interspersed by low intensity activities (Ziv and Lidor 2009). Therefore, this study first aimed to examine strength, speed and jumping abilities in talented youth handball players, and secondly to compare Under-18 and Under-16 players in the selected parameters. **Methods** Male (n=29) and female (n=29) youth handball players chosen by the Norwegian Handball Federation (NHF) were tested in strength (squat and bench press), speed (10m, 30m and repeated sprint ability of 6\*30m) and jumping abilities (CMJ and SJ), and also had their anthropometrics measured. To reveal possible differences in mean between the U-18 and U-16 within both male and female handball players we applied independent t-tests. Differences were considered significant at  $p < 0.05$  and results are presently expressed as means  $\pm$  standard deviations (SD). **Results** No significant differences in anthropometry were observed between U18 and U16 in male or female players. Further, within male players we did not observe any between group differences ( $p \leq 0.05$ ) in any of the tested performance parameters. However, the U16 male (n=14) players on average perform slightly better in all tests, than the U18 (n=15) male players. Moreover, we did not find any significant ( $p \leq 0.05$ ) differences in test performances between U18 female players and U16 female players either. A few trends ( $p \leq 0.1$ ) were however observed. First, in both 10m sprint ( $2.04 \pm 0.10$  vs.  $2.11 \pm 0.10$  s) and 30m sprint ( $4.87 \pm 0.22$  vs.  $5.03 \pm 0.22$  time, a trend ( $p \leq 0.1$ ) towards female U18 (n=14) players running on average faster than female U16 (n=15) players were found. Secondly, findings indicated a trend ( $p \leq 0.1$ ) towards female U18 players jumping higher ( $25.80 \pm 4.27$  vs.  $23.25 \pm 3.42$  cm) in SJ than female U16 players. **Discussion** We examined anthropometry and strength, speed and jumping abilities in talented U18 and U16 male and female handball players. The hypothesis of taller and heavier U18 players, due to pubertal development and muscle growth, were not verified, as no anthropometric differences were revealed between age classes in any of the sexes. Further, due to the assumption that U18 players train more hours and harder, we expected U18 players to perform better in all tests than U16 players, but this were not observed either. However, within female players a trend towards U18 performing better than U16 was seen within 0-10m sprint, 0-30 sprint and SJ. As we don't know the contents of the current training plan for any of the players, findings cannot be further explained. **References** Ziv, G. and R. Lidor (2009). *Eur Journ Sport Sci*, 9(6): 375-386.

## SQUAT AND BALANCE ABILITY IN YOUNG FOOTBALL PLAYER

BONFANTI, L., CORTE, A., BOCCOLINI, G., ALBERTI, G.

UNIVERSITÀ DEGLI STUDI DI MILANO

**Introduction** Squat is one of the most important training exercises used to improve strength efficiency. This basic exercise needs muscular coordination, joints flexibility, stability and postural control (Krintz M et al., 2009). Therefore, balance ability could affect the correct exercise execution. Aim of this research is to check a factual correlation between a correct squat execution and balance ability in young amateur football players. **Methods** 42 male young amateur football players ( $16.3 \pm 1.3$ ) have been evaluated. Dynamic functional postural analysis of squat exercise, tested with simplified squat test (Alberti G., Milan, 1980), and balance ability (LPF), evaluated with Libra (Easytech, Prato, Italy), have been assessed. Subjects were split in groups based on both types of exercise performed: full (FS), deep (DS) and half squat (90°); and on factors limiting the performance: ankle (A) range of motion and lumbar (L) flexibility. LPF results of different groups were correlated together and analysed with ANOVA for repeated measures on SPSS v.15 software.  $P < 0.05$  was chosen as the significant rate. **Results and Discussion** Average values show no statistical diversity in balance ability between FS, DS and 90°, while best results present a significantly greater balance performance in DS than 90° ( $p < 0.01$ ). Finally, FS-L group best results show balance performances significantly higher than FS-A ( $p < 0.005$ ). **Conclusions** The study indicates that the best DS and FS exercise execution seems related to the balance ability improvements. FS executions also pointed out balance performances rising in subjects with greater ankle ROM and lumbar flexibility. **References** Kritz M., Cronin J., Hume P. ## PEAK POWER IN FULL SQUAT RELATED TO DECREASED KICK SPEED AFTER FATIGUE INDUCED BY REPEATED SPRINTS IN SOCCER PLAYERS

LÓPEZ SEGOVIA, M., PALAO, J.M., GONZÁLEZ-BADILLO, J.J.

FEDERACIÓN DE FÚTBOL DE LA REGIÓN DE MURCIA

**PEAK POWER IN FULL SQUAT RELATED TO DECREASED KICK SPEED AFTER FATIGUE INDUCED BY REPEATED SPRINTS IN SOCCER PLAYERS** López-Segovia, M.1, Palao, J.M.2, González-Badillo, J.J.3 1: Research Center of Murcia Soccer Federation (Murcia, Spain), 2: University of Murcia (Murcia, Spain), 3: University of Pablo de Olavide (Seville, Spain). **Introduction** Kick execution in soccer is influenced by the fatigue produced by the repeated sprints (RS) that are characteristic of the game. Various studies have demonstrated the effect of fatigue on kick speed (KS) (Amiri-Khorasani et al, 2010; Kellis et al, 2006). However, in the bibliography review done, no studies have been found that analyze the loss in kick speed due to RS in relation to the player's lower-body power. The objective of the present study was to assess the relationship between RS ability and KS in function of the lower-body power of the soccer player. **Methods** Eighteen field players from a soccer team from the Spanish Third Division were analyzed. The RS protocol consisted of executing 40m series (with photoelectric cells placed at 0m and 40m to register time) with 2' of recovery between series, until 3% of the speed from the best series of each player is lost. Before and after those sprints (pre-post RS), each player took two instep kicks with each leg after running approximately 3m, with a minute of recovery between each kick. The speed of the best kick with each leg was recorded (Stalker Sport radar) for posterior analysis. A week later, each player completed a progressive full squat test with loads (FSL) (López-Segovia et al, 2010). The maximum power generated in the concentric phase with 20, 30, 40, 50, and 60 kg was recorded as an indicator of the profile of FS20-60 power for each player.

For data analysis, Pearson correlation and t-test were used. The alpha level was set at  $p < 0.05$ . Results Significant reductions in the SK for the dominant (3.3%) and non-dominant legs (6.6%) ( $p \leq 0.001$  and  $p \leq 0.000$ , respectively) were found. A significant relationship was found between the percentage of kick speed loss with the non-dominant leg and peak power in the F520-60 ( $r = 0.517$ ,  $p \leq 0.05$ ). This relationship was not found for the dominant leg. Discussion The lesser speed loss found with the dominant leg could be due to the greater stability and/or inter- and intramuscular coordination. These data seem to corroborate the absence of relationship between power and the speed loss for the dominant leg. Future studies should assess the level of loss of RS under game-like conditions and which workout protocols help to reduce the levels of loss of RS brought about by RS ability. #### STRENGTH TRAINING ELEVATES HSP27, HSP70 AND ACRYSTALLIN LEVELS IN MUSCULI VASTU LATERALIS AND TRAPEZIUS

HANSEN, K.E., PAULSEN, G., RØNNESTAD, B.R., KVAMME, N.H., UGELSTAD, I., KADI, F., RAASTAD, T.

NORWEGIAN SCHOOL OF SCIENCES

Introduction: Increased levels of Heat Shock Proteins (HSPs) have been found both after single bouts of high-force and endurance exercises, as well as after short periods of training. In this study we aimed at investigating changes in the HSPs levels after 2 (6 sessions) and 11 weeks of strength training. Methods: Fifteen young men ( $27 \pm 6$  yr,  $182 \pm 8$  cm and  $82 \pm 13$ ) were recruited and randomized to training either three sets in lower-body exercises and one set in upper-body exercises (3L-1UB), or one set in lower-body exercises and three sets in upper-body exercises (1L-3UB). Biopsies were obtained from m. vastus lateralis and m. trapezius before, during (after 2 weeks) and after 11 weeks of strength training (3 bouts per week). The biopsies were analyzed for HSP27, HSP70 and  $\alpha$ crystallin levels in the cytosolic and the cytoskeletal compartments. Results: For all subjects combined, a HSP response was observed as the cytosolic levels of HSP27 ( $186 \pm 69\%$ ) HSP70 ( $146 \pm 51\%$ ) and  $\alpha$ crystallin ( $184 \pm 82\%$ ) increased in vastus lateralis after 11 weeks of training. In trapezius the only observed increase was for HSP27 in the cytosolic fraction after 2 weeks of training ( $149 \pm 59\%$ ). However, trapezius contained higher levels of HSP70 and  $\alpha$ crystallin than vastus lateralis at baseline. HSP27 was measured in both the cytosolic and cytoskeletal cellular compartment, but changes were merely found in the cytosolic compartment. We found no evidence for an effect of training volume (1 vs. 3 sets) on the HSP response. Discussion: Without effect of training volume, strength training resulted in elevated levels of HSP27, HSP70 and  $\alpha$ crystallin in vastus lateralis. In trapezius, which contained higher levels of HSP70 and  $\alpha$ crystallin than vastus lateralis at baseline, only the HSP27 levels were increased (after 2 weeks) with training. #### A PRELIMINARY STUDY OF THE IMPACT OF EXERCISE ON PLASMA MUSCLE SPECIFIC MIRNAS

GOMES, C.P.C., FARIAS, L.R., PEREIRA, R.W.

CATHOLIC UNIVERSITY OF BRASÍLIA

A PRELIMINARY STUDY OF THE IMPACT OF EXERCISE ON PLASMA MUSCLE SPECIFIC MIRNAS Gomes, C.P.C1, Farias, L.R.2, Pereira, R.W.1 1: UCB (Brasília, Brazil), 2: UnB (Brasília, Brazil) Introduction There is much to learn about the muscular molecular adaptations to exercise and increasing evidence points to the importance of miRNAs in such processes. Since muscle specific miRNAs (myomiRs), have been vastly studied in skeletal muscle tissue but not as circulating miRNAs, here we investigated them in plasma. The main goal of this pilot experiment was to identify the levels of three myomiRs in plasma of high aerobically adapted individuals and whether their expression was significantly altered due to training. Methods Plasma was obtained from two high aerobically adapted individuals at rest and immediately after running. The miRNAs were isolated and then quantified in triplicates by real-time PCR using TaqMan miRNA Assays to miR-1, -133a and -206, and RNU48 as endogenous control. The relative changes in expression were calculated using the delta delta Ct method, where the mean delta Ct of each group was used for comparison. Statistical t-test was run for all data and results were considered significant at  $P < 0.05$ . Results miR-1, -133a and -206 on high aerobically adapted individuals were significantly higher after running compared to the levels at rest, where the increase was of 2, 2.68 and 5.63 times respectively ( $P < 0.02$ ). Discussion Since research on circulating miRNAs has focused in disease, it is unknown how exercise training changes myomiR expression. Two different studies, Nielsen et al (2010) and McCarthy and Esser (2010), showed a decrease in miR-1 and -133a levels in muscle biopsies after aerobic training. However the latter also observed an increase in the levels of the corresponding primary-miRNAs, including pri-miR-206. Meanwhile, Laterza et al (2009) reported an increase of the circulating muscle specific miR-133a after chemically induced muscle tissue injury in mice. In our findings, miR-133a was increased 168% after exercise, which might indicate muscle injury. We are aware of the limitations of our work regarding the number of subjects and the necessary aerobic parameters. Nevertheless, this was a first attempt to verify if it was relevant pursuing studies with myomiRs in plasma. Indeed, our results raise several questions including a very relevant one: is there any biological relevance of the increase of these myomiRs in plasma after exercise? #### LIVER NESFATIN GENE EXPRESSION AND ITS CONCENTRATION RESPONSES TO AN ENDURANCE TRAINING IN MALE RAT

GHANBARI-NIAKI, A., HOSSEINPOUR, F., FATHI, R.

UNIVERSITY OF MAZANDARAN

LIVER NESFATIN GENE EXPRESSION AND ITS CONCENTRATION RESPONSES TO AN ENDURANCE TRAINING IN MALE RAT Ghanbari-Niaki, A.1, Hosseinpour, F.1, Fathi, R.1 1: FPESS (Mazandaran, Iran) Introduction Nesfatin-1 is a novel anorexigenic protein that derived from Nucleo-

bindin-2 (NUCB2) gene (Oh et al., 2006; Goebel et al., 2009), expressed in adipose tissue and also is found in plasma (Li et al., 2010; Shimizu et al., 2008). The purpose of this study was to examine the effect of an eight week endurance training regimen on nesfatin gene expression and concentration in the male rat liver. Methods Eleven adult wistar male rats were used. Animals were randomly divided into Training (ES, n=6) and control (CS, n=5) groups. Training group was exercised on a motor-driven treadmill at 0% grade, 60 min, 5 days/week for 8 weeks (Katsuhiko and Jian, 2008), and 50-55%vo2max (Brooks and White, 1978). Excised liver samples were frozen in liquid nitrogen for determination of nesfatin-1 mRNA and liver concentration by RT-PCR & ELISA, respectively. Results Although liver nesfatin mRNA expression and its concentration were increased, changes were not significant. Also liver glycogen concentration was significantly higher in trained rats compared to control rats. Discussion The results of this research show for the first time that nesfatin-1 expressed in the liver and that it responded to endurance training. Insignificant variations of nesfatin-1 expression and concentration in liver might be attributed to the role of its in energy balance. ### **SIRNA-INDUCED SILENCING OF HYPOXIA-INDUCIBLE FACTOR 3A INCREASE OF EXERCISE ENDURANCE IN RATS**

DROZDOVSKA, S., GAVENASKAS, B., DREVITSKA, T., DOSENKO, V.

*NATIONAL UNIVERSITY OF PHYSICAL EDUCATION AND SPORT OF UKRAINE*

siRNA-INDUCED SILENCING OF HYPOXIA-INDUCIBLE FACTOR 3A (HIF3A) INCREASE OF EXERCISE ENDURANCE IN RATS Drozdovska S.1, Gavenauskas B.2, Drevitska T.2, Dosenko V.2 1: NUPESU (Kiev, Ukraine), 2: BIPH (Kiev, Ukraine) Introduction Exercise endurance depends on adequate adaptation of an organism to exercise-induced hypoxia. One of the crucial factors in this process is hypoxia-inducible factor that regulates transcription of many target genes encoding proteins that are involved in molecular adaptation to hypoxia (Mason S. et al., 2004; Lundby C. et al., 2009). The new data about antagonistic effects of different isoforms of HIF has been obtained recently – some splice variants of HIF3A can prevent transcription of target genes by HIF1A and HIF2A (Hara S. et al., 2001; Murphy B.J., 2004; Maynard M. et al., 2005). The aim of this study is to research exercise endurance of rats after knockdown of HIF3A using of siRNA. Methods The research was carried out on Fisher male rats (n=14). After a five-week swimming course with weight (O<sub>2</sub> consumption was on the level of 70-75% of peak intake) animals were injected into a tail vein with siRNA in dose of (80x1000) ng. In a week there was a second injection in the same quantity. The functional swimming test on exercise endurance was carried out before the first and second injections and 3 days after them. The effectiveness of RNA-interfering was estimated using Real-time PCR in muscles with preference of slow-twitch fibers (m. gastrocnemius) and fast-twitch fibers (m. soleus). Results Performing time of swimming test by HIF3A-knockdown rats after first and second injection of siRNA was 33% higher compared to control rats (injection of scrambled siRNA). Level of HIF3A mRNA expression was 2,6 fold (P<0.05) lower in m. gastrocnemius and 1.65 fold (P<0.05) in m. soleus compared to control. Discussion Obtained data indicate beneficial effect of HIF3A silencing on exercise endurance in rats and also proved previous results concerning negative effect of HIF3A in adaptation to hypoxia. siRNA-induced knockdown of this gene can be used for further researching of ways of exercise endurance increase and treatment of hypoxic conditions. ### **COLLAGEN V EXPRESSION IN CAPSULE OF ATHLETIC POPULATION UNDERGOING OPEN SHOULDER STABILIZATION**

AKHTAR, M.A., INGMAN, T.G., ROBINSON, C.M., KEATING, J.F., MUIR, A.Y., SIMPSON, H., SALTER, D.

*UNIVERSITY OF EDINBURGH*

Introduction: Shoulder dislocations are often caused by trauma, but predisposing intrinsic factors might also influence the risk. Collagen type V is widely distributed in tissues and helps regulate the diameters of fibrils of the abundant collagen type I. Mutations in its genes have been identified which can result in connective tissue fragility, particularly in skin and joints. The aim of this study was to assess if there is a correlation in the distribution of collagen V in capsule and Beighton score. Methods: Localization of Collagen V was studied by immunohistochemical staining of paraffin embedded sections of capsule from patients attending for open shoulder stabilization between Nov 2008 and July 2009. Grading of the stain was done on a 0-4 scale (0=no staining and 4=strong staining >50% of the slide) by three observers. Clinical examination was used to assess generalized ligament laxity using the Beighton score. Laxity is scored on a 0-9 scale. Scores of 4 or above are indicative of generalized ligament laxity. Results: 15 patients were studied undergoing open shoulder stabilization for recurrent instability. The mean age of patients was 24 years with a range from 16-31 years. 14 patients were male and 1 female. Most common sport played was rugby in 7 patients (47%) and football in 5 patients (33%). The average Beighton score for these patients was 2.4 with a range from 0-8. 4 patients (27%) had a Beighton score of 4 or above indicating generalized ligament laxity. Synovial surface of the capsule, blood vessels and extracellular matrix stained positive to varying degrees for collagen V. There was no correlation between Beighton score and collagen V expressions in the extracellular matrix of the capsule. Discussion: We studied the expression and distribution of Collagen V in capsule of patients undergoing open shoulder stabilization and found no correlation with Beighton score. This study highlights the complex role of different genes involving Collagen V which are responsible for extracellular matrix organization and strength of the shoulder capsule.

### **SMALL LEUCINE RICH PROTEOGLYCAN EXPRESSION IN SHOULDER CAPSULES OF ATHLETIC POPULATION UNDERGOING SHOULDER STABILIZATION**

AKHTAR, M.A., INGMAN, T.G., ROBINSON, C.M., KEATING, J.F., MUIR, A.Y., SIMPSON, H., SALTER, D.

*UNIVERSITY OF EDINBURGH*

Introduction: Shoulder dislocations are often caused by trauma, but predisposing intrinsic factors might also influence the risk. Decorin and biglycan are members of the SLRP's family which are important constituents of interstitial extracellular matrices (ECM) and play important roles in the regulation of collagen fibrillogenesis. Their deficiency could influence wound healing and integrity of skin and muscle. The aim of this study was to assess if there is a correlation in the distributions of SLRP's in capsule and Beighton score. Methods: Localiza-

tion of decorin and biglycan was studied by immunohistochemical staining of paraffin embedded sections of shoulder capsule from patients attending for shoulder stabilization between Nov 2008 and July 2009. Grading of the stain was done on a 0-4 scale (0=no staining and 4=strong staining >50% of the slide) by three observers. Clinical examination was used to assess ligament laxity using the Beighton score. Laxity is scored on a 0-9 scale. Scores of 4 or above are indicative of generalized ligament laxity. Results: 15 patients were studied undergoing open shoulder stabilization for recurrent instability. The mean age of patients was 24 years with a range from 16-31 years. 14 patients were male and 1 female. Most common sport played was rugby in 7 patients (47%) and football in 5 patients (33%). The average Beighton score for these patients was 2.4 with a range from 0-8. 4 patients (27%) had a Beighton score of 4 or above indicating generalized ligament laxity. Synovial surface of the capsule, blood vessels and skeletal muscles stained negative but ECM was positive to varying degrees for decorin. There was no correlation between Beighton score and Decorin expressions in extracellular matrix of the capsule. Synovial surface of the capsule, blood vessels and ECM stained positive to varying degrees for Biglycan. There was no correlation between Beighton score and Biglycan expressions in the extracellular matrix of the capsule. Conclusions: We studied the expression and distribution of SLRP's (Decorin and Biglycan) and found no correlation between the Beighton score and SLRP's distribution in the extracellular matrix of the shoulder capsule. This study highlights the complex role of different genes including the SLRP's which are responsible for extracellular matrix organization and strength of the shoulder capsule.

### **TGF- $\beta$ ISOFORMS INHIBIT IGF-1-INDUCED MIGRATION AND REGULATE TERMINAL DIFFERENTIATION IN A CELL-SPECIFIC MANNER**

SCHABORT, E.J.1, VAN DER MERWE, M.2, NIESLER, C.U.3

1:UNIVERSITY OF CAPE TOWN, SOUTH AFRICA; 2:UNIVERSITY OF STELLENBOSCH, SOUTH AFRICA; 3:UNIVERSITY OF KWAZULU-NATAL, SOUTH AFRICA

**Introduction** Following muscle injury, the damaged tissue and influx of inflammatory cells stimulate the secretion of growth factors and cytokines to initiate repair processes. This release of chemotactic signaling factors activates resident precursor cells and stimulates their mobilization and migration to the site of injury where regeneration can occur. In terminally differentiated adult skeletal myofibers, repair is carried out by a small population of stem cells called satellite cells, which are activated in response to disease or trauma, forming myoblasts which aids regenerative processes. Similarly, endogenous cardiac stem cells have also been identified, although they seem to have limited effect in functional repair (Collins and Russell 2009). Furthermore, although the transplantation of exogenous stem cells has shown promising results, consistent and functional cardiac repair has not been demonstrated. To be of greater therapeutic use, insight is required into the regulatory mechanism(s) of growth factors in the cytoplasmic milieu of progenitor cells which could optimize regeneration processes (Nadal-Ginard and Fuster, 2007). The three Transforming Growth Factor- $\beta$  (TGF- $\beta$ ) isoforms, and Insulin-like Growth Factor-1 (IGF-1) are among the known regulatory factors released following muscle damage. To determine the effect of these growth factors of muscle regeneration, we investigated the effect of TGF- $\beta$ 1, - $\beta$ 2, - $\beta$ 3 and IGF-1 on muscle progenitor cell migration and the effect of TGF- $\beta$  isoforms on myoblast fusion. **Methods** Recombinant active TGF- $\beta$ 1, - $\beta$ 2, - $\beta$ 3 (5 ng/ml) and IGF-1 (10 ng/ml) were used to determine their effect on C2C12 skeletal muscle satellite cell and P19 embryonal carcinoma cell differentiation and migration. C2C12 myoblast fusion, and P19 embryoid body formation and terminal differentiation were assessed following 72 hr TGF- $\beta$  treatment, whereas the effect of TGF- $\beta$  isoforms and IGF-1 on migration was determined following 7 hr incubation. **Results** Our results showed that TGF- $\beta$  decreases C2C12 myoblast fusion in an isoform-independent manner. In the P19 cell lineage, results demonstrate that TGF- $\beta$ 1 specifically and significantly increased P19 embryoid body formation, but not expression of connexin-43 or myosin heavy chain. IGF-1 significantly increased cell migration compared to TGF- $\beta$  isoforms, which, on their own, had no significant effect on the mobilization of either C2C12 or P19 cells. **Discussion** These results emphasize the importance of evaluating progenitor cell migration and fusion in context of the cellular and cytokine environment. A greater understanding of stem and progenitor cell activation, signaling and involvement in growth and repair, as well as the profile of growth factor expression during these processes, is essential in establishing more effective cell-based therapies. **References** Nadal-Ginard B, Fuster V. (2007) Myocardial cell therapy at the crossroads. *Nat Clin Pract Cardiovasc Med* 4(1):1. Collins JM, Russell B. (2009) Stem cell therapy for cardiac repair. *J Cardiovasc Nurs* 24: 93-97.

### **EFFECT OF ECCENTRIC EXERCISE VELOCITY ON MYOSTATIN AND FOLLISTATIN GENE EXPRESSION IN HUMAN SKELETAL MUSCLE**

ROSCHER, H.1, TRICOLI, V.1, UGRINOWITSCH, C.1, NEVES JR, M.T.1, AOKI, M.S.2

1 SCHOOL OF PHYSICAL EDUCATION AND SPORT, UNIVERSITY OF SÃO PAULO; 2 SCHOOL OF ARTS, SCIENCES AND HUMANITIES, UNIVERSITY OF SÃO PAULO

**Introduction** It has been suggested that eccentric exercise (EE) velocity seems to affect the magnitude of muscle mass increment. However, intracellular mechanisms that regulate acute increments in protein synthesis after each training session, which eventually lead to muscle hypertrophy, after fast EE training remains to be elucidated. Growth and differentiation factor-8 (GDF), also known as Myostatin (MSTN), is a transforming growth factor- $\beta$  family member that acts as an inhibitor of skeletal muscle hypertrophy. MSTN-deficiency has been associated to significant increases in muscle mass. MSTN activity is regulated by a protein known as Follistatin (FLST). FLST over-expression has been shown to promote muscle hypertrophy. Since EE produces muscle hypertrophy, it is reasonable to assume that this kind of physical training will induce down-regulation of MSTN signaling. The aim of this study was to compare the effect of fast and slow EE on MSTN and FLST gene expression. **Methods** Twenty four healthy male were randomly assigned to either a slow (20°s<sup>-1</sup>, n= 8) or fast (210°s<sup>-1</sup>, n=8) eccentric group. The acute exercise bout consisted of 5 sets of 8 reps of EE knee extensions (0 to 90°) at either slow or fast velocity on the isokinetic dynamometer, interspersed by 3 min rest interval. Peak torque, work, and impulse were calculated for each repetition throughout the sets of eccentric exercise. Muscle biopsy samples were taken before, immediately, and 2 h after the exercise bout. MSTN, FLST, follistatin related protein 3 (FLL-3) and GASP-1 gene expression were quantified by real time PCR. **Results** There were no differences in peak torque values between sets and velocities (p>0.05). Similarly, total work was similar between velocities (p>0.05). On the other hand, the total impulse and the impulse per set (main velocity effect) were significantly higher for the slow EE group (p<0.05). No changes were observed for MSTN mRNA content (p>0.05). A main time effect was observed for FLST, FLL-3 and GASP-1 (pre vs. 2h; p<0.05). No differences were found at any time point between velocities. **Discussion** The findings of the present study indicated that a acute bout performing EE activates similar gene expression responses related to components of MSTN signaling pathway. However, despite the previous data available reporting greater muscle hypertrophy responses after higher velocity EE, no difference were observed between high and low velocity EE in this study. It is possible that other intracellular pathways might be activated in response to EE training protocol.

## VALIDATION OF ISOLATION AND CHARACTERISATION OF CARDIAC STEM CELLS FROM THE FOUR CHAMBERS OF THE MOUSE HEART

BARCLAY, M., GASKELL, R., SMITH, A., WARING D., NADAL-GINARD, B., TORELLA, D., ELLISON, G.

LIVERPOOL JOHN MOORES UNIVERSITY

**Introduction** c-kitpos CD45neg Cardiac Stem Cells (CSCs) are a small subpopulation of cells with stem cell properties and regenerative potential within the embryonic and adult heart. We have previously shown that CSCs become activated and differentiate into new myocardial cell following exercise training, contributing to improved cardiac functional adaptation. Here, we show that CSCs are present in all four chambers of the adult heart and show similar phenotypic and functional characteristics. Furthermore, they can be routinely and efficiently isolated using several methods. **Methods** Whole mouse hearts from 6-week male C57BL6 mice (n=18) were dissected into the 4 chambers (right and left ventricle, right and left atrium). Small cardiac cells were isolated from each chamber using three different techniques: Enzymatic digestion, enzymatic digestion using GentleMACS® technology or explant culture technique. The percent number of c-kit positive (c-kitpos) CSCs were analysed for each chamber by flow cytometry. c-kitpos CSCs were enriched through magnetic activated cell sorting (MACS, Miltenyi) and characterised for chamber-specificity, surface markers by flow cytometry analysis, clonogenicity, multipotency and self-renewal. **Results** The efficiency of c-kitpos CSC isolation from each chamber using the 3 isolation techniques was similar, with ranges from 4 to 8% of the small cell population. Thus far, c-kitpos CSCs have been successfully enriched and lines cultured for the left atria (LA) and right ventricle (RV). These CSC lines are clonogenic (19±4%) and self-renewing. For two LA and two RV CSC lines at passage 5, flow cytometry analysis revealed maintenance of positivity for stem cell markers, c-kit and Sca-1, and negativity for CD45 (haematopoietic) and CD34 (endothelial). qRT-PCR analysis of the CSC clonal cell lines from the different chambers revealed expression of the multipotency genes. **Conclusion** c-kitpos CSCs are present in all 4 chambers of the adult mouse heart and can be successfully identified and routinely isolated using either enzymatic digestion or explant culture. c-kitpos CSCs enriched from the LA and RV express similar stem cell surface markers and multi-potency genes, indicative of an indistinct population of CSCs throughout the mouse heart.

## GROWTH FACTORS IN SKELETAL MUSCLE REGENERATION OF ELITE GRECO-ROMAN WRESTLERS

ZEMBRON-LACNY, A.1, KASPERSKA, A.1, ZUREK, P.1, HÜBNER-WOZNIAK, E.2

**Introduction** Skeletal muscles are able to regenerate after injury. This process is due to the activation of muscle precursor cells, called satellite cells, which proliferate and differentiate to form new myotubes. In this regeneration process, hydrogen peroxide, nitric oxide, cytokines and growth factors which come from the muscle and/or from motor nerve and inflammatory cells have been shown to play key roles. During recovery, most of these molecules have been released to circulation and could be useful in assessment of muscle regeneration in athletes (Kuang et al., 2008; Wilborn et al., 2009). The purpose of the study was to estimate the extracellular signals of satellite cells activity in elite Greco-Roman wrestlers in four training periods. **Methods** Twenty athletes, members of national team, were observed during two preparatory periods (January, December), pre-start period (April) and start period (June) differed in type and intensity exercise. In blood, concentrations of hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>), nitric oxide (NO), pro-inflammatory cytokines (IL-1 $\beta$  and TNF $\alpha$ ), hepatocyte growth factor (HGF), insulin-like growth factor (IGF-1), platelet-derived growth factor (PDGF-BB) and brain-derived neurotrophic factor (BDNF) were measured. Total creatine kinase (CK) activity was a marker of muscle damage. **Results** The levels of H<sub>2</sub>O<sub>2</sub>, TNF $\alpha$  and growth factors HGF, IGF-1, PDGF-BB and BDNF were significantly elevated during the second part of preparatory period and pre-start period where dominated the endurance exercises and technical training elements. NO increased during the mountain training in December. The changes in CK activity were not associated with growth factors levels and pro-inflammatory cytokines. Individual analysis of growth factors revealed that HGF, IGF-1 and PDGF-BB were most increased in top-athletes. **Discussion/Conclusion** We have concluded that wrestling training of high intensity has significant influence on growth factors accompanied by increase hydrogen peroxide and cytokine TNF $\alpha$ . However, the degree of release of HGF, IGF-1, PDGF-BB and BDNF and pro-inflammatory cytokines might be related to several factors that include the athlete's fitness level, exercise intensity, and exposure to environmental conditions. **References** Kuang S, Gillespie MA, Rudnicki MA. (2008). Cell Stem Cell, 2, 22-31. Wilborn CD, Taylor LW, Greenwood M, Kreider RB, Willoughby DS. (2009). J Strength Cond Res, 23, 2179-2186.

## OBSERVATION OF A WAVE-LIKE STRUCTURE IN ATROPHIED SKELETAL MOUSE MUSCLE USING SCANNING ELECTRON MICROSCOPY AND IMMUNOHISTOCHEMISTRY.

SAKAMOTO, M.1, KOGA, H.2, MURO, M.3, OKA, K.3

**Introduction** Skeletal muscle shows structural and functional changes and high plasticity, depending on stimulation levels. It has previously been reported that the soleus muscle immobilized in a shortened position forms a wave-like structure (Oka K et al. 2003). Reported structural changes associated with disuse muscle atrophy include a wavy contour and myofibrillar disruptions (Anzil AP et al. 1991). However, the relationship between the appearance of a wave-like structure and myofibrillar disruption is unclear. The purpose of the present study was to analyze the ultrastructural changes of muscle fibers in the wave-like structure using scanning electron microscopy (SEM). **The present experiment** was performed with a SEM method using paraffin sections that has been previously reported (Oka K et al. 2006). **Materials and Methods** The soleus muscles of 5-week-old female ICR mice were used in this study. These mice were divided into a control group and an immobilized group. In the immobilized group, the left hindlimb was immobilized at the ankle joint in maximum planter flexion. After 10 days of immobilization, the excised soleus muscle was fixed with acetone and embedded in paraffin in the usual manner. Longitudinal serial paraffin sections of 8 micrometer were made: 1 section was observed with SEM and 1 neighboring section in the series was stained with anti-collagen type IV antibody (a marker for endomysium). **Results** The muscle fiber showed a linear contour in the control group and myofibrils were visible. In muscle fibers of the immobilization group, wave-like structure was observed: it appeared as a groove, and was thought to be endomysium inserted into the cytoplasm of the muscle fiber. The wave-like structure was positive for anti collagen IV antibody. Based on these results, the structure which inserted into the cytoplasm and formed a groove was confirmed to be endomysium. Moreover, myofibrillar disruption was not observed at region of the wave-like structure. **Discussion** Atrophied muscle induced by tenotomy has been previously observed using SEM, and it has been reported that grooves appear in tenotomized muscle on the fiber surface (Abou Salem EA et al. 2001). The structural changes observed in the present study were speculated to be morphological changes similar to those that have been described as a groove in previous studies. Additionally, the myofibrils were

observed distinctly at a specific region of the wave-like structure, and it was suggested that myofibrillar disruption did not occur in the atrophied skeletal mouse muscle.

### CHANGES IN SALIVARY ANTIMICROBIAL PEPTIDES, IMMUNOGLOBULIN A AND CORTISOL AFTER PROLONGED STRENUOUS EXERCISE

USUI, T., YOSHIKAWA, T., ORITA, K., UEDA, S., KATSURA, Y., FUJIMOTO, S.

OSAKA CITY UNIVERSITY GRADUATE SCHOOL

The aim of the present study was to examine whether amount of oral antimicrobial components, human  $\beta$ -defensin-2 (HBD-2), cathelicidin (LL-37) and immunoglobulin A (IgA), might be affected by prolonged strenuous exercise. Ten young male volunteers either exercised on recumbent ergometer at 75 % VO<sub>2</sub> max for 60 min (exercise session) or sat quietly (resting session). Saliva samples were obtained at 60 min intervals during sessions for measurements of saliva antimicrobial components (HBD-2, LL-37 and IgA), saliva cortisol and osmolality. Saliva flow rate was decreased and saliva osmolality was increased during the 60-min exercise. Saliva HBD-2 and LL-37 concentrations and secretion rates were increased during and after the exercise, whereas saliva IgA concentration and secretion rates were decreased after the exercise. Saliva cortisol was increased during and after the exercise. The areas under the curve (AUC) of the time courses of saliva levels of HBD-2 and LL-37 were negatively correlated with those of cortisol levels in saliva. The present findings suggested a single bout of prolonged strenuous exercise caused a transient increase in the saliva HBD-2 and LL-37 levels. In addition, the transient rises in these antimicrobial peptide levels might be affected by increase in cortisol levels by the exercise.

### RELATIONSHIP BETWEEN CHANGE RATES OF SALIVARY CHROMOGRANIN A AND FATIGUE COMPLAINTS OF LANGUID BODY AND THIRST IN JUDO TRAINING AND LECTURE IN STUDENTS

SAKAMOTO, K.

HOGO COLLEGE OF MEDICINE

Relationship between change rates of salivary chromogranin A and fatigue complaints of languid body and thirst in judo training and lecture in students. Naomasa Sakamoto, Kunihiro Sakamoto Preventive Medicine, Hyogo College of Medicine, Japan Introduction: The relationships between the change rates of salivary chromogranin A (CgA) and physical fatigue complaints after judo training and lecture were examined. CgA was considered as one of the index of sympathetic system. In this study the fatigue complaints were considered the items of languid body and thirst feeding using enquete method authorized by the Japanese industrial hygienists association. The relationship was analyzed by multiple regression analyses using the dummy number for transition pattern of fatigue complaints. Methods: Subjects were eight healthy male students, nonsmoker, average age 24.75 years old and standard deviation 7.94 years old. Salivary collection and fatigue survey were down three times at the attend school, after the first lesson and after the second lesson. The fatigue complaints by judo and lecture lesson were examined using the descriptive enquete method of fatigue survey. The items of fatigue complaint category were considered the languid body as physical fatigue complaints and thirst feeling as neurosensitive fatigue complaints. CgA was measured by Yanaihara institute. The change rate of CgA by the load was measured as the base of data at the attending school. The transition patterns of fatigue complain were shown by dummy number as following; 100 of the incidence case, 010 of the continuous case and 001 of the disappearance case of fatigue complaint. Correlation coefficient and multiple regression analysis were down by Excel. Results: The change rates of CgA level were 0.715 of median value for judo and 0.603 of median value for lecture. The analysis was down using the all these data. Correlation coefficients( r ) between the change rate of CgA and the transition pattern of fatigue complaint were analyzed as following,  $r = -0.145$  for the disappearance of languid body and  $r = 0.291$  for the continuous of thirst feeling. The effects of the fatigue complaint on the change rate of CgA were analyzed by multiple regression method using dummy number of the transition pattern. The standard partial regression coefficients of the change rates of CgA to the fatigue complaint cases were  $-0.377$  for the disappearance case and  $0.476$  for the continuous thirst feeling case. Discussion. The disappearance of languid body complaint was showed to decrease tendency corresponding to increase the CgA level. It seemed that the languid body complaint might be disappeared by decrease of sympathetic condition. The continuous thirsty feeling was related to increase corresponding to CgA level. Thus, it seemed that the change rate of salivary CgA level was showed the relation between the sympathetic status and the thirst complaint.

### PP-PM21 Adaptive Physical Activity

#### OBJECTIVE QUANTIFICATION OF PHYSICAL ACTIVITY IN DOWN'S SYNDROME ADOLESCENTS. A PILOT STUDY

VIUDA-SERRANO, A., RUIZ-VICENTE, D., THEIRS RODRÍGUEZ, C.I., SALINERO, J.J., PÉREZ, B.

UNIVERSIDAD CAMILO JOSÉ CELA

OBJECTIVE QUANTIFICATION OF PHYSICAL ACTIVITY IN DOWN'S SYNDROME ADOLESCENTS. A PILOT STUDY Viuda-Serrano, A., Ruiz-Vicente, D., Theirs Rodríguez, C.I., Salinero, J.J., Pérez, B. Universidad Camilo José Cela INTRODUCTION Knowing the degree of physical activity in a population group becomes the first step to address sport promotion policies to encourage a healthy lifestyle that may have impact on better living conditions. Traditionally, we have used questionnaires and log books to ascertain the practice of physical activities and sports. Present times determine the use of technology, such as accelerometers, which have been shown to be a valid tool to objectively quantify physical activity levels in different populations. An accelerometer is an electronic device that collects accelerations produced by the body over a period of time. Through this instrument, we are able to know the fulfilment of official recommendations for physical activity and also the activity patterns followed by different groups. OBJECTIVE The aim of this study is to carry out a first approach to the objective quantification of physical activity in young people with Down syndrome in Spain. We also seek to know if they meet official recommendations of physical activity for health and patterns of physical activity. METHOD Five adolescents with Down syndrome aged  $17.8 \pm 1.2$  were analyzed for a week using GT3X tri-axial accelerometers. All recorded days were valid, except for two single days in one of the participants due to an illness. RESULTS Most of their physical activity was limited to sedentary or light activity. They performed about 30 minutes of moderate or vigorous activity, so did not meet physical activity recommendations. Subjects carried out an average over

8.000 steps a day, far away from the recommended 10.000 steps, although two of the participants reach more than 9.700 steps a day. Both in quantity and intensity, physical activity made on working days significantly exceeds that held on weekends. On average, half of physical activity (also in quantity and intensity) performed throughout the day is made within the school, which emphasizes the importance of school as a promoting or facilitating means for physical activity. CONCLUSION Accelerometers have been proved to be a valid tool to assess physical activity in special groups of population with specific characteristics, such as Down's syndrome adolescents. In the future, it would be interesting to extend the study sample, in order to draw meaningful conclusions about the physical practice of this collective. REFERENCES Fredriksen, P. M. et al. (2000). ## INTERDEPENDENCE OF PHYSICAL PERFORMANCE, FATIGUE AND DISABILITY IN FEMALE PATIENTS WITH RELAPSING REMITTING MULTIPLE SCLEROSIS

WONNEBERGER, M.1, WEBER, S.1, FROBÖSE, I.1, SCHMIDT, S.2

1: DSHS (COLOGNE), 2: AMBULANCE OF NEUROLOGY (BONN)

**Introduction** Fatigue is a frequent and often disabling symptom in patients with multiple sclerosis (MS) (Stuke et al., 2008) significantly affecting quality of life. In the present study we investigate the interdependence of physical performance, fatigue and disability in female patients with relapsing remitting multiple sclerosis (RR-MS). **Methods** Untrained female patients with RR-MS participated in this study (n=56, age 37 +/-8.3 years). The mean disability according to the expanded disability status scale (EDSS) was 1.9 +/-0.6. At the beginning of the examination all participants completed the fatigue severity scale questionnaire (FSS) (Krupp et al., 1989). Patients were then divided into a non-fatigue group (NF) with a FSS score value (FSS-sv) below 4.0 and a fatigue group (FG) with a FSS-sv of 4.0 and higher. Subsequently, all subjects completed a treadmill testing according to the modified Naughton protocol (Patterson et al., 1972). Gas exchange was measured continuously to determine the peak oxygen uptake during the treadmill test (VO<sub>2</sub>peak). Blood lactate concentration and heart rate were measured after each incremental. **Results** There were no significant differences between NF and FG with regard to the mean blood lactate concentration, heart rate and VO<sub>2</sub>peaks. The correlation between VO<sub>2</sub>peak and FSS-sv was also not significant (p>0.05). The EDSS correlated negatively with the VO<sub>2</sub>peak (p<0.001). **Discussion** We conclude that based on this cross-sectional approach, severity of fatigue in untrained MS patients had obviously no effect on physical performance. The significant correlation between EDSS and VO<sub>2</sub>peak can most likely be explained by the superior motoric skills in patients with lower EDSS scores. Other studies came to similar results (Motl RW & Goldman M, 2011). Further studies are needed to investigate the impact of specific physical exercise on fatigue and disability in patient with MS. **References** Krupp, L. B.; LaRocca, N. ## THE LEVEL OF CHANGES UNDER THE IMPACT OF WATER GAMES AND EXERCISES UPON MOTORIC STATUS OF THE CHILDREN WITH DOWN SYNDROME

TORLAKOVIC, A.1, RADJO, I.2, DAUTBASIC, S.2, GEC, M.

OLYMPIC SWIMMING POOL CENTER-SARAJEVO AND FACULTY OF SPORT AND PHYSICAL EDUCATION SARAJEVO

**BACKGROUND:** Many researches have shown that the development of motoric abilities with children with Down syndrome (DS) is significantly limited (Lauteslager, 1991). It's obvious that their motoric develops relatively slowly and it is accompanied by significantly reduced moving abilities (Jobling, 1994; Ulrich, 1992). The aim of this research was to establish the level of changes of motoric status under the impact of programme activities of water games and exercises of children with DS. **METHODS** The research has been conducted with the sample comprising of 12 children with DS, 8 male (n=8, mean age=9.7±3. yrs; mean height= 1.32±0.16m, mean weight= 41.9±15.5 kg) as well as 4 female examinees (n=4, mean age=9.1±3.6 yrs; mean height=1.29±0.13m; mean weight= 30.5±7.5 kg). The programme was carried out within the period of 12 weeks at the pool for non-swimmers training (average water temperature 28,6 C), twice a week per 60 minutes. Both prior and after the carried out programme, a testing of a part of motoric status was performed in order to establish the effects of the programme itself. For the analysis of initial and final testing, T-test for dependant samples has been used / marked differences are significant at p <, 0500) **RESULTS** The analyses of results for balance assessment „one leg standing“ (p=, 0012), the speed of alternative movements „hand tapping“ (p=, 0006), explosive force „ 20 meters sprint“ (p=,0000), coordination „slalom –ball rolling“ (p=,0034), flexibility „spread legs sitting bend“ (p=,0010) and coordination in water „ 12 meters shallow water running „ (p=,0001) show high level of statistic significance with all examinees. **CONCLUSIONS** Final results' testing shows statistically significant level of shanges in relation to the initial testing. Similar results were obtained by other authors proving that with the application of adequate physical exercise programme, motoric status is able to be improved, especially strength and balance at children with DS (Gupta, 2010). On the basis of this, it could be concluded that with appropriate impulse under the impact of various water games and exercises, significant improvement of the level of motoric status at children with DS is notable. **REFERENCES** Gupta, S., BK. ## THE ANALYSIS OF BODY BALANCE IN A PARALYMPIC SPRINTER: A CASE REPORT

BATTAGLIA, G.2, CARAMAZZA, G.1,2, BELLAFFIORE, M.1,2, BIANCO, A.1,2, PALMA, A.1,2

UNIVERSITY OF PALERMO

**Introduction** Trans-tibial amputation is responsible for biomechanical changes (i.e. absence of muscles, bones and joints) and modifications in both afferent and efferent projections. Because of these impairments, body balance is difficult to control and falls are a significant

problem for trans-tibial amputees (Curtze et al., 2010). The aim of our study was to evaluate whether specific exercises can improve body balance in a paralympic sprinter (category: T-44) after 7 weeks of training. Methods The athlete was a healthy and active female subject (age: 37 years; weight: 58.2 Kg; height: 161cm; BMI: 22.45) with an unilateral transtibial amputation to 1/3 of the right lower limb since the age of 2 years and 6 months. The athlete was tested during the 6th and 7th mesocycle of training macrocycle prior XIII Paralympics Games, Beijing 2008. During the experimentation we added in her sessions of training specific exercises to improve balance control systems such as walking along a line or on a wood support with open and closed eyes (OCE); swaying on proprioceptive footboard with OCE ect. Before and during the experimentation the typical week of training included 5 sessions of ~2 hours. Every session included a warm up pattern for about 20 minutes (min), a training period including about 20 min of specific pre-athletic exercises and 50 min of specific work, and a cool down step for 20 min. Balance control indicators, such as mean speed (MS), lateral-lateral mean speed (MS-x), anterior-posterior mean speed (MS-y), sway path (SP) and ellipse surface area (ESA) of the body mass center were analyzed by unipedal test on left foot (UTLF) with open or closed eyes using a stabilometric platform. All data were acquired before and after the experimentation. Results During unipedal test on left foot with open eyes all stabilometric parameters did not show any relevant modifications; while in UTLF with closed eyes MS, MS-x, SP and ESA decreased after 7 weeks of training. Discussion The exercises stressing balance control system appears to affect the postural stability of an athlete with trans-tibial amputation. We suppose that these kinds of exercises can improve the proprioceptive system of body balance control and preserve the subject from the fall risk (Viton et al., 2000). References Curtze C, Hof AL, Otten B, Postema K: Balance recovery after an evoked forward fall in unilateral transtibial amputees. *Gait Posture*. 2010 Jul;32(3):336-41. ## **AUTISM – A TREKKING PROGRAM TO IMPROVE HEALTH PROFILES**

CORREIA, N., VIDAL, H., FREITAS, P.

*APPDA NORTH*

The autism spectrum disorder (ASD) is a chronic and severe pervasive neurodevelopmental disorder characterized by 3 specific symptoms: reduced social interaction; impairments in reciprocal communication; and repetitive-stereotyped behavioural patterns (APA, 2002). The prevalence of deficits on motor behaviour and the risk of inactivity due to specific features are elevated, being two of the most common co-morbidities in ASD. Owing to these co-morbidities, people with ASD are a very high group risk. There is a, real and significant, decay on their health, longevity and quality of life. Health profits of regular exercise are well recognized in literature (Booth, Gordon, Carlson, & Hamilton, 2000). Current recommendations name that people: should engage in at least 60 minutes or more of developmentally appropriated physical activity every day or most days of the week or should be active every day, including 20 minutes bouts of continuous, moderate to vigorous physical activity, 3 or more times per week. Research has established a positive impact of exercise programs on behavioural outcomes in people with ASD increasing exercised capacity and caloric expenditure, which could improve or control health profiles (Beets, 2007). APPDA North develops a sports training program to service users, which is developed on a weekly basis, providing a full training program targeted to their needs. The central activity is TREKKING and the main goal is to decrease the risk factors presented by this population (obesity, heart disease, type 2 diabetes, and epilepsy), due mainly to: inactivity, medication and aging. The trekking program is developed in 2 different subprograms: (i) daily (Monday to Friday) trekking program with 45 minutes length every day and (ii) weekly (developed once a week on Wednesdays) trekking program with 3 hours length. The subjects are adults with ASD, age 18 to 43 years, mainly males and nonverbal. Two groups were established, Group 1 composed by 6 adults age 25 to 43 years, presenting all the risk factors and Group 2 composed by 24 adults age 18 to 43 years, presenting some risk factors. Group 1 participates on both programs (i and ii) and Group 2 participates only on the weekly trekking program (ii). Weight, blood pressure and heart-beat are accessed every week. Results show us that these programs have good results in controlling the risk factors, improving the subjects' health and quality of life in both groups. APA (2002). ## **NEW DATA ABOUT LATERALITY OF PEOPLE WITH INTELLECTUAL DISABILITY**

NIORT, J., DR HERNÁNDEZ, J., DR BOFILL, A.

*INEFC-UNIVERSITY OF BARCELONE*

Introduction This study exposes a communication about laterality in people with fragile X syndrome (SXF), based from the works of McManus & Cornish (1997) and of Cornish, Pigram & Shaw (1997) about fragile X syndrome and also from the works of Carlier & col. (2006) and of Gérard-Desplanches & col. (2006), about others intellectual handicaps. The people with intellectual disabilities may be left-handed or ambidextrous. In the works of Cornish, Pigram & Shaw (1997), the people SXF are preferably left-handed regarding group of people with Down's syndrome and control group. In the works of McManus & Cornish (1997), the people SXF are right-handed and resemble the control group of people without handicap. Methods The study groups are composed by 30 people (15, 2 years), another group composed by 34 people with intellectual disabilities (16, 5 years) and a group composed by 160 people without disability (14, 7 years). The method is the test of handedness preference by Annett (1970) adapted for this study. It added three proves for measuring footedness, two proves for eyedness and one for eardness. Results The results of this experience confirm the preference of right-handedness (93, 3 %) in people with syndrome fragile X and provide new data regarding footedness and sensorial laterality of these people. They submit inconsistent footedness and ocular cross laterality. The people with syndrome fragile X are different from the people with other intellectual disabilities (73, 5 % right-handedness) and they resemble the people without intellectual disabilities. Discussion The results are in the same way than the works of McManus & Cornish (1997). It's not possible explain why the group of people with syndrome fragile X is different from group with other intellectual disabilities but get attention that the syndrome fragile X is a syndrome linked with the chromosome X and is hereditary. ### A TEST TO EVALUATE SPORT SPECIFIC ABILITIES OF INTELLECTUALLY DISABLED ELITE ROWERS.

VARALDA, C., GRIZZETTI, P., CAPRANICA, L., PIACENTINI, M.F.

ITALIAN ROWING FEDERATION

A test to evaluate sport specific abilities of intellectually disabled elite rowers. Varalda C1, Grizzetti P1, Capranica L2, Piacentini MF2. Italian Rowing Federation, Rome, Italy 2 DISMUS, University of Rome Foro Italico, Italy Introduction Only three sports will include athletes with an intellectual disability (ID) in the 2012 Paralympic games while rowers with ID should be included in the 2016 Paralympic Games. Due to the fact that intellectual disability of athletes is measured on the basis of an internationally recognized IQ test (www.inas.org), the purpose of the present study is to propose a novel rowing test (Varalda Adapttest) to evaluate sport specific abilities of intellectually disabled rowers. Methods Thirty-four (F:17, M:17; age: 24±10yr) adapted and 5 elite (F:2, M:3) rowers performed the Varalda Adapttest, which includes three 1-min steps at a 28, 32, and 28n/min stroke cadence, respectively. Variability in stroke cadence and acceleration (i.e. range and delta between peak and average values) were measured by means of an accelerometer (Free Sense, Sensorize, Italy) positioned on the ergometer seat. A 2 (groups)x 2 (gender) x3 (steps) ANOVA for repeated measures was used to ascertain differences ( $p<0.05$ ). Results For stroke cadence, 59% of the adapted rowers failed to maintain the requested stroke cadence during the 1st step, 53% during the 2nd and 50% during the 3rd steps respectively. Regarding acceleration, differences ( $p=0.002$ ) for range emerged between groups (elite  $2.04\pm1.70$  m/s<sup>2</sup> adaptive  $1.92\pm0.75$ m/s<sup>2</sup>). Between steps only the elite showed significant differences between the first ( $3.25\pm1.05$  m/s<sup>2</sup>) and the other 2 steps ( $1.98\pm2$  m/s<sup>2</sup> and  $1.99\pm1.50$  m/s<sup>2</sup> respectively). Delta acceleration was constant ( $0.48\pm0.2$  m/s<sup>2</sup>) for adapted athletes, whereas elite rowers showed significantly higher values during the 1st step ( $0.5\pm0.2$ m/s<sup>2</sup>) with respect to the following ones ( $0.28\pm0.08$ m/s<sup>2</sup> and  $0.23\pm0.18$ m/s<sup>2</sup> respectively). Discussion Adapted rowers show a high variability in rowing cadence and acceleration. In fact, more than half of these athletes were unable to observe the required cadences. These findings support the use of the Varalda Adapttest for classifying athletes with intellectual disabilities on the basis of their sport specific abilities. Acknowledgments: We would like to thank Sensorize, Italy

### WHEELCHAIR DANCE SPORT: PHYSICAL AND SOCIAL CHANGES FOR PEOPLE WITH PHYSICAL DISABILITIES

ROCHA FERREIRA, M., FERREIRA, E.L.

UNICAMP; FEDERAL UNIVERSITY OF JUIZ DE FORA UFJF

This study focuses on wheelchair dance sport for people with physical disabilities. It is a modality in expansion in Brazil and in the world, with several national and international tournaments. The aims of this research are: a) to find out the senses of dance for people with physical disabilities, b) to understand the contribution of wheelchair dance sport for the group studied, c) to understand the role of wheelchair dance as a possibility to physical and social changes. METHOD. The method was done through qualitative research, with the wheelchair dancer groups associated to the Brazilian Confederation of Wheelchair Dance. The information was obtained through choreography video archives from different regions of Brazil. Furthermore, it was carried out formal interviews with dancers and choreographers of these groups during their presentations in the national events, from the years of 2001 to 2010. RESULTS AND CONCLUSIONS The wheelchair dance sport gives new perspectives of life for the studied group. They perceive an improvement in health and in social relationship. The dance permits the exercise of citizenship and gives a place where the disabled dancer uses its subjectivity and builds up his identification. There has been an attempt to overcome the individual ethics put by the dance into a more cohesive ethics. Hence, this research brings essential contributions for understanding dance in a wheelchair to the physically handicapped person, and in return contributes to a better understanding of what is the dance in itself. It indicates dance as an instrument of non-verbal language that allows the understanding of the communicability of the senses meant by the body.

### THE IMPORTANCE OF MOTOR STIMULATION WITH SPECIFIC MEANS OF PHYSICAL EDUCATION AND SPORT APPLIED TO THE CHILD WITH SEVERE MENTAL DISABILITY

SUTA, V.E.N.2, MARINESCU, G.1, BALAN, V.1, PETRISOR, L.1, TICALA, L.1, PAUNESCU, M.1, DUMANGIU, M.1, TATARU, T.1, SUTA, L.I.2

1: UNEFS (BUCHAREST, ROMANIA), 2: SPECIAL SCHOOL NO. 11 (BUCHAREST, ROMANIA)

THE IMPORTANCE OF MOTOR STIMULATION WITH SPECIFIC MEANS OF PHYSICAL EDUCATION AND SPORT APPLIED TO THE CHILD WITH SEVERE MENTAL DISABILITY Suta, V.E.N.2, Marinescu, Gh.1, Balan, V.1, Chesnoiu, L.1, Ticala, L.1, Paunescu, M.1, Dumangiu, M.1, Tataru, T.1, Suta, L.I.2 1: UNEFS (Bucharest, Romania), 2: Special School no. 11 (Bucharest, Romania) Introduction The research aims to demonstrate that the students with severe mental disability can enhance their movement ability, through the development and implementation of a motor stimulation program, with the duration of a school year, adapted to the biometrical potential of these students. Methods The reference study, the test method and statistical - mathematical data processing methods were used to carry out the research. The biomotor standardized tests used to evaluate the subjects were The Biomotor Potential of the Romanian School Population, the Brockport Test Battery, the Motorin Test and the Flamingo Balance Test of Eurofit Test Battery. To process the collected data we used a statistical mathematical program called SPSS 16 for Windows and we chose to apply Wilcoxon Test as well as the effect of the size index on two identical samples, reporting ourselves to a significance level of  $p<0.05$ . Results After we implemented the intervention program during the school year 2009 - 2010 there were significant statistical differences between the values obtained at the initial evaluation and the final evaluation for the tests aiming the arm and leg coordination, overall coordination and balance. All the students with severe mental deficiency involved in the program have obtained better values to the tests which targeted the coordination skills. At the end of the stimulation program, students with severe mental disability and an IQ between 40 and 49 who have used specific means of the aerobic gymnastics obtained an improved level of the motor conditional quality endurance. Discussion In conclusion, students with severe mental disability are a category of subjects who can be educated in terms of motor performance. We propose the introduction in the Romanian curriculum of a minimum of three weekly Physical Education lessons for the students with severe mental deficiency. Also, Physical Education lessons should be carried out with groups of students with a close motor potential and level of understanding. The annual design and planning of the curriculum should start from the biometrical potential diagnosed on the initial evaluation and the stimulation program needs to address the poor components of the motor ability. ## LEARNING A DYNAMIC BALANCE TASK EVEN THOUGH SUFFERING FROM PARKINSON'S DISEASE WITHIN AN OBSERVATION PERIOD OF 6 WEEKS

WAGNER, P., STREICHER, H., ECKERT, K., BEER, A.

UNIVERSITY OF LEIPZIG

**Introduction** Retaining the mobility is a main keyfactor to keep a good quality of life up to an old age. A proper dynamic balance plays an important role in this. Postural instability is one of the main symptoms by patients with Parkinson's disease (PD) (Visser & Bloem, 2005). The aim of the study is to evaluate firstly if it's possible for affected patients (PD) to learn and stabilize a dynamic balance task and secondly how strong can they improve in comparison to a coeval control group. **Methods** Seven PD-patients (1♀; 6♂; age M=62,71; SD=5,21) and fifteen coeval controls (6♀; 9♂; Alter M=65,2; SD=6,38) were involved in the study. Both groups were confronted with a pendalons stabilometer platform task over a period of time of six weeks (one session per week). Each training session consists of 15 repetitions, 30 seconds each with two-minutes breaks. The participants had to deal with the challenge to balance a free-running (in a plane) pendalons stabilometer platform as long as possible for max. 30 seconds within a predetermined interval of 5 °. The time in balance (TBL) has been measured. The overall kinematic parameters of the board movement were counted up (acceleration and deceleration profile of the deflection of the platform) to measure the deflection in total for further analysis purposes. The general linear model with repeated measures with the within-subject factors of training days and group affiliation were chosen as statistical approaches. **Results** Both groups showed significant improvements in the TBL throughout the learning process (PD patients: M1=8.11s, SD1=1.56s; M6=11.02s; SD6=3.50s; controls: M1=10.56s; SD1=3.59s; M6=16.53s; SD6=6.70s,  $p < 0.05$ , e.g. M1  $\triangleq$  mean training session 1). PD-patients reached a significant lower base level (t1) in comparison to the control-group ( $p < 0.05$ ). Subsequently, the PD-patients were able to keep the balance on average as long as the coeval controls at t1 at final testing (t2). **Discussion** The results are first indicators that the possibility to train motor abilities is given in old adulthood as well as for people suffering from Parkinson's disease. **References** Visser, JE, Bloem, BR (2005). Neural Plasticity, 12 (1-2), 161-174.

## THE COMPARATIVE DAILY PHYSICAL ACTIVITY BETWEEN MENTALLY CHALLENGED BOYS AND HIGH SCHOOL BOYS IN JAPAN

OHASHI, C., KANEKO, R., MATSUI, S., HIBI, N.

TOYAMA NATIONAL COLLEGE OF TECHNOLOGY

**Introduction** Previous studies have indicated that mentally challenged children have low physical fitness levels, with the main factor being that they do not have an adequate amount of physical activity in their daily lives. But actually there has not been much research about this within Japan. The aim of our study is to illustrate the condition of physical activity in mentally challenged children in Japan. In this first step, we have measured the quantity of daily physical activity in mentally challenged students and compared it with students who go to regular high school. **Results** The subjects of this study are 7 boys who go to a special needs education school for the mentally challenged (S-group) and 8 boys who go to regular high school (H-group) in Japan. We measured their quantity of physical activity by a pedometer (Lifecorder) for 2 weeks, and compared weekdays and weekends of physical activity between S-group and H-group. On weekdays, there was no significant difference in physical activity in the number of steps ( $9749 \pm 2457$  vs  $9116 \pm 4338$ ), walking times ( $86.6 \pm 24.9$  vs  $84.3 \pm 37.8$ ), running times ( $8.8 \pm 4.8$  vs  $7.0 \pm 6.1$ ). On weekends, S-group's physical activity was significantly lower than H-group in the number of steps ( $4928 \pm 2373$  vs  $10696 \pm 4798$ ,  $p < 0.05$ ), walking times ( $48.4 \pm 21.6$  vs  $99.7 \pm 49.0$ ,  $p < 0.05$ ), running times ( $0.8 \pm 0.5$  vs  $10.4 \pm 4.0$ ,  $p < 0.001$ ). **Discussion** It is said that mentally challenged children are inactive in their daily lives, but in our study, there was no significant difference between mentally challenged children and high school students in their physical activity from Monday to Friday. This is due in part to a difference in the curriculum for students with special needs. Specifically, there are 4 physical education classes a week in schools for special needs. On the other hand, there are only 2 classes a week in high school. However, mentally challenged students performed much lower physical activity than the high school students on weekends. It is important to support the maintenance of children's physical activity on weekends and especially long holidays like during summer vacation. This support should be in cooperation with teachers and family in order to prevent decline in the student's physical strength and weight gain. After leaving school it will be necessary for students to maintain a certain amount of physical activity to keep being healthy. Therefore, we must use their schooling years to develop healthy routines that will last throughout their lives.

## PHYSICAL EDUCATION TEACHERS' PERCEPTIONS OF AND ATTITUDES TOWARDS PUPILS WITH SPECIAL EDUCATIONAL NEEDS

HERNANDEZ, J.I., BOFILL RÓDENAS, A.I., NIORT, J.I

I: INSTITUT NACIONAL D'EDUCACIÓ FÍSICA DE CATALUNYA.

**Introduction** The aim of this study is to gain deeper insight into physical education teachers' perception of their pedagogical strategies when working with pupils with special educational needs (SEN), a concept that in this context encompasses both disabled pupils and those with behavioural disorders. To this end, we examined the attitudes and opinions of a sector of physical education teachers employed at secondary schools in Barcelona (Spain). **Methods** The sample was obtained from the population of physical education teachers at secondary schools in the province of Barcelona (N=339), the total sample amounting to N=57. The questionnaire on which the study was based was formulated by a team of experts in the field. The questions were grouped into three categories: characteristics of the teachers; teachers' pedagogical strategies; and external factors. The questionnaire, once administered and validated (N=45), was shown to have a reliability range of between 0.85 and 0.90. **Results** The literature reviews showed consistent evidence for the direct relationship between different items studied. The analysis of and conclusion drawn from the results present the variables that the teachers regarded as important when it comes to improving attitudes to the integration of such pupils into the educational system. **Discussion** The qualities teachers require to work with SEN pupils are empathy, patience, a sense of ethics and educational experience. Integration of such pupils is favoured and reinforced firstly by flexible grouping and secondly by group splitting and adaptation of curricula. As a complementary factor, adapted facilities, materials and hygiene services foster SEN pupils' participation in activities on an equal footing with the rest of their classmates. **References** Avramidis, E. and Kalyva, E. ### PP-PM22 Physical Activity Promotion and Assessment

#### DIMENSIONS OF PHYSICAL ACTIVITY EXPECTATIONS: IMPLICATIONS FOR DESIGNING AND MARKETING EXERCISE

BRAS, R.1, RODRIGUES, R.G.2, PINHEIRO, P.2, ESTEVES, D.1, O'HARA, K.1

(1)UNIVERSITY OF BEIRA INTERIOR/CIDESD (COVILHÃ, PORTUGAL); (2)UNIVERSITY OF BEIRA INTERIOR/NECE (COVILHÃ, PORTUGAL)

Introduction: Gyms, swimming pools and clubs are selected by many individuals as the place where to practice physical exercise. Normally exercise program providers are privately-held businesses, which success depends on satisfying their customers. Knowing what their customers expect from the practice of exercise allows exercise programs providers to design more motivating exercise programs (Peterson et al., 2006). Therefore, the aim of this study was to determine major motivation factors to be physically active, and to assess the perceived relative importance of these motivation factors. Methods: The study included 745 individuals (35.0±19.6 years). A survey designed to assess the expectations of individuals when doing exercise, on interview form, using Likert scales (1-5). A principal components analysis was performed, and descriptive statistics of the components computed, which were compared using paired samples t-tests. Results: Kaiser-Meyer-Olkin was 0.84, Bartlett's test of sphericity was significant, and the Measures of Sampling Adequacy of the original variables were all above 0.67. Four components were extracted using Varimax rotation, explaining 71% of total variance. First component represents Performance (21% of variance), the second Enjoyment (20%), the third Beauty (15%), and the fourth Health (15%). Health has the highest mean (4.45) and the lowest standard deviation (0.73), followed by Enjoyment with 3.63 (0.91), Performance with 3.38 (0.97), and finally Beauty 2.89 (1.31). Beauty is the only factor with "negative" mean, below 3, the indifference point. All means are statistically different ( $p < 0.05$ ) from each other. Discussion: When design and marketing their exercise programs, exercise programs providers should take into consideration that the most important factor for individuals is Health. These results suggested that programs should seek and show important health benefits for participants, according Mears and Kilpatrick (2008). But also very important is Enjoyment. Exercise programs providers should have fun programs that enhance socializing between participants. Beauty reasons are less important in general. Nevertheless one should note that the large standard deviation indicates that individuals are very different in what respects to the Beauty aspects of exercise practice. There may be a niche market for individuals who value Beauty. References: -Mears, J & Kilpatrick, M (2008). Motivation for exercise: Applying Theory to Make a Difference in Adoption and Adherence. #### THE POSSIBILITY TO MONITOR PEAK PERFORMANCE WITH AN ONLINE TRAINING DIARY: A CASE STUDY

PIACENTINI, M.F., DI CASTRO, A., DE IOANNON, G., CAPRANICA, L., MEEUSEN, R.

UNIVERSITY OF ROME-FORO ITALICO

The possibility to monitor peak performance with an online training diary: a case study Piacentini MF1, Di Castro A1 De Ioannon G1 Capranica L1 Meeusen R2 IDISMUS, IUSM, Rome Italy 2Dpt of Human Physiology, VUB, Belgium Triathlon is a multidiscipline endurance sport with a sequential swim, cycle, and run phases. Monitoring multidiscipline sports is complex. The use of online training diaries has been used in the prevention of non functional overreaching-NFOR (Piacentini et al. 2008, 2009) by monitoring subjective parameters of training (BLITS®) but never used to predict peak performance in athletes. Therefore, the purpose of the present study was to monitor 10 weeks of training of an elite triathlete prior to an important competition. Methods A female elite triathlete (23 yrs) filled in an online training diary (BLITS®) for 10 weeks, and a weekly Profile of Mood states (POMS). Subjective data regarding training are reported on a 10 cm visual analogue scale (VAS). Quantification of, and adaptation to training were measured by training load (TL: intensity x duration), monotony of training (day by day variability in training), and strain (load x monotony). Moreover, we visualized with only one parameter the subjective response to training (BLITS®). During these 10 weeks the athlete competed mainly in duathlon races (run-cycle-run). Performance was evaluated by a 2x2km time trial (95-100% lactate threshold speed) during a combined cycle-run training. RESULTS Performance significantly increased (from an average of 8'12"50 to 7'39"50 in the 2x2km test) in the 10-week period. Total mood improved by 17% over the whole period. POMS subscales showed a decrease in depression (-33%), tension (-42%) and anger (-20%) and an increase in fatigue (15%) and vigor (6%). Motivation to train increased by 39% from the first to the 10th week of training. Strain increased significantly after 3 weeks of intensive training (by 119%) and thereafter started to decrease while TL remained constant. BLITS® showed an increase (23% at week 6) and thereafter decreased by 100% the week before competition. DISCUSSION A steady increase in BLITS® indicates maladaptive responses to training, extreme fatigue and negative mood. In the present study, BLITS® decreased by 100% the week prior to competition, indicating a positive adaptation to training, and a decrease in total mood. Strain increased until the 3rd week and thereafter started to decrease despite the TL remained constant. This suggests that monotony of training decreased, data supported by the high motivation to train the athlete demonstrated. These data indicate that the use of the BLITS® online training diary is a valuable tool also for predicting peak performance. REFERENCES Piacentini MF et al ECSS 2008 pg 300 Piacentini MF et al. ECSS 2009 pg 227

#### A COMPARISON OF VISUAL ANALOGUE SCALE MEASURES IN FREE-LIVING, WEIGHT-LOSING ADOLESCENTS.

DUCKWORTH, L.

LEEDS METROPOLITAN UNIVERSITY

Lauren C Duckworth<sup>1</sup>, Roderick FGJ King<sup>1</sup>, Andrew J Hill<sup>2</sup> and Paul J Gately<sup>1</sup>. <sup>1</sup>Carnegie Faculty, Leeds Metropolitan University, Fairfax Hall, Headingley Campus, Leeds, UK. <sup>2</sup>Academic Unit of Psychiatry and Behavioural Sciences, Leeds University School of Medicine, UK. Introduction: The use of visual analogue scales (VAS) has been established for the quantitative measurement of subjective experiences in both exercise and nutrition intervention studies. Collecting data at several time points to produce a temporal profile can provide information on appetite in response to a pre-load, meal or diet/exercise intervention programme. In addition, the increasing cost-effectiveness and reliability of hand-held computers has encouraged the development of electronic rating systems. The aim of this study was to compare the type and timing of ratings of appetite and mood in free-living overweight and obese children attending a residential weight-loss

camp. Methods: Participants: 44 overweight and obese children (BMI  $34.3 \pm 5.7$  kg/m<sup>2</sup>, age  $14.5 \pm 1.8$  years). Intervention: An eight-week (max) programme of physical activity, reduced-energy intake and behaviour change education. Assessments: Participants completed the two types of assessment at the beginning and end of their camp stay. Across-the-day ratings were made before and after each meal and at two hours post meal (9 timepoints) using a hand-held electronic rating system. These ratings were averaged to provide a single score for comparison. End-of-day ratings were paper questionnaires measured using a 0-100mm scale. Results: All end-of-day ratings correlated significantly with across-the-day ratings at both pre ( $r=0.32-0.74$ ) and post ( $r=0.31-0.73$ ) camp. However, there were significant differences between measurement tools with mean values for across-the-day ratings showing a narrower range than end-of-day ratings (68mm vs. 96mm respectively;  $p<0.05$ ). In assessing pre-meal ratings: hunger and desire to eat showed a moderate increase across the day and fullness decreased; a pattern which had disappeared by the end of camp. Discussion: These findings show the merits of both assessment approaches in a free-living environment. Across-the-day ratings are relatively labour intensive but provide detailed profiles of appetite/mood that vary meaningfully over the waking hours. End-of-day ratings are simple to administer, describe overviews of appetite/mood that can be collected prospectively, and are as sensitive as averaged across-the-day ratings. Inter-changeable use of these approaches however is not advised given differences in precision at rating scale end-points.

#### RELATIONSHIP AMONG PHYSICAL ACTIVITY AND EPICARDIAL ADIPOSE TISSUE IN POST-MENOPAUSE.

D'ANGELO, E.1, ODOARDI, A.1, RUGGIERI, B.1, DI DONATO, E.1, IZZICUPO, P.2, RIPARI, P.1, NAPOLITANO, G.2, DI BALDAS-SARRE, A.2, GALLINA, S.1

G. D'ANNUNZIO UNIVERSITY

Introduction Epicardial adipose tissue (EAT) is the fat deposited under the visceral layer of pericardium and may be considered as ectopic fat. Studies suggest that visceral adipose tissue and EAT have the same origin, and both are strongly related to the development of coronary artery disease. Sedentary lifestyle promotes the storage of ectopic adipose tissue whereas high physical activity (PA) level prevent its accumulation. PA may be expressed as metabolic equivalents (METs) or Steps and ACSM guidelines recommend 10.000 steps per day to be active, for most healthy adults. Aim of the study was to investigate the relationships between main parameters of PA and EAT, in sedentary post-menopausal women. Methods Fifty-five post-menopausal women ( $57.4 \pm 4.7$  years) without history of physical exercise and cardiovascular diseases were recruited after initial screening including medical history. EAT was measured by echocardiography. Total daily energy expenditure (TEE), mean daily PA intensity, daily steps, and both daily time and daily energy spent on PA with intensity  $>3$  METs were measured by the SenseWear Pro 3 Armband. Physical activity level was calculated as the TEE/basal metabolic rate ratio. Own software calculated the daily steps spent above and below the intensity of 3 METs (steps  $>3$  and steps  $<3$ , respectively). Cardiovascular risk (CVR) was calculated by "PROGETTO CUORE" equation. Results Steps  $>3$  was inversely correlated with EAT independently steps  $<3$  ( $r=-0.279$ ,  $p=0.04$ ,  $r=-0.438$ ,  $p=0.01$ , semi-partial and zero order correlation respectively). No correlation was found among EAT and the other parameters of PA. Further, there was a direct correlation between EAT and CVR ( $r= -0.403$ ,  $p<0.001$ ). Conclusion In post-menopause active lifestyle is the way to prevent the storage of EAT and then CVR. In particular the quantity of PA above a specific intensity, expressed as steps  $>3$ , might plays a central role.

#### IS UNIVERSITY A GOOD ENVIRONMENT FOR PHYSICAL ACTIVITY?

RUIZ TENDERO, G.

COMPLUTENSE UNIVERSITY OF MADRID

Ruiz, G.1, De-Vicente, E.2, Vegara, J.2 1: UCM (Madrid, Spain), 2: UCAM (Murcia, Spain). Introduction Physical activity (PA) is considered a fundamental link by the World Health Organization for control of non-communicable diseases (World Health Organization, 2004). Workplace is recognized internationally as a framework for the study and promotion of health (Boslaugh, Kreuter, Weaver, Naleid, & Brownson, 2005). The aim of this study is to quantify, using pedometers, PA levels in different professional layers of a university campus. Methods The sample is composed by 77 participants (19-50 years old) recruited from 4 groups on a Spanish University Campus: students ( $n=33$ ), teachers ( $n=17$ ), administrative officers ( $n=13$ ) and cleaning staff ( $n=14$ ). Yamax Digi-Walker, sw.630 model was the instrument used to record steps for four consecutive days (from Thursday to Sunday). The instrument and time period selected have been established as valid in scientific literature (Kang, et al., 2009). Results The results show a characteristic pattern common to all strata, determined by the decrease of PA during the weekends. Cleaning staff is the most active group in working days ( $p<.05$ ). No PA differences were found comparing groups (students plus professors together) belonging to different areas of study (Sport Sciences vs. Architecture and Engineering), but analyzing Sport Science students separately, they were found to be the most active in teaching hours. ( $p<.05$ ). Except for the administration sector, the other groups are meeting the daily recommendations of PA according to the steps. Discussion Comparing our data with Tudor and Bassett's study (Tudor-Locke & Bassett, 2004), the university sample described can be considered as very active ( $>12.500$  daily steps). Depending on the day (working day or weekend), similar results were found in other studies (Miller & Brown, 2004; Ruiz, Salinero, Webster, & Aznar, 2006), in whom PA was higher in working days. #### BARRIERS AND FACILITATORS FOR THE REGULAR PRACTICE OF PHYSICAL ACTIVITY IN WHITE AND PAKISTANI TODDLERS

COSTA, S., CLEMES, S., BARBER, S., AKHTAR, S., VARELA-SILVA, M.I., GRIFFITHS, P., CAMERON, N.

LOUGHBOROUGH UNIVERSITY

BARRIERS AND FACILITATORS FOR THE REGULAR PRACTICE OF PHYSICAL ACTIVITY IN WHITE AND PAKISTANI TODDLERS Costa S.1, Clemes S.1, Barber S.2, Akhtar S.2, Varela-Silva M.I.1, Griffiths P.1, Cameron N.1 1: Loughborough University (UK), 2: Born in Bradford Cohort Study (UK) Introduction Childhood obesity is a worldwide public health problem. Regular physical activity (PA) is protective against numerous

chronic diseases, while time spent in sedentary behaviours (SB) is considered an independent risk factor for many illnesses. UK South Asians are at higher risk for several chronic diseases, and are also reported as less active than Whites (Fischbacher et al, 2004). The preschool age is considered a crucial period of life for the establishment of lifestyle behaviours such as PA and SB. Research has cited various personal (personality), interpersonal (parents' lack of time), and organizational (childcare activities) or community (neighbourhood safety) influences on young children's PA (Dwyer et al, 2008). In order to design policies and interventions targeting PA and SB in young children, knowledge of the facilitators and barriers for the practice of PA is vital. The aim of this research was to assess barriers and facilitators for the regular practice of PA in an ongoing study of White and Pakistani toddlers from Bradford. Methods Five focus groups (N= 3 to 6 per group) were performed to date with White and Pakistani mothers of 2-3 year olds, at Children's Centres (CC) that offer local support for families of children under 5 years of age (e.g. childcare; early education). The focus groups were conducted in English or Urdu. Audio recordings were transcribed verbatim and analysed following a Thematic Analysis approach. Results Across all focus groups, lack of time and high cost of activities were the main barriers identified by mothers to take the toddlers to activities available in the community. A need to take transport to activities and bad weather (Winter) were also identified as major barriers, the latter being mentioned more strongly by Pakistanis. Free of charge activities, available crèche/babysitter and someone to help during activities were reported as the main facilitators. Furthermore, playgroups available at CC were highly valued and regularly attended by all mothers. Discussion Main reported barriers represent interpersonal, organizational and community factors, with little variation between ethnicities. Playgroups available at CC have great potential as an intervention tool targeting both mothers and toddlers' PA, as they address many of the reported barriers. Additionally, CC are already part of these mothers' routines, reducing additional burdens and risk of mistrust from the mothers, especially Pakistanis (Bhopal, 1998). ### THE RELATIONSHIP OF PARTICIPATION MOTIVATION TO FITNESS IN CHILDREN AGED 9 AND 10 YRS

SERBETAR, I., NIKOLIC, I., TOPLEK, N.

*FACULTY OF TEACHER EDUCATION ZAGREB*

**Introduction** Since low level of fitness, associated with childhood obesity, is a major public health concern there is growing interest in all of the factors which could influence children's participation in exercise. Motivation for exercise is recently among the most important ones. We tried to establish the relationships between different levels of motor fitness and intrinsic motivation in children aged 9 and 10 yrs. **Methods** Seventy sixth children aged 9 and 10 yrs participated in study. Motor fitness was assessed using the 6 motor, 1 functional and 5 anthropometry tasks. Body mass index as well as sum of skinfolds were also calculated. Intrinsic motivation was evaluated with the Participation Motives Inventory (PMI; Gill et al., 1983). Fitness scores were standardized and summarized in overall motor score, based on that score children were further divided into low, average and high ability group. Differences according to gender were established in both domains. Cronbach ALPHA was calculated to establish the consistency of PMI scales. ANOVA were used to determine the differences in motivation for participation between low, average and high motor ability groups. Results Children differentiated by gender in three motor and one functional test in favor of boys. There was also differences in motive subscales "team" and "skill/mastery" – in both boys scored higher. Overall children scored higher in subscales "skill/mastery", "avoidance of boredom", "achievement" and "team". ANOVA established differences between low, average and high motor ability groups in participation motivation. Namely, low and average groups scored the same but high ability groups showed significantly higher values in "skill/mastery" ( $F=4.64$ ;  $p=.01$ ), "fitness" ( $F=4.78$ ;  $p=.01$ ), and "team" ( $F=4.11$ ;  $p=.02$ ) subscales. In high ability group BMI was significantly lower than in other groups. Cronbach ALPHA coefficients were rather low and ranged from .31 to .66. **Discussion** The results indicate that to have fun was not the only reason for participation in exercise. Although rankings varied all three groups identified similar motives for participation. Children with better fitness performance showed higher motives for participation than children with lower fitness scores. References Gill, D., Gross, J., & Huddleston, S. (1983). Participation Motivation in Youth Sports. *Int Jour of Sp Psych*, 14, 1-14.

### ATTITUDES TOWARD PHYSICAL EDUCATION OF ALBANIAN SECONDARY SCHOOL STUDENTS

LALAZI, Y.

*UNIVERSITY OF SPORTS OF TIRANA*

**Abstract** ATTITUDES TOWARD PHYSICAL EDUCATION OF ALBANIAN SECONDARY SCHOOLS STUDENTS Lalazi, Y.1, Lile, A.1, Rizvanolli, V.1, 1: UST (Tirana, Albania) **Introduction** The goal of this study was to investigate attitudes toward physical education preferences in Albanian secondary high school students. Several studies (Colley, & Berman, & Millingen, 2005; Wersch, & Trew, & Turner 1992) reported that high school boys had a higher positive attitude toward PE compared to girls. **Methods** Participants of this study consisted of 197 students from seven and eight secondary general schools of Tirana, Albania. In The participants were 102 girls ( $M = 12.69 \pm 0.79$ ) and 95 boys ( $M = 12.64 \pm 0.71$ ) aged 12 to 14. An instrument of the Attitude Toward PE Scale for Albanian students with 12 items with 5-point Likert-type scales was developed. Statistical analysis was performed using the SPSS package for windows, version 17.0. Analyses of Variance (ANOVA) was used to determine differences in attitude toward PE between girls and boys. Results The alpha reliability coefficient of the Attitude Toward PE Scale developed was .78 indicating that the instrument was reliable. 91% of students have positive attitude toward sport leisure, 36% where participants in the school team or school sports events, 87% were satisfied from the PE class, 37% stated that tools and equipments were not sufficient etc. The PE attitude mean scores of boys ( $M = 3.98$ ) were higher than those of girls ( $M = 2.99$ ). Results revealed a significant gender difference in high school students attitudes toward PE ( $F = 29.869$ ;  $p < 0.01$ ). **Discussion** Results of this study indicated that Physical education course syllabus should be enhanced in order to enable students to obtain necessary skills and attitudes for a healthy life style. Findings of this study had also shown that there was a significant difference related to gender, where boys have more positive attitudes toward PE class and leisure activities than girls. References Colley, A., Berman, E. & Van Millingen, L. (2005) Age and Gender Differences in Young People's Perceptions of Sport Participants, *Journal of Applied Social Psychology*, 35 (7), 1440-1454. ## PHYSICAL ACTIVITY LEVELS AND DETERMINANTS TO PRACTICE ACCORDING TO AGE IN GIRLS THAT ATTENDED PORTUGUESE PUBLIC SCHOOLS

MARTINS, J., MARQUES, A., SARMENTO, H., MARTINS, M., COSTA, J., ONOFRE, M., CARREIRO DA COSTA, F.

TECHNICAL UNIVERSITY OF LISBON, FACULTY OF HUMAN KINETICS

**Introduction:** The percentage of children and adolescents presenting low levels of physical activity (PA) is cause for great concern, and girls are a group with particular risk of inactivity. **Objective:** This study aimed to examine the relationship between perception of competence, goal orientation, attitude towards school and Physical Education (PE), PA participation, and the ages of girls that attended Portuguese public schools. **Methods:** A total of 2270 girls, aged from 10 to 18, participated in the study. They attended 6 Basic and Secondary schools from 5th to 12th grade. The girls were separated into 3 groups according to their age: 10 to 12 (1071 girls – 47.2%), 13 to 15 (753 girls – 33.2%) and 16 to 18 (446 girls – 19.6%). Data was collected using a questionnaire. ANOVA was used to analyse the effect of age in the attitude towards school. Kruskal-Wallis was used to analyse the effect of attitude towards PE, perception of competence, goal orientation and PA participation according to age. Significance level was  $p < 0.05$ . **Results:** The perception of competence decreased with age and significant differences were found between all age groups ( $X^2KW(2)=19.092$ ,  $p < 0.001$ ). The same trend was observed concerning ego orientation, with significant differences between all groups ( $X^2KW(2)=56.970$ ,  $p < 0.001$ ). As for the task orientation the average value increased from 10-12 years to 16-18 years. Kruskal-Wallis revealed that the youngsters differed from the others ( $X^2KW(2)=10.806$ ,  $p=0.005$ ). Regarding subjects' attitudes, 58% and 70 % of the girls showed a positive attitude both toward school and PE. In the first case, ANOVA showed no significant differences between the groups ( $F(2,1267)=0.711$ ,  $p=0.491$ ). However, we observed that their attitude towards PE had decreasing tendency, with significant differences between all groups ( $X^2KW(2)=75.717$ ,  $p < 0.001$ ). Concerning informal and formal PA participation, respectively, 47% and 23% of the girls have reported to practice every week or every day. Nevertheless, an accentuated decrease was observed as the age increased, presenting the 16-18 years group the lower values for PA participation. Through comparative analysis among age-groups, there were significant differences in informal participation ( $X^2KW(2)=55.687$ ,  $p < 0.001$ ). **Conclusion:** Low levels of PA participation are particularly marked among adolescent girls, suggesting they are at risk. The low levels of perceived competence and a weak attitude towards PE, seem to explain these results. Schools and PE professionals should be able to build up an educational climate to promote a positive attitude towards PA and encourage activity, considering specific strategies for risk groups.

## INFLUENTIAL FACTORS OF CHOOSING SPORT IN CHILDHOOD

REVESZ, L., BOGNAR, J., GECZI, G., TRZASKOMA-BICSERDY, G., SOS, CS.

SEMELWEIS UNIVERSITY FACULTY OF PSYCHICAL EDUCATION

**Introduction** Sport experts are interested in finding out the influential factors of choosing of sports in childhood years. It is important to understand the influences, main components and the key players in the process in order to realize high improvement and success. Swimming is one of the most popular and successful sport in Hungary. Our athletes have great accomplishments at the international level. In the last few decades competitors won medals in almost all the Olympic Games, World Championships and European Championships. This is the main reason why we have chosen swimming for the analyses. From the aspect of competitive sport motivations, success, achievement and aims of athletes seem to be the most deciding factors. The primary aim of this research was to identifying the key factors what affect choosing sport of swimmers. **Methodology** We surveyed 424 (N=424) swimmers through questionnaires. Every athlete is a member of a swimming team and takes part in the Hungarian competition system. 214 men (50.4%) and 210 women (49.6%) were questioned. Their average age was 14.42 years, and based on competition results they were placed in two groups. One of them was (Group I.) when swimmers reached minimum 1st-3rd place in Hungarian National Championship and/or 1-16 places in international age-group competition (European Championship, Word Championship). Group II. consisted of swimmers who could not reach this results so were not successful as elite competitors. The data were analysed by SPSS 16.0. **Results** Results show that a relatively high percentage of swimmers begin swimming for health-related reasons. 43,2% of participations began the sport because of health conscious life styles. The impact of success (13,1%) parents (9,6%) and role of peers (6,3%) were low. There were significant differences between the two groups. Swimmers in Group I. ( $2,93 \pm 1,58$ ) started sport activity for competitive sport more than members of Group II ( $2,42 \pm 1,36$ ). Also, men mentioned ( $2,74 \pm 1,45$ ) that competition play more important role in choosing sport than women ( $2,36 \pm 1,40$ ). In choosing swimming the most influenced factor was the own decision (20,7%) and athletes felt that this sport is the better sport for them (26,9%). Success swimmers ( $2,99 \pm 1,51$ ) wanted to take part in swimming more, than non-success ( $2,49 \pm 1,44$ ). **Conclusion** We can conclude, that in choosing sport there are many influential factors. The role of parents and peers in choosing sport activity are less important than health. Athletes began the sport mostly because of health conscious life styles. The own decision was most influential factor in choosing swimming.

## OBJECTIVE MEASUREMENT OF PHYSICAL ACTIVITY IN SCHOOLCHILDREN WITH ACCELEROMETRY AND HEART RATE MONITORING

WEBER, S.1, KOCH, B.1, KOBEL, S.1, BRANDSTETTER, S.1, DREYHAUPT, J.2, WIEDOM, M.2, MUCHE, R.2, STEINACKER, J.M.1

1: SPORTS- AND REHABILITATION-MEDICINE, 2: INSTITUTE OF BIOMETRY AND EPIDEMIOLOGY, ALL ULM UNIVERSITY, GERMANY

**Purpose** International recommendations encourage children to achieve more than 60 min regular physical activity (PA) per day (U.S. Department of Health & Human Services, 2008). Accelerometers provide objective and valid data of PA, particularly in children. The device Actiheart (CamNTEch, Cambridge, UK) measures acceleration (15 sec epochs) in counts per minute (cpm) in combination with heart rate (HR) monitoring in beats per minute (bpm). On the basis of HR classifications it is possible to record the daily activity levels in a quantitative and qualitative manner over a long period of time. The purpose of the study was to determine how much time children spend in moderate and vigorous PA. **Methods** On a total number of 376 children PA was measured. First analyzed data exist of 100 schoolchildren (7.30 $\pm$ 0.54 yrs; male: 53%). Participants wore the Actiheart for six consecutive days, including two weekend days and weekdays in each case. First and last recording days and individual sleeping time were excluded from analysis. Activity levels were categorized as follows: light = HR<140bpm, moderate = HR>140 and <160bpm, vigorous = HR>160bpm (Armstrong & Welsman, 2006). Data were analyzed by a repeated measure ANOVA. **Results** First analyses including all four days (n=72) reveal that children spent 13.1 hours per day (SD 0.77) in light, 36.4 min per day (SD 16.7) in moderate and 18.6 min per day (SD 11.8) in vigorous intensity. PA was significant higher at weekdays vs. weekend days both in moderate (42.2 $\pm$ 22.4 vs. 30.3 $\pm$ 18.4 min per day;  $p=0.001$ ) and vigorous intensities (23.7 $\pm$ 18.0 vs. 13.9 $\pm$ 13.1 min per day;  $p < 0.001$ ). There was no significant difference between boys and girls being moderate active. But boys achieved more time in vigorous intensity (weekdays: 30.3 $\pm$ 19.0 vs. 17.1 $\pm$ 14.3; weekend: 17.0 $\pm$ 14.1 vs. 10.8 $\pm$ 11.4;  $p=0.003$ ). Interaction

between gender and point in time was not significant. Conclusion Consistent with other research (e.g. Riddoch et al, 2007) children spent more time being active during weekdays and boys were more active than girls. In this population PA of 60 min in moderate and vigorous intensity was only achieved for boys at weekdays. References Armstrong, N & Welsman, JR (2006). ### FACTORS AFFECTING PRACTICE OF PHYSICAL ACTIVITY AMONG UNIVERSITY STUDENTS

MORENO GÓMEZ, C., TAULER, P., AGUILÓ, A.

UNIVERSITAT DE LES ILLES BALEARS

**Introduction** Regular physical activity is an important contributor for a healthy lifestyle, having both physical and mental significant health benefits. The aim of the study was to assess the socio-demographic and lifestyle determinants of physical activity in a representative sample of students from the University of the Balearic Islands. **Methods** Cross-sectional study on a sample of 987 students enrolled in university studies. Individuals participated in a survey, which collected information on lifestyles, sports habits and eating habits. A multi-nomial logistic regression analysis was conducted to determine which variables determine the practice of sports among the individuals of the sample. **Results** The sample consisted of 45.5% men (mean age  $21.7 \pm 3.4$ ) and 54.5% women (mean age  $21.3 \pm 3.3$ ). The representation of the different studies in the sample was similar to that of the total enrolled throughout the University. 54.0% of the total sample practiced physical activity regularly. The practice of physical activity was significantly associated to males (OR = 2.68, 95% CI=2.07 to 3.48) with a high quality diet (OR =1.58, 95% CI=1.23 to 2.04), and to be non-smokers (OR =1.64, 95% CI=1.26 to 2.13). These associations remained statistically significant after adjustment for various confounding factors. Physically active men were more likely to have a higher BMI, and to spend fewer hours in front of a computer. Physical activity practice was twice more likely among non-smoker males compared to frequent smokers. Men whose mothers had a high educational level were 3 times more likely to be physically active, compared to men with less educated mothers. An older age and less TV viewing was associated with being physically active among women. **Discussion** Results of the study showed that the practice of sports among students at the University of the Balearic Islands was associated with healthy lifestyles such as no smoking and maintaining a balanced diet. This study proves that the promotion of physical activity in this university will not only improve the physical fitness of students but also will contribute to acquire other healthy lifestyles. We have been able to observe even the different socio-economic factors that influence the practice of physical exercise.

### NATIONAL SPORT POLICIES AND PROMOTION OF HEALTH-ENHANCING PHYSICAL ACTIVITY IN THE EUROPEAN UNION

VESTMARK CHRISTIANSEN, N., MIDDELBEEK, L., KAHLMEIER, S., RACIOPPI, F.

WORLD HEALTH ORGANIZATION, REGIONAL OFFICE FOR EUROPE

**Introduction** National sport policies are an important framework for government action to increase sport and physical activity levels in the population. However, the potential of the sport sector to foster health-enhancing physical activity (HEPA) remains under-utilized. To better understand how the sport sector can contribute to promote physical activity, a joint WHO / European Commission Directorate General for Education and Culture project on promotion of networking, exchange and greater synergy between sport and HEPA sectors was carried out (NET-SPORT-HEALTH). It includes for the first time a systematic collection and content analysis of national sport promotion policies in Europe. **Methods** To identify national sport policies in the EU countries, an already available overview, targeted internet searches and a call to the 27 EU Sport Directors were used. Non-English documents have been translated. The most recent national and subnational sport policies were selected for analysis. A grid covering key indicators was developed for systematic content analysis based on a previous grid for analysing national policy documents on physical activity (Daugbjerg et. al, 2009). **Results** In total 103 national and subnational documents on sport and physical activity resulted from the search. Twenty-six national and subnational sport policies from 15 countries were included into the content analysis and assessed using the analysis grid. The grid includes general items such as year of publication and issuing body as well as target groups addressed, HEPA related items such as specific goals on sport and health, and inclusion of HEPA recommendations. Preliminary observations show that most of the analysed sport policies do formulate overall goals on health; more detailed results will be presented. **Conclusion** The content analysis will be finalized in March 2010. One of the foreseen outcomes is a policy brief with the aim to inform future policy development and support coherence in national strategies to promote HEPA more effectively. **References** Daugbjerg SB, Kahlmeier K, Racioppi F, Martin-Diener E, Martin B, Oja P, Bull, F. (2009). *Journal of Physical Activity and Health*, 6, 805-817.

### AN ECONOMIC ANALYSIS OF EXTRA TIME: A FOOTBALL ORIENTATED COMMUNITY PROGRAMME USING SOCIAL RETURN ON INVESTMENT

TROTTER, L., RICHARDSON, D., PARNELL, D.

THE FOOTBALL FOUNDATION

**AN ECONOMIC ANALYSIS OF EXTRA TIME: A FOOTBALL ORIENTATED COMMUNITY PROGRAMME USING SOCIAL RETURN ON INVESTMENT (SROI)** Trotter, L1., Richardson, D2., and Parnell, D2. 1The Football Foundation (Registered Charity 1079309), Whittington House, 19-30 Alfred Place, London, WC1E 7EA. 2 The Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, UK. **Introduction** Extra Time (ET) is a national programme that aimed to promote positive physical and social opportunities in older people (over 55 years) and tackle social exclusion (Social Exclusion Unit, 2006). ET was delivered by Football in the Community (FitC) schemes across England. The aim of this research is to present the social and economic impacts of the ET programme. **Methods** Social Return on Investment (SROI) is an adjusted cost-benefit analysis that quantifies the value of social, environmental and economic outcomes that result from a service/programme (NEF, 2004). Individual SROI analyses were carried out on five FitC schemes undergoing in-depth study. Stakeholder (i.e., participants and the state) engagement helped identify the outcomes. The 1st Author employed informal and interactional research techniques (including observations, informal interviews and personal reflections). The identified outcomes were measured via the development of entrance and exit participant surveys. 422 participants, 90% over 60 years old, (41% male and 59% female) completed both the entrance and exit surveys (after approximately 8 month's engagement within the ET, Sept 2009–July 2010). Social and economic analysis was conducted employing SROI methodology, using the aforementioned data to provide evidence-based parameter values for use in the calculations. **Results** Results indicate that the measurable social benefits outweigh the investment by more than 1:5.22. Most

value is created for the participant. Authors are keen to tell the story of the complex measures and data involved and not merely focus on the SROI headline. In this sense, the data collected alludes to the development of positive physical, social and emotional changes in the participants, alongside a self reported reduction in use of health services. Discussion This work is vital in building upon the sparse literature available on SROI. The process was extensive, time consuming and expensive. Whilst this provided invaluable context and data, concerns are raised of the 'pressure' of a positive headline, at a cost to 'telling the story' of complex of positive change experienced by participants involved. ##### GLYCOGEN SUPER-COMPENSATION IN THE BRAIN FOLLOWING EXERCISE

MATSUI, T.1,3, ISHIKAWA, T.1, OKAMOTO, M.1,3, ICHITANI, Y.1, KAWANAKA, K.2, SOYA, H.1

1: UNIVERSITY OF TSUKUBA (TSUKUBA, JAPAN), 2: NIIGATA UNIVERSITY OF HEALTH AND WELFARE (NIIGATA, JAPAN), 3: JSPS RESEARCH FELLOW (TOKYO, JAPAN)

**Introduction** The energy source for the brain is not only blood glucose (Glc) but also glycogen (Gly), the Glc storage molecule in the brain (astrocytes), especially when the Glc supply from blood is inadequate (during hypoglycemia) (Brown, 2004). We found that prolonged exhaustive exercise and the resulting hypoglycemia induces a decrease in Gly in five brain loci (the cortex, hippocampus etc.) (Matsui et al., 2011). However, whether Gly is replenished in the brain following exercise is still uncertain. Gly super-compensation in skeletal muscles following exercise with Glc supplementation is well known (Bergstrom & Hultman, 1966). Here we aimed to clarify whether brain Gly would be super-compensated following exercise. **Methods** Rats were separated into three groups: 50% Glc supplementation (+Glc) after exercise, saline supplementation (+Sal) after exercise, and +Glc after sedentary. The rats were exercised on a treadmill running at 20 m/min until exhaustion. The brain was fixed pre-exercise, immediately after exercise, and 3, 6, and 24 hours after exercise by high-power microwave irradiation (MI), which can momentarily inactivate glycogenolysis enzymes. Following MI, samples from the five brain loci (the cortex, hippocampus etc.), skeletal muscles, and the liver were collected to determine Gly levels. **Results** Gly levels in the skeletal muscles were depleted with exercise, and were super-compensated at 24 hours after exercise with +Glc ( $p < 0.01$ ). Gly levels in five brain loci were significantly decreased with exercise, and followed by super-compensated Gly levels at 6 hours after the onset of exercise with +Glc ( $p < 0.05$ ). Furthermore, Gly levels in the cortex and medulla oblongata were super-compensated 3 hours after exercise with +Glc ( $p < 0.05$ ). Additionally, 6 hours after exercise with +Sal, we found that Gly in four brain loci excluding the hypothalamus were super-compensated ( $p < 0.05$ ). On the other hand, 6 hours after sedentary with +Glc, Gly levels in five brain loci were unchanged, although the Gly levels in the skeletal muscles were significantly increased ( $p < 0.01$ ). **Discussion** We found for the first time that Gly super-compensation could also occur in the brain (the cortex, hippocampus etc.) as well as in muscles, but that it appeared earlier than in muscles. Further, in contrast to skeletal muscles, the Gly super-compensation in the brain was not enhanced with Glc supplementation, suggesting a non insulin-dependent mechanism of Gly super-compensation in the brain. Collectively, it is tempting to propose that storage of glycogen in the brain increases with endurance training, and this might be a new target for central fatigue. **References** Bergstrom J, Hultman E. ##### TEN WEEKS OF ENDURANCE OR RESISTANCE TRAINING DOES NOT ALTER DESMIN PROTEIN CONTENT.

FARUP, J., KJØLHEDE, T., SØRENSEN, H., DALGAS, U., VISSING, K.

AARHUS UNIVERSITY

**INTRODUCTION** The cytoskeletal protein desmin is of importance for both the passive muscle stiffness and active force production [1, 2]. The few existing studies on long-term training adaptations of desmin protein content in humans suggest that desmin content increases with resistance [3, 4] but not with endurance training [4]. Furthermore a possible relation between fiber type distribution and desmin content [3, 5] has been proposed. However, the literature is still scarce and in need of further high quality studies on desmin protein content adaptations to long-term training. The purpose of this study was to investigate the effects of ten weeks of either resistance or endurance training on muscle desmin content and fiber type distribution. **METHODS** 14 young, untrained men underwent ten weeks of either lower body resistance (RT,  $n = 7$ ) or endurance cycle (END,  $n = 7$ ) training. Muscle biopsies were harvested from m. vastus lateralis before and after training. Assessment of fiber type area distribution and mean fiber cross-sectional area (CSA) was obtained by ATPase histochemistry, and desmin and actin protein content by immunoblotting [3]. Isometric maximal voluntary contraction (MVC) for knee extensors was obtained in a dynamometer. **RESULTS** ANOVA revealed a tendency for an increase in desmin content ( $p = 0.07$ ), but with no change in actin or desmin to actin ratio in either group following training. Histochemical analysis revealed an overall effect (RT and END pooled) of training for the fiber type area distribution with an increase of Type IIa area % from  $31 \pm 3$  to  $39 \pm 3\%$  ( $p < 0.05$ ) and a tendency towards a decrease of Type IIx area % from  $22 \pm 3$  to  $17 \pm 3\%$  ( $p = 0.069$ ). RT increased mean fiber CSA by  $19 \pm 7\%$  ( $p < 0.05$ ) and MVC by  $19 \pm 5\%$  ( $p < 0.001$ ). **DISCUSSION** The results from immunoblotting revealed no effect of training on desmin content or desmin to actin ratio in either training group unlike previous findings [3, 4]. Fiber type changed similarly in both groups as expected [6], while only RT increased mean fiber CSA. Combining the change in fiber type with the lack of change in desmin protein content contradicts that desmin protein content and fiber type are interrelated as previously suggested [3]. **REFERENCES** 1. ## A SINGLE BOUT OF EXERCISE ACTIVATES SKELETAL MUSCLE SATELLITE CELLS DURING SUBSEQUENT OVERNIGHT RECOVERY

SNIJDERS, T.

MAASTRICHT UNIVERSITY

A single bout of exercise activates skeletal muscle satellite cells during subsequent overnight recovery Snijders, T.I, Verdijk, L.B.I, Beelen, B.I, Kadi, F.2, van Loon, L.J.C.1 1: Department of Human Movement Sciences, NUTRIM School for Nutrition, Toxicology and Metabolism, Maastricht University Medical Centre+, Maastricht, The Netherlands. 2: School of Health and Medical Sciences, Örebro University, Örebro, Sweden. Introduction Skeletal muscle satellite cell content has been reported to increase following a single bout of exercise. Data on muscle fiber type-specific satellite cell (SC) content and/or SC activation status are presently lacking. Therefore the aim of this study was to determine the impact of a single bout of exercise on skeletal muscle fiber type-specific SC content and activation status following subsequent overnight recovery. METHODS Eight healthy males (age:  $20 \pm 1$  yrs; height  $1.77 \pm 0.03$  m; weight:  $65 \pm 2$  kg) performed a single bout of combined endurance and resistance type exercise. Muscle biopsies were collected before and immediately after exercise, and following 9 h of post-exercise, overnight recovery. Muscle fiber type-specific SC and myonuclear content, and SC activation status were determined by immunohistochemical analyses. SC activation status was assessed by immunohistochemical staining for both FA1 and Ki-67. RESULTS Muscle fiber size and fiber area per nucleus were greater in type II compared with type I muscle fibers ( $P < 0.05$ ). At baseline, no differences were observed in the percentage of SC staining positive for FA1 and/or Ki67 between fiber types. No significant changes were observed in SC content following 9 h of post-exercise recovery. However, the percentage of FA1 positive SC increased significantly during overnight recovery, from  $22 \pm 5$  to  $41 \pm 5\%$  and from  $24 \pm 6$  to  $51 \pm 9\%$  in the type I and II muscle fibers, respectively. No changes were observed in the percentage of Ki-67 positive SC (from  $4 \pm 2$  to  $5 \pm 3\%$  and from  $7 \pm 3$  to  $3 \pm 2\%$  for the type I and type II muscle fibers, respectively). DISCUSSION A single bout of exercise activates both type I and II skeletal muscle fiber SC but does not increase SC content during post-exercise overnight recovery.

## SPRINT MODEL DETERMINES THE SKELETAL MUSCLE SIGNALLING RESPONSE TO EXERCISE

PONCE-GONZÁLEZ, J.G., FUENTES, T., GUERRA, B., MORALES-ÁLAMO, D., GUADALUPE-GRAU, A., OLMEDILLAS, H., RODRÍGUEZ-GARCÍA, L., CHAPINAL, E., FEIJOO, D., PÉREZ, I., MARTÍNEZ, P., CALBET, J.A.L.

UNIVERSITY OF LAS PALMAS DE GRAN CANARIA

Sprint exercise leads to the activation of several signalling cascades, particularly those involved in the regulation of metabolism and the response to cellular stress in the skeletal muscle. Although metabolically isokinetic and isotonic sprint exercise are rather similar, the pattern of neural recruitment is likely different and, hence exercise-induced skeletal muscle signalling could also be different. Purpose. To determine if the pattern of muscle recruitment influences skeletal muscle AMPK, MAPK/ERK and STAT3 phosphorylation during sprint exercise on the cycle ergometer (Wingate test). Methods. Fifteen volunteers (ten men and five women) performed a isokinetic 30-s Wingate test and another twelve (seven men and five women) performed a isotonic 30-s Wingate test. Muscle biopsies were taken before, immediately after the exercise and at 30 and 120 minutes during the recovery period. Results. The ACC and p38MAPK phosphorylation responses were similar, whilst the AMPK, STAT3 and ERK phosphorylation responses were significantly different between the isotonic and isokinetic Wingate tests. ACC phosphorylation increased immediately after and 30 min after the isotonic and isokinetic sprint exercise. Compared to pre-exercise values, Thr172-AMPK $\alpha$  and Thy202/Thy204-ERK1/2 phosphorylation was enhanced by about fourfold 30 min after the isotonic sprint ( $P < 0.01$ ), while it remained unchanged 30 min after the isokinetic Wingate. Compared to the value observed right after the end of the exercise, Thy705-STAT3 phosphorylation was increased 30 minutes after the isotonic Wingate test ( $P < 0.01$ ), being the increase 8-fold higher in the isotonic than in the isokinetic sprint ( $P < 0.01$ ). The mean power developed per kg of lower extremities lean mass was linearly related to the 30 min increase in Thy705-STAT3 phosphorylation ( $r = 0.58$ ,  $P < 0.01$ ). Conclusion. Marked increases in AMPK, STAT3, and ERK phosphorylation were observed after a single isotonic 30s all-out sprint (Wingate test) and in ACC phosphorylation after both isotonic and isokinetic 30s all-out sprint (Wingate test) in the musculus vastus lateralis. Only the magnitude of the STAT3 phosphorylation appeared to be determined by the mean power developed during the sprint exercise after accounting for the active muscle mass, indicating that exercise intensity is a main determinant of the STAT3 phosphorylation in response to sprint exercise. Supported by grants from FUNCIS 10/07 and Ministerio de Educación y Ciencia, Spain (DEP2010-21866).

## INCREASED MUSCULAR DEHYDROEPIANDROSTERONE LEVELS ARE ASSOCIATED WITH IMPROVED HYPERGLYCEMIA IN OBESE RATS

SATO, K., IEMITSU, M., AIZAWA, K., MESAKI, N., FUJITA, S.

RITSUMEIKAN UNIVERSITY

Introduction: Dehydroepiandrosterone (DHEA) is most abundantly localized in blood before it is used by target tissues. We reported acute DHEA administration induces improvement of muscular glucose metabolism signaling (Akt/PKC $\zeta$ /GLUT-4) in streptozotocin induced diabetic rats. Exercise training has also been shown effective in restoring glycemic control and reducing insulin resistance in type 2 diabetes. The molecular mechanisms that govern the effects of long-term DHEA administration on muscular glucose metabolism in obesity and hyperglycemia, however, are still unclear. Purpose: The purpose of this study was to assess the effects of DHEA administration and exercise training on muscular DHEA and 5 $\alpha$ -dehydrotestosterone (DHT) levels and hyperglycemia in diet-induced obese and hyperglycemic rats. Methods: After 14 weeks of a high-sucrose diet, obese male Wistar rats were assigned randomly to one of three 6-week regimens: control, obese DHEA treatment or obese exercise training (running at 25 m/min for 1 hour, 5 days/week) ( $n = 10$  each group). Results: The results indicate that either 6 weeks of DHEA treatment or exercise training significantly attenuated serum insulin and fasting glucose levels compared with the control group. Plasma and muscle concentrations of DHEA and DHT, and expression levels of 5 $\alpha$ -reductase were significantly higher in the obese DHEA-treated and exercise-training groups. Moreover, both DHEA administration and exercise training upregulated GLUT4 translocation with concomitant increases in protein kinase B and protein kinase C- $\zeta$ / $\lambda$  phosphorylation. Muscle DHEA and DHT concentrations closely correlated with blood glucose levels (DHEA treatment:  $r = -0.68$ ,  $P < 0.001$ ; exercise training:  $r = -0.65$ ,  $P < 0.001$ ), serum insulin levels, and activation of the GLUT4-regulated signaling pathway. Conclusion: Thus, it is speculated that increased levels of muscle sex steroids may contribute to improved fasting glucose levels via upregulation of GLUT4-regulated signaling in diet-induced obesity and hyperglycemia.

## THE INTERACTIVE EFFECTS OF EXERCISE TYPE AND AMBIENT TEMPERATURE ON HSP72 IN ACTIVE FEMALES

HOSSEINZADEH, M., ABDI HAMZEHKOLAEI, H., DABIDI-ROSHAN, V.

UNI. OF MAZANDARAN

**Introduction** Skeletal muscle adapts to the stress of contractile activity via changes in gene expression to yield an increased content of a family of highly conserved cytoprotective proteins known as heat shock proteins (HSPs) (Smuder et al. 2011). We aimed to determine the interactive effects of endurance or weight training in the normal or moderate heat environments on HSP72, the major heat shock protein's response in active young females. **Methods** Forty-five female students were randomly assigned to five groups; endurance training+normal heat (ET+NH), endurance training+moderate heat (ET+MH), weight training+normal heat (WT+NH), weight training+moderate heat (WT+MH) and heat group (HG). The training protocols included running to exhaustion on treadmill at %65-75 V02max in ET groups and 4 sets of eccentric actions of elbow flexors in WT groups in the normal and moderate heat environments. The heat group (HG) only exposed to heat. A sandwich ELISA, enzymatic assay and ELISA were used for determination of HSP72, CK and cortisol values respectively. **Results** The ET and WT, in the moderate heat ambient resulted in an increase in the HSP72, CK and cortisol values, as compared to ET+NH and WT+NH groups and the baseline. The HG group did not demonstrate any considerable changes in these parameters. **Discussion** This research is the first time studying interactive effects of exercise type (concentric vs. eccentric) and ambient temperature (moderate vs. normal) on HSP72 changes in active young females. The data showed endurance and weight training, particularly, in the moderate heat ambient increase the serum HSP72, CK and cortisol values. Furthermore, the HSP72 and CK concentrations significantly increased in the WT+NH group. In summary, exercise training, particularly, training in moderate ambient increased serum HSP72 in the young active females and its magnitude was related to the type of exercise and environment heat. These findings support the theory that the eccentric exercise and exercise-induced body temperature (not passive heating) may be the reason for further increase in HSP72 levels compared to non-damaging exercise such as endurance training (Yamada et al. 2008, Murlasits et al. 2006). Although in this study the last sampling of subjects was done 30 min after the endurance or weight training, we suggest using multiple post exercise sampling in future studies. **References** Smuder AJ, Kavazis AN, Min K, Powers SK. ## EFFECTS OF ENDURANCE TRAINING AND IMMOBILIZATION ON INTRACELLULAR OXYGEN DYNAMICS DURING MUSCLE CONTRACTION

TAKAKURA, H.1, YAMADA, T.1, FURUICHI, Y.1, OJINO, M.1, IWASE, S.2, JUE, T.3, MASUDA, K.1

1: KANAZAWA UNIV. (JAPAN), 2: AICHI MEDICAL UNIV. (JAPAN), 3: UNIV. OF CALIFORNIA DAVIS (USA)

**Introduction** Myoglobin (Mb) desaturates without time delay during muscle contraction, reflecting rapid decrease in the intracellular oxygen (O<sub>2</sub>) tension of Mb (PmbO<sub>2</sub>), which expands the O<sub>2</sub> gradient to increase the O<sub>2</sub> flux in order to meet the increased energy demands (Takakura et al., 2010). However, the effects of endurance training (eTR) and immobilization (IM) on intracellular O<sub>2</sub> dynamics during muscle contraction are unknown. Therefore, the present study investigates the effects of eTR and IM on the dynamics of Mb saturation (SmbO<sub>2</sub>) and PmbO<sub>2</sub> in contracting muscles, using a hindlimb perfusion model. **Methods** Male Wistar rats were randomized into the eTR, IM, or Control (Con) group. Rats in the eTR group underwent a 4-week swimming eTR (6 days/week, 30 min × 4 sets/day) with a weight of 2% body mass. IM group rats had their left hindlimbs immobilized at the full plantar flexion using a thermoplastic cast for 3 weeks. After the eTR or IM periods, the muscle tension and muscle oxygen consumption (mVO<sub>2</sub>) in the gastrocnemius-soleus-plantaris (GPS) muscle were measured under hemoglobin-free medium perfusion. During muscle contraction, the deoxygenated Mb signal was monitored by near-infrared spectroscopy. SmbO<sub>2</sub> at the steady state, calculated by quantified Mb deoxygenation kinetics, was converted into PmbO<sub>2</sub> and the release rate of O<sub>2</sub> from Mb was calculated by multiplying Mb deoxygenation rate as a percentage per second and Mb concentration (IMb). Citrate synthase (CS) activity, [IMb], ATP concentration, and lactate to pyruvate ratio (L/P) in the venous effluents were measured spectrophotometrically. **Results** After eTR, the maximal muscle tension, mVO<sub>2peak</sub>, [IMb], and CS activity increased, whereas L/P decreased. The increase in the release rate of O<sub>2</sub> from Mb after eTR accelerated the rate increase in ΔmVO<sub>2</sub>. eTR shifted the ΔmVO<sub>2</sub>-PmbO<sub>2</sub> curve upward regardless of the increase in ΔmVO<sub>2</sub>. CS activity, [IMb], and L/P were unaffected by IM, but GPS muscle mass, maximal muscle tension, and ATP resynthesis efficiency decreased, and the mVO<sub>2peak</sub> and ΔmVO<sub>2</sub> at the same absolute tension increased. The release rate of O<sub>2</sub> from Mb at the maximal twitch tension and the same oxygen demand was attenuated after IM. IM shifted the ΔmVO<sub>2</sub>-PmbO<sub>2</sub> curve upward. **Discussion** Although PmbO<sub>2</sub> was not likely to be involved in the increase in ΔmVO<sub>2</sub> after eTR and IM, the release rate of O<sub>2</sub> from Mb fluctuated in accordance with the level of physical activity, which might be associated with altered mitochondrial respiration rate at the onset of the muscle contraction. **References** Takakura H, Masuda K, Hashimoto T, Iwase S, Jue T. (2010). *Exp Physiol*, 95, 630-640.

## ALBUMIN, A LIPID TRANSPORTER OR A WEIGHT LOSS STRATEGY?

SAKAMOTO, M., CAPERUTO, E.C.

MACKENZIE PRESBITERIAN UNIVERSITY

**Introduction:** Lipid deriving energy from the adipocytes has some steps before it turns completely into energy. (JEUKENDRUP et al., 1998). FFA bond to albumin to be transported to the muscle where it will be burned. **Objective:** Our study had the objective to investigate the effects of acute albumin supplementation on body composition and its relation with lipid transport and utilization. **Methods:** We had 5 male subjects with 21.8 ± 2.17 years old in two different days. On the first day (Albumin group), subjects ingested 20g of albumin in 250mL of water after a 4hour fast, 60 minutes before the test. On the second day (Control group) we had the same protocol but subjects ingested whey protein. Test consisted of 1hour of running at 65% of max FC (Karvonen et al, 1957) with compulsory ingestion of 500mL of water during the test. We evaluated weight, skinfold (Jackson & Pollock, 1978) and circumferences (before and after the test) we also measured blood lactate and glucose on rest, 20, 40 and 60 minutes within the test. **Results:** Albumin group had an average weight of 77.14 ± 5.32 (pre test) and 76.4 ± 5.03 (post test), Control group had 77.04 ± 5.0 (pre test) and 76.68 ± 5.02 (post test), sum of skinfold from Albumin group was 88.80 ± 2.22 (pre test) and 83.86 ± 2.39 (post test) and Control group had 99.52 ± 2.92 (pre test) and 93.05 ± 2.63 (post test), all these reductions had p<0.05 level of significance. Body fat percentage from Albumin group was 11.65 ± 2.96 (pre test) and 10.82 ± 2.85 (post test), with a significant reduction (p<0.05) when compared to Control group 14.42 ± 7.42 (pre test) and 12.34 ± 3.96 (post

test). Discussion/Conclusion: The circumferences studied decreased significantly only on the abdomen. The glucose and lactate profile observed suggested greater involvement of lipids as the predominant energy substrate, especially at the end of the test, according to the literature. Thus, we conclude that albumin group showed significant fat loss, evidencing the effects of acute albumin supplementation on reducing body fat when combined with moderate exercise. ## EFFECTS OF DIET AND AEROBIC EXERCISE ON LIPOPROTEINS, BASAL METABOLIC RATE AND ACYLATED GHRELIN IN GRADE 1 OBESITY

OLIVEIRA, A.R.1, LOPES, A.L.1, CAMPOS, L.3, FAYH, A.P.2, CUNHA, G.S.1, TEIXEIRA, B.1, SILVA, D.P.1, RIBEIRO, J.L.3, FRIEDMAN, R.2

1 – ESEF - UFRGS, PORTO ALEGRE, BRAZIL; 2 – HCPA – UFRGS, PORTO ALEGRE, BRAZIL; 3 – IPA METHODIST, PORTO ALEGRE - RS, BRAZIL

**Introduction** A number of strategies have been tested to determine the best approach in order to prevent and control obesity. The reduction of 5% to 10% of body weight through diet and exercise is suggested as effective for health improvement. Lipoproteins (LP), Basal Metabolic Rate (BMR) and Acylated Ghrelin (AG) are important markers to monitor this population, since they keeps relationship with vascular health, energy expenditure and appetite, respectively. **Methods** In order to investigate the effects of diet and physical exercise on BMR, Lipid profile and AG, 18 subjects (20 to 40 years, BMI 30kg.m<sup>-2</sup>) were randomly allocated in two groups, Diet (DG) or Diet plus Aerobic Exercise (D+EG). Blood samples were taken before and after a 5% reduction in body mass to evaluate the levels of acylated ghrelin, cholesterol and glucose. BMR was evaluated through gas analysis in an automated metabolic cart. A two way ANOVA and a Bonferroni Test were carried out. The study was approved by the local Ethics in Research Committee. **Results** The D+EG got a 5% loss in body mass faster than DG (74.1±26 vs. 85.1±26.5 days). After the weight loss, DG reduced total cholesterol (194.2±28.51 vs. 174±45.8 mg.dl<sup>-1</sup>), LDL cholesterol (107.2±20.2 vs. 88.85±9.2 mg.dl<sup>-1</sup>) and Fat-Free Mass (61.4 ±10.0 vs. 59.3 ± 9.2 kg). By contrast, D+EG has a significantly decrease in AG (54.4±35.3 vs. 33.2±29.1 pg.ml<sup>-1</sup>), and increased BMR (1363±379 vs. 1633± 223 kcal.day<sup>-1</sup>). **Discussion** The results were intervention dependent. The reductions in total cholesterol and LDL in GD are possibly justified by a reduction of fats and an increase in fibres in the diet composition (Nieman et al., 2002). Furthermore, the FFM reduction was due to lack of muscle stimulation and catabolic effect of diet on the tissue (Bielinski et al., 1985). The D+EG showed an AG reduction and a BMR increase. The AG reduction may be related to the type (aerobic) and the intensity (70% VO<sub>2</sub>max) of exercise (Broom et al., 2007). Moreover, the BMR increased thanks to the maintenance of fat-free mass promoted by exercise (Bielinski et al., 1985). In summary, the DG seems to induce an improvement on the lipid profile whereas D+EG induces a decrease on AG. It seems to be related to appetite regulation. Such differences can be associated with differences in the total intervention time. **References** Nieman, DC, Brock, DW; Butterworth, D. J. *Am Coll. Nutr.* v. 21, p. 344-350, 2002. ## ANABOLIC STEROID USE AND CARDIAC MORPHOLOGY AND FUNCTION: NOVEL INSIGHTS FROM MRI AND SPECKLE TRACKING

ANGELL, P., WHYTE, G., GREEN, D., PRASAD, S., TEVFIK, I., WAGE, R., GEORGE, K.

LIVERPOOL JOHN MOORE'S UNIVERSITY

The prevalence of anabolic steroid (AS) use has increased in recent years. Whilst case studies of arrhythmia and myocardial infarction in AS users are common, the cardiovascular (CV) health consequences of AS abuse remain controversial. Previous case-control data in AS users have largely failed to document a consistent risk or arrhythmic substrate in AS users. MRI represents a gold-standard technique for cardiac structure and function and gadolinium enhancement of MRI allows detection of interstitial fibrosis. Both approaches have not been used previously in AS users. We hypothesise there will be a significant effect of AS use on systolic and diastolic cardiac function as well as a reduced strain (ε) and strain rate (SR) in AS users at a regional and global cardiac level. Regular resistance training individuals who self-reported a minimum of 2 years of AS use (n=6) or who had never used AS (NAS, n=7) underwent CV assessment. Cardiac MRI assessed maximum left ventricular (LV) wall thickness (WT), LV mass (LVM), LV and right ventricular (RV) ejection fraction (EF) as well as the presence of fibrosis. Speckle tracking echocardiography assessed ε and SR in 3 planes of cardiac motion. Blood pressure, resting heart rate (HR) were recorded as well as standard lipid profiles. Data was analysed using independent T-Tests or Mann-Whitney U-tests. All data given as mean±SD except E:A values which are presented as median. Resting HR (AS: 82±6 v NAS: 65±14 b.min<sup>-1</sup>), LVM (AS: 202±28 v NAS: 170± 21 g) and peak LVWT (AS: 11.3±1.0 v NAS: 9.7±1.0 mm) were significantly increased in AS. There was no significant difference in LVEF (AS: 62±3 v NAS: 63±4%) whilst RVEF was significantly reduced in the AS (AS: 53±31 v NAS:59±5%). There was no evidence of interstitial cardiac fibrosis. In AS users the early:atrial (E:A) peak diastolic flow velocity filling ratio (AS: 1.48 v NAS: 1.91) and early:atrial peak tissue (E':A') velocity filling ratio (AS: 1.26 v NAS: 1.87) were significantly reduced. Longitudinal peak ε (AS: -12.8±1.7 v NAS: -16.3±1.8%), systolic (AS:-0.83±0.13 v NAS:-1.15±0.12 .s<sup>-1</sup>) and E SR (AS: 1.17±0.22 v NAS:1.67±0.30 .s<sup>-1</sup>) were significantly decreased in the AS group. Apical peak rotation (AS: 2.57±5.63 v NAS: 8.60±4.27o) was significantly decreased in AS. A significant reduction in high-density lipoprotein (HDL) and an increase in triglycerides and total cholesterol: HDL ratio was seen in AS users (p<0.05). Using gold standard MRI techniques and speckle tracking echocardiography, this study reported that AS users have significant LV hypertrophy and reduced LV and RV function that may precipitate an increased risk of arrhythmia or cardiac event. A lack of interstitial cardiac fibrosis would suggest risk of arrhythmia is not further augmented.

**PLASMA OXIDIZED LDL CONCENTRATION INCREASES IN STRENGTH-TRAINED MEN**

CHOI, Y., MAEDA, S., YOSHIZAWA, M., TANABE, K., MIYAKI, A., TANABE, Y., KOMINE, H., HIRAYAMA, A., SHIRAKI, H., AJISAKA, R.

UNIVERSITY OF TSUKUBA

Background: Oxidative stress, the imbalance in oxidants and antioxidants, may play an important role in the development of major health-related events such as mobility limitation, disability, and mortality. Oxidized low-density lipoprotein (oxLDL) has been shown to play a major role in the progression of atherosclerosis and cardiovascular disease. Aerobic exercise training has been reported to decrease plasma oxLDL levels. There are no studies, however, regarding the effect of strength exercise training on plasma oxLDL levels. The purpose of this study was to investigate the plasma oxLDL concentration and antioxidant capacity in plasma in strength-trained men. We specifically assessed the total scavenging activity against plasma hydroxyl radical (HO•) and alkoxyl radical (RO•) by using the electron spin resonance (ESR) with spin-trapping, because both radicals are involved in oxLDL production. Methods: The subjects included young strength-trained men (SA group; shot put, hammer, javelin throwers, or power lifters; n = 9), and sedentary individuals (control group; n = 9). We measured plasma oxLDL concentrations and total scavenging activity against HO• and RO•. Results: Maximal muscle strength, assessed by isokinetic tests of the knee and elbow joints and maximal handgrip strength, was significantly greater in the SA group than in the control group. Plasma oxLDL concentrations were found to be significantly higher in the SA group than in the control group. The total scavenging activity against HO• and RO• in plasma did not differ between the 2 groups. Conclusion: The present study showed that the plasma oxLDL concentrations were significantly higher in strength-trained men than in sedentary individuals. We also showed that the total scavenging activity against HO• and RO• in plasma did not differ between the strength-trained men and sedentary individuals. These findings suggest that high-intensity strength exercise training increases plasma oxLDL concentrations without upregulating the scavenging activity against plasma HO• and RO•. **CARDIORESPIRATORY FITNESS OR BODY COMPOSITION: WHICH FACTORS INFLUENCES CARDIAC MORPHOLOGY?**

CARTER, H.H.1, SPENCE, A.1, BUCK, C.1, NAYLOR, L.H.1, DEMBO, L.2, GEORGE, K.3, GREEN, D.J.1,3

1: UWA (AUSTRALIA) 2: RPH (AUSTRALIA) 3: RISES (LIVERPOOL)

Background: Athletic training is associated with changes in left ventricular morphology, a phenomenon known as 'athlete's heart'. However, heart size also varies with body size and composition, making training-induced differences between subjects difficult to interpret. In the past, body surface area, body mass index and height have been widely used in the clinical domain as indices to scale for heart size. However, assessment of the importance of different scaling factors has been limited by the use of echocardiography and indirect or gross methods of body composition analysis. We therefore assessed relationships between body composition, cardiorespiratory fitness levels (CRF) and left ventricular cardiac morphology using dual-energy X-ray absorptiometry (DXA) and cardiac MRI. Methods: Twenty five recreationally active males (27±5 years) were recruited and underwent assessments of cardiac morphology, CRF levels and body composition. CRF was assessed using a maximal aerobic capacity (VO2peak) treadmill exercise test while cardiac morphology was assessed using cardiac MRI. Body composition was measured using DXA. Bivariate correlations were performed between all variables and a backwards stepwise regression model was used to independently assess the relationships between regional components of body composition and left ventricular morphology. Results: Left ventricular mass (LVM) was significantly correlated with VO2peak ( $r=0.735$ ,  $p<0.001$ ), lean body mass (LBM) ( $r=0.832$ ,  $p<0.001$ ) and fat mass ( $r=0.469$ ,  $p<0.02$ ). Backwards stepwise regression analysis involving the regional mass components of LBM and fat mass revealed LBM of the legs ( $t=5.58$ ,  $p<0.001$ ), fat mass of the trunk ( $t=4.65$ ,  $p<0.001$ ), legs ( $t=-3.2$ ,  $p<0.005$ ) and android ( $t=-4.11$ ,  $p<0.002$ ) were the strongest predictors of LVM. Conclusion: This study used MRI and DXA technology to address the question of appropriate cardiac scaling for CRF and body composition. CRF was strongly correlated with LVM however this relationship failed to be significant once VO2peak scores were normalised for body weight. Highly significant associations were evident between LVM and LBM, particularly of the lower limbs. LBM predominantly consists of skeletal muscle, a highly metabolic active tissue. A physiological explanation for the relationship between LBM and LVM may relate to haemodynamic stress associated with skeletal muscle activation during exercise. LBM of the legs may be a more appropriate scaling variable for cardiac morphology than other variables such as body surface area and height, which are widely used clinically.

**CLUSTERED CARDIOMETABOLIC RISK, CARDIORESPIRATORY FITNESS AND PHYSICAL ACTIVITY IN 10-11 YEAR OLD CHILDREN. THE CHANGE! PROJECT.**

GOBBI, R.1,2, DAVIES, I.G.2, FAIRCLOUGH, S.J.1,2, HACKETT, A.F.1,2, MACKINTOSH, K.A.1,2, WARBURTON, G.L.1,2, STRATTON, G.1,3, GEORGE, K.P.3, BODDY, L.M.1,2,3

LIVERPOOL JOHN MOORES UNIVERSITY

Introduction: Evidence suggests that insufficient levels of physical activity (PA) and cardiorespiratory fitness (CRF) are associated with cardiometabolic risk (Andersen et al 2008). This study aims to investigate the relationship between CRF, PA and clustered cardiometabolic risk in children, employing both traditional, (e.g. Total Cholesterol [TC]) and emerging non invasive (e.g. LV Mass Index), risk markers. Methods: Participants (n=60) were recruited from 12 primary schools (mean age = 10.6 (±0.3) years) in Wigan. Habitual PA was measured using 7 day accelerometry and CRF by VO2peak. Assessments of body composition (DEXA), cardiovascular structure (LV Mass Index) and function (blood pressure) were completed. Fasting capillary blood samples were taken and analysed for TC, High Density Lipoprotein Cholesterol (HDL-C) and glucose. Twenty-eight participants had valid data for all components of the clustered risk score, calculated using TC:HDL-C, glucose, systolic BP, LV Mass Index, and trunk fat mass (g). Participants with a clustered risk score greater than 1SD above the mean, were categorised as 'high' risk (n=5); all others were categorised as 'normal' risk. ANCOVA, with somatic maturity and gender as covariates, was used to determine differences in VO2peak; Total PA; moderate to vigorous PA (MVPA), and vigorous PA (VPA) between risk groups. Pearson's correlation coefficients, controlling for gender and maturation, were completed to assess the relationship between clustered risk score and VO2peak, Total PA, MVPA, and VPA. Results: Those in the 'normal' risk group were more fit than those in the 'high' risk group (mean 'normal' 43.8 ± 8.6 vs. mean 'high' 35.1 ± 8.9 ml/kg/min ( $t(1,24)=4.518$ ,  $p=0.044$ )). Those in the 'normal' risk group accrued more VPA than the 'high' risk group (mean 'normal' VPA= 16.0 ± 8 vs. mean 'high' VPA=11.7 ± 4.9 mins/day,  $p>0.05$ ). Furthermore, clustered risk score correlated with VPA ( $r=-0.413$ ,  $p=0.045$ ) and VO2peak ( $r=-0.514$ ,  $p=0.007$ ). Total PA and MVPA did not correlate significantly with clustered risk. Discussion: Cardiometabolic risk is negatively associated with VPA and CRF. This study advances knowledge with further evidence of the importance of promoting CRF and PA, for cardiometabolic risk reduction, combining traditional risk

markers with non invasive emerging measures. Furthermore, this study emphasises the importance of promoting VPA in children. Reference: Andersen, L. B., Sardinha, L. B., Froberg, K., Riddoch, C. J., Page, A. S. & Andersen, S. A. (2008). *Int J Pediatr Obes*, 3, 58-66.

### CARDIOVASCULAR RESPONSES TO A LOW VOLUME HIGH INTENSITY EXERCISE INTERVENTION IN MIDDLE AGED ADULTS

MAIR, J.1, DE VITO, G.1,2, DITROILO, M.1, MCKEOWN, D.2, COLEMAN, S.1,2, LOWERY, M.1, CAULFIELD, B.1,2, BOREHAM, C.1  
1. UNIVERSITY COLLEGE DUBLIN, (DUBLIN, IRELAND) 2. TRIL CENTRE (DUBLIN, IRELAND)

**Introduction:** Recent research (Gibala & McGee 2008) has demonstrated that high intensity interval training (HIT) stimulates physiological adaptations similar to those observed following a traditional endurance training programme, despite a greatly reduced total exercise volume. Although these results show promise in improving health and fitness, the sprint training involved demands a high level of motivation and responses have only been examined in young adults. The aim of the present study, therefore, was to investigate the cardiovascular response to a 4 week progressive step exercise training protocol in a middle-aged population. Stepping is a high-intensity activity that can be carried out in a controlled manner in an indoor setting and is therefore a variant of HIT that may be more suited to older populations. We hypothesised that cardiovascular fitness would be improved following 4 weeks of step training compared with a 4 week control period of no exercise. **Methods:** Thirty three sedentary healthy middle aged adults (age: 59.8, 2.71yrs (mean, SD), height: 167.2, 7.53, weight: 74.3, 13.63kg) took part in the step exercise training programme. Starting at baseline (PRE), participants acted as their own controls over a 4 week period (CTL) immediately preceding the intervention. They then accumulated up to 9 minutes of exercise per day on 3 days of the week over the 4 weeks experimental period. Step height and cadence were individually prescribed using a linear regression prediction model, producing a target intensity of 80% of heart rate reserve (HRR). Measures of VO<sub>2</sub>, HR and RPE were obtained during an incremental step test whereby step height remained constant and cadence was increased every 2 minutes until HR reached 85% of predicted maximum. This was repeated on 3 occasions: PRE, CTL and POST (following the 4 week training period) and ANOVA with repeated measures was used to detect differences in the dependent variables. **Results:** No differences were found between PRE and CTL for any measured variable ( $p>0.05$ ). The main effects for training (PRE vs POST) were statistically significant as decreases were observed in VO<sub>2</sub>, HR & RPE ( $p=0.001$ ) at a given sub-maximal intensity. **Discussion:** These results show that accumulated bouts of stepping exercise equivalent to only 21 minutes per week over a 4 week period are sufficient to improve cardiovascular fitness in sedentary middle-aged participants. Thus, stepping is a variant of HIT that appears effective, safe and well tolerated by a middle aged population, and could be well suited to public health initiatives based on exercise prescription for older populations. **References:** GIBALA MJ & MCGEE SL (2008) *Exerc Sport Sci Rev*, 36 (2), 58-63

### THE ACUTE EFFECT OF ISCHEMIC PRECONDITIONING ON REPEATED HIGH-INTENSITY EXERCISE PERFORMANCE OF ELITE RUGBY PLAYERS

BAILEY, T., ATKINSON, P., ATKINSON, G., JONES, H., DRAWER, S., THIJSEN, D.H.J.  
LIVERPOOL JOHN MOORES UNIVERSITY

**THE ACUTE EFFECT OF ISCHEMIC PRECONDITIONING ON REPEATED HIGH-INTENSITY EXERCISE PERFORMANCE OF ELITE RUGBY PLAYERS** Bailey, T.1,2, Atkinson, P.3, Atkinson, G. 1, Jones, H. 1, Drawer, S. 4, Thijssen, D.H.J. 1, 5. 1 RISES, LJMU, 2 S&PA, Edge Hill University, 3 EIS, Bisham Abbey, 4 UK SPORT, UK, 5 Dept. of Physiology, Radboud University, Netherlands. **Introduction** Previous animal studies have shown that repeated bouts of ischemia followed by reperfusion, known as ischemic preconditioning (IPC), leads to beneficial vascular and muscular adaptations. Interestingly, recent data in humans found that IPC improves exercise performance during an aerobic exercise test in moderately and well-trained individuals. To date, no research has examined the potential effect of IPC on high-intensity (HI) exercise performance in humans and we hypothesised that IPC would improve workload and attenuate fatigue during HI performance. The aim was to establish the effects of IPC on HI running and cycling performance in elite rugby players. **Methods** In a randomised, single-blind, crossover study, 13 elite male rugby players performed two different sprint protocols, which were preceded by IPC or a control (C). On 2 subsequent days, subjects performed an indoor, running Repeated Anaerobic Sprint Test (RAST). Then 6 days later, performed a repeated sprint test on a stationary ergometer (10 cycles of 15s sprint – 30s active recovery, 60rpm) on 2 subsequent days. IPC involved 4 series of 5 min ischemia (~170 mmHg) on alternate legs, followed by a standard warm-up. C consisted of 40 min seated rest. The order of IPC and C between the 2 tests was randomised between- and within-subjects. From the RAST, we calculated sprint time, power-output and fatigue index, whilst heart rate, total work, peak and mean power-output were measured during the ergometer tests. Data were analysed using a repeated measures ANOVA, with 95% confidence intervals (CI). **Results** Power declined during both RAST in all subjects ( $P<0.05$ ), but did not differ significantly between IPC and C. IPC tended to improve peak power (IPC:  $1278\pm150$  vs. C:  $1269\pm140$  W), fatigue index (IPC:  $54\pm5$  vs. C:  $52\pm4$  %) and mean power (IPC:  $659\pm54$  vs. C:  $653\pm53$  W). The upper limit of the 95%CI favoured a beneficial effect on performance (Mean power: 95%CI -8.2 to 18.4W; Fatigue Index: 95%CI -1.8 to 4.8%). A significant familiarisation effect was observed during the cycling test, with a significantly higher work produced on day 2 (Day 1:  $6509\pm574$ , Day 2:  $6626\pm493$  W;  $P<0.05$ ). **Conclusion** This is the first study to examine the performance effects of IPC in elite athletes. Our data suggest IPC potentially enhances power in HI exercise in elite rugby players. However, future laboratory-based studies, that include familiarisation and improve precision of estimates of change, are necessary to provide further insight into the potential impact of IPC for HI performance in elite athletes. **References** De Groot. et al. (2010). *EJAP*, 108, 141

### PREVALENCE OF RISK FACTORS FOR CARDIOVASCULAR DISEASE AND DIABETES IN CHILDREN AGED 11-13: A SCHOOL BASED CROSS-SECTIONAL STUDY.

REES, A.  
UNIVERSITY OF WALES INSTITUTE CARDIFF

**Objective:** Risk factors for cardiovascular disease (CVD) and Type 2 diabetes (T2DM) originate during childhood. This study examines the prevalence of risk factors for CVD and T2DM in children aged 11-13 years and investigates factors associated with high risk of these diseases. **Methods:** Data from 10 schools from South Wales were used. 1147 children (490 male: 657 female) took part. A high risk child was one with 2 or more of the following features; overweight or obese, waist circumference >90th centile for age and sex, high blood pressure, high cholesterol, high fasting glucose, unfit or high percentage of body fat. Logistic regression was used to analyse the data. **Results:** A third of children were overweight and 42% were classed as unfit. Children in deprived schools were 1.8 times more likely to have high blood pressure compared to those in non-deprived schools (15% compared to 8%, respectively). Adjusted logistic regression analysis

sis revealed that having overweight parents, living in a deprived area, low self reported activity levels and a high birth weight, were factors that were independently associated with a child being at a high risk (i.e. two or more risk factors). Conclusions: This study presents data from a wide spectrum of schools across South Wales. The high number of children with risk factors for CVD and T2DM suggests future interventions will need to focus on community and change rather than targeting high risk individuals' behaviour.

### THE IMPACT OF EXERCISE INTENSITY UPON LEFT VENTRICULAR FUNCTION AND CARDIAC TROPONIN I DURING RECOVERY

CHAN-DEWAR, F., GREGSON, W., WHYTE, G., KING, J., GAZE, D., CARRANZA-GARCÍA, L., LEGAZ-ARRESE, A., GEORGE, K.

LIVERPOOL JOHN MOORES UNIVERSITY

The impact of exercise intensity upon left ventricular function and cardiac troponin I during recovery Chan-Dewar F.1, Gregson W.1, Whyte G.1, King J.1, Gaze D.2, Carranza-García L.3, Legaz-Arrese A.4 and George K.1 1: LJMU (Liverpool, UK), 2: St George's Healthcare NHS Trust (London, UK), 3: UANL (Nuevo Leon, Mexico), 4: University of Zaragoza (Zaragoza, Spain) Introduction Multiple reports provide evidence of a transient depression in left ventricular (LV) global and regional myocardial function, and a delay between the electrical activation and peak tissue velocity post-exercise (Neilan et al. 2006; Chan-Dewar et al. 2010). Release of cardiac troponin I (cTnI) also has been observed in many prolonged exercise settings. Exercise intensity might alter the nature and magnitude of cardiac function, cardiac electro-mechanical delay (cEMD) and cTnI appearance during recovery. Therefore the study focuses of assessing LV functional changes before and after two bouts of cycling at different intensities. Methods Twelve healthy male recreational cyclists (age:  $34 \pm 9$  years) performed two 40 km cycling time-trials at high (H) and moderate (M) intensities (80-95% and 60-75% of maximal heart rate) in a controlled environment. Echocardiograms were recorded digitally pre/post exercise and analysed off-line. Blood samples were collected at the same time. Analysis was by two-way ANOVA. Results Global LV diastolic function was reduced after both cycle bouts (Doppler peak early diastolic flow velocity E, H:  $0.71 \pm 0.12$  vs.  $0.63 \pm 0.09$  m.s<sup>-1</sup>; M:  $0.73 \pm 0.12$  vs.  $0.66 \pm 0.13$  m.s<sup>-1</sup>,  $P < 0.05$ ; peak early diastolic tissue-Doppler myocardial velocity E', H:  $0.14 \pm 0.04$  vs.  $0.12 \pm 0.03$  m.s<sup>-1</sup>; M:  $0.12 \pm 0.03$  vs.  $0.11 \pm 0.02$  m.s<sup>-1</sup>,  $P < 0.05$ ). Evidence of an extended cEMD after cycling was present from QRS onset to peak S' (H:  $174 \pm 52$  vs.  $198 \pm 26$  ms; M:  $151 \pm 40$  vs.  $178 \pm 52$  ms,  $P < 0.05$ ) and peak E' (H:  $524 \pm 95$  vs.  $664 \pm 68$  ms; M:  $495 \pm 62$  vs.  $604 \pm 91$  ms,  $P < 0.05$ ). Global LV systolic function was not altered with sporadic evidence of regional changes (basal longitudinal strain, H:  $-19.6 \pm 3.1$  vs.  $-16.6 \pm 3.9\%$ ; M:  $-18.7 \pm 2.5$  vs.  $-15.3 \pm 2.3\%$ ,  $P < 0.05$ ). cTnI was elevated in two participants after High-trial (0.06 ug.L<sup>-1</sup>; 0.04 ug.L<sup>-1</sup>) and one participant after M-trial (0.02 ug.L<sup>-1</sup>). Discussion The decline in LV diastolic function is consistent with the past work, and is seemingly independent of exercise duration/volume. An increase in time-delay suggests that some mechanism intrinsic to myocardial relaxation is involved. There were no noticeable differences in LV function or cTnI appearance during recovery after the two bouts of different intensity cycling. References Neilan T, Januzzi J, Lee-Lewandrowski E et al. (2006). Circulation. 114:2325-2333. Chan-Dewar F, Oxborough D, Shave R et al. (2010). Eur J Appl Physiol. 108:581-587.

### IS CARDIAC REHABILITATION EFFECTIVE AT MAINTAINING HEALTHY LIFESTYLES?

DUNN, S.1, LARK, S.2, FALLOWS, S.1

\*UNIVERSITY OF CHESTER, UK; †MASSEY UNIVERSITY, NZ

Introduction Secondary Preventive Cardiac Rehabilitation (CR) programmes are cost effective in reducing mortality and morbidity associated with CVD(1). However, many patients revert to their original lifestyle once they are discharged from the clinic(2), highlighting the need to understand behavioural mechanisms and influences that can surround maintaining healthy behaviours. Ultimately this will enhance successful CR interventions. The aim of this study was to show how effective CR programmes were in improving and maintaining healthy lifestyle changes, comparing CR clinics in different environments; the UK and NZ. It assessed the experiences of former patients after their respective CR programme. Methods: Participants were previously discharged from CR by at least 6-12+ months; 16 males and 5 females from the Massey Cardiac Exercise Rehabilitation Clinic, NZ (phase III); 16 males and 6 females from the Wirral Heart Beat, UK (phase IV). These patients took part in focus groups consisting of 6-10 participants, which were recorded, transcribed and thematically analysed. In addition the CR programmes were observed over 2 months to enable 'reflection in practice'. Results: Both CR programmes were successful in supporting individuals to maintain healthy lifestyles. Similar positive CR experiences between groups and countries were noted; support, education, positive mental attitude, motivation facilitated maintaining healthy lifestyles. Diet and exercise were the main themes influenced, exercising in a friendly environment that provided support and companionship from other similar patients. Physical disabilities, time constraints, and weather conditions inhibited healthy behaviour maintenance. Those in NZ were more affected by other external factors; opportunity, access, and work commitments. Therefore, NZ participants had to be more active in seeking rehabilitative treatment, and be able to afford the service. Conclusion Continued support and a friendly structured exercising environment was the most prominent factor affecting behavioural change. The influence of external factors was more a reflection of the organisation of the respective health services and out of the individual's control, particularly in NZ. Overall, confidence appeared higher in the UK participants where they were more independent in monitoring their own symptoms. Future developments for NZ could include an improved referral process for CR intervention, along with less continual monitoring. For both countries, the introduction of education discussion groups could help tackle drop-out rates. 1. British Heart Foundation (BHF) (2007a). National Campaign for cardiac Rehabilitation. ### DIFFERENTIAL IMPROVEMENTS IN CARDIOMETABOLIC RISK AND FRAMINGHAM RECURRENT RISK SCORE IN PATIENTS WITH AND WITHOUT DIABETES MELLITUS UNDERGOING LONG-TERM CARDIAC REHABILITATION.

TSAKIRIDES, C., HOBKIRK, J., MOXON, J.W.P., DUDFIELD, M., INGLE, L., CARROLL, S.

LEEDS METROPOLITAN UNIVERSITY

Introduction: We evaluated whether cardiometabolic risk factors and recurrent coronary heart disease (CHD) risk could be modified in patients with and without diabetes mellitus, undergoing longer-term cardiac rehabilitation (CR). Methods: Patients attending a community-based CR, focusing on structured aerobic and resistance training, were retrospectively stratified into (i) patients with diagnosed CHD; (ii) patients with CHD and diabetes mellitus (CDM). Cardiometabolic risk factors and the 2-4 year Framingham recurrent CHD risk scores (FRS) were assessed at baseline and 15 months following CR. Results: One hundred and fifty four CHD patients (89% males; mean age  $59.6 \pm 8.5$  years; BMI  $27.0 \pm 3.5$  kg•m<sup>-2</sup>) and 20 patients with CHD and diabetes (CDM) (81% males; mean age  $63.0 \pm 8.7$  years; BMI  $28.7 \pm 3.3$  kg•m<sup>-2</sup>) completed 15 months of CR. At follow up, a significant main effect for time was evident for reduced body mass and waist circumference, and improved LDL-cholesterol concentration and sub-maximal cardiorespiratory fitness (all  $P < 0.05$ ), showing the benefits of CR

in both groups. However, a significant group by time interaction effect was evident for high density lipoprotein cholesterol (HDL-c), and total cholesterol/high density lipoprotein cholesterol ratio (TC/HDL-c ratio) (both  $P < 0.05$ ). CHD patients improved their TC/HDL-c ratio ( $5.0 \pm 1.5$  to  $4.4 \pm 1.3$ ), whereas this showed no improvement in CDM patients ( $4.8 \pm 1.6$  v  $4.9 \pm 1.6$ ). Conclusion: Anthropometric and sub-maximal fitness variables improved in all CHD patients following long-term CR. However, with the exception of a lowering of LDL-cholesterol, cardiometabolic risk profile improved only in the CHD group. Clinicians may consider more aggressive lipid-lowering and ACE inhibitor therapy in CHD patients especially amongst diabetics in order to improve cardiometabolic risk.

### THE EFFECT OF CONTINUOUS AEROBIC EXERCISE ON HOMOCYSTEINE OF CAD PATIENTS

SHEIKHSARAF, B.

IAU, NAJAFABAD BRANCH

F.Fathollahi Shoorabeh1, B.Sheikhsaraf2, H. Maleknia3, B. Tarverdzadeh4 1-BSc of physical Education, Shahrekord University 2-Faculty member of IA University, Najafabad Branch 3-Faculty member of IA University, Koozdasht Branch 4-Faculty member of IA University, Booshehr Branch Abstract Hyperhomocysteinemia is a risk factor for several disease especially coronary artery diseases (CAD). CAD patients have higher homocysteine (Hcy) levels. Little is known about the effect of exercise on Hcy. This study aimed to evaluate whether continuous exercise reduce Hcy levels for patients who had coronary artery bypass graft (CABG). For this purpose, 36 subjects who elapsed 3 months after their open heart surgery were selected. They didn't have exercise activity record and their BMI were under 30. They didn't have pulmonary disease like asthma, bronchitis and active chest pains or angina. Orthopedics and cerebra-neural which was an obstacle for exercise was not observed. They were randomly divided into groups: control (n=17) and experimental (n=17). Experimental group (continuous aerobic exercise) exercised for 8 weeks and each week for 3 sessions and each session for 41 minutes continuously with the intensity of 50-70% maximum heart rate (50-60% peak). 3-5 of first and last minutes were warm up and cool down. The ACSM formula was used for maximum rate of consumed oxygen. After 8 weeks the Homocysteine level was measured again. T-test was used for comparisons at significant level of 0.05 and SPSS version 16.0 for data analysis. Continuous aerobic exercise has significant effect on serum total homocysteine concentration of CABG patients ( $p=0.006$ ), while control group didn't have any significant change. The results of this study indicate that homocysteine can be kept at almost moderate, healthy levels if continuous aerobic exercise is used as a method of rehabilitation. Key word:

### MODIFICATIONS IN THE LIPID PROFILE AND CARDIOVASCULAR RISK FACTORS IN MARATHON RUNNERS.

BACHI, A.1, CAPEL, T.1, DIOGUARDI, G.2, GHORAYEB, N.2, MARANHÃO, R.3, VAISBERG, M.1

1 UNIVERSIDADE FEDERAL DE SÃO PAULO, 2 INSTITUTO DANTE PAZZANESE DE CARDIOLOGIA, 3 INSTITUTO DO CORAÇÃO DA UNIVERSIDADE DE SÃO PAULO

Introduction: Recently it has been shown that marathon runners present a coronary artery calcification (CAC) index similar to sedentary match controls. Oxidative stress caused by the marathon increases oxidation of LDL and can be involved with endothelial damage, which is implied with atherogenesis. The plasmatic percentage of cholesterol fractions is regulated by some mechanisms such as reverse transport promoted by HDL cholesterol that is regulated by donor and receptor lipoproteins. Methods: We evaluated the effect of marathon in lipoproteins, lipid profile and its effects on lipid transference, after the race. The study group was composed by 14 male runners with a range of age from 25 to 60 years (mean 41.4). The control group was composed by sedentary male, age matched to the study group. We evaluated the level of oxidative LDL (oxLDL, U/L), apolipoprotein A1 (ApoA1, g/L), apolipoprotein B (ApoB, g/L) and the transfer percent of free and esterified cholesterol (FC and EC), phospholipids (PL) and triglycerides (TG) in both groups at rest and in the marathoners immediately and 72 hours after race. Results: Our results showed that marathon runners had basal lipids transfer percent of FC [6.8(5.7-7.2)], PL [21.7(20.4-22.2)] and TG [3.7(3.1-4)] higher than control [5.2(4.5-6), 8.2(7.7-8.9) and 1.3(0.8-1.7),  $p=0.001$ ]. The transfer percent of EC [3.2(2.2-3.8)] and the serum levels of ApoA1 [161 (143-185)], ApoB [74 (64-85)] and oxLDL [85(76-96)] in marathoners at rest didn't show statistic differences comparing to controls [EC = 2.7(2.2-3), ApoA1 = 142(121-157), ApoB = 78(71-96), oxLDL = 86(55-118)]. However, immediately after the marathon we observed a significant decrease in percentual of all lipids transfer [FC = 5.8(4.9-6.6), PL = 19.1(18.6-19.3), EC = 2.3(2.2-2.9) and TG = 2.6(2.1-2.8),  $p < 0.05$ ] and increase in serum levels of ApoB [83 (61-101)] and oxLDL [110 (89-183),  $p < 0.05$ ] when compared with the results at rest. Only the ApoA1 levels [153(124-171)] didn't show statistical difference comparing to rest values. When we analyzed the lipids transfer percent and serum metabolites levels 72 hours after the marathon we observed that FC [6.4(5.8-6.9)], PL [20.9(19.8-22.1)], TG [3(2.6-3.5)] and ApoA1 [170(138-202)] were significantly increased ( $p < 0.05$ ) in relation to immediately after running percent, but other parameters didn't show statistical difference. Discussion: Although marathon runners at rest have more efficient mechanisms of lipid transport, immediately after the race they show a period of failure in lipid transference and an increase in oxidized LDL. Both alterations of lipid metabolism are associated to an increased risk of atherogenesis and could explain a CAC index in marathoners similar to controls.

### PHYSICAL ACTIVITY, PHYSICAL EXERCISE AND HIGH-DENSITY LIPOPROTEIN CHOLESTEROL

SABLONE, A., DI BLASIO, A., DI DONATO, F., IZZICUPO, P., D'ANGELO, E., RICCI, G., NAPOLITANO, G., RIPARI, P.

FACULTY OF SCIENCES OF MOTOR EDUCATION (CHIETI, ITALY)

Introduction Menopause is characterised by both hormonal and metabolic changes linked with an increased risk of cardiovascular disease. Low blood levels of HDL-cholesterol (HDL-c) are an independent risk factor for cardiovascular disease. Daily physical activity and aerobic exercise have been found linked with serum levels of HDL-c. Our study investigates the influencing variables of HDL-c, and the effect of 14 weeks of aerobic training. Methods Forty-nine post-menopausal women ( $56.25 \pm 4.74$  yrs) were enrolled in the study. Body composition was assessed by electrical bioimpedance technique, while SenseWear Pro3 Armband (Bodymedia) measured daily physical activity characteristics. The device gives information on total daily energy expenditure (DEE m/die), mean intensity of daily physical activities (METs m/die), and both time and energy spent (PAEE m/die) on physical activities with intensity  $> 3$  METs. By our software, we calculated the daily numbers of bouts of physical activities, with intensity  $> 3$  METs, lasting almost 5 (B5) and 10 (B10) consecutive minutes. Plasma lipoproteins were measured by ELISA kit. A dietician assessed dietary habits. Maximal stress test was performed to assess maximal aerobic capacity (Max METs). Women walked 4 days/wk, for 14 weeks, at moderate intensity. Results Pearson's correlation, performed on basal values, showed HDL-c negatively correlated with BMI ( $r = -0.304$ ,  $p = 0.034$ ), waist circumference ( $r = -0.353$ ,  $p = 0.013$ ), percentage fat mass ( $r = -0.303$ ,  $p = 0.034$ ), and positively correlated with METs m/die ( $r = 0.333$ ,  $p = 0.019$ ), B10 ( $r = 0.426$ ,  $p = 0.002$ ) and fiber intake ( $r = 0.287$ ,  $p = 0.045$ ). Linear regression indicated that basal values of B10 and fiber intake were the predictor variables of HDL-c

( $p < 0.001$ ). At the end of the study only daily steps ( $p = 0.010$ ) and METs m/die ( $p = 0.05$ ) were significantly improved. According to the variation of the HDL-c, participants were shared in GROUP+ ( $n = 28$ ), composed by women that increased it, and in GROUP- ( $n = 21$ ) composed by women that decreased it. Logistic regression was performed to investigate the influencing variables of HDL-c variation: basal value of HDL-c was the only significant ( $B = -0.079$ , Wald = 10.128,  $p = 0.001$ ). Discussion Together with fiber intake, qualitative-quantitative characteristic of spontaneous physical activity (i.e. B10) is important for plasma HDL-c of post-menopausal women. Several bouts of almost 10 consecutive minutes of physical activity at moderate intensity positively affect HDL-c profile. After the training, the variation of plasma HDL-c has been found linked with its basal value.

## EFFECTIVENESS OF POLAR ACTIVITY COMPUTER ON PHYSICAL ACTIVITY IN DAILY LIFE

RUCH, N., HÄNGGI, J., MÄDER, U.

FEDERAL INSTITUTE OF SPORT

**Introduction** Feedback and monitoring physical activity (PA) may have a role decreasing sedentary behavior. The aim of this study was to test the effectiveness of a Polar Activity Computer (FA20, Polar Electro Oy, Kempele, Finland) in increasing PA in daily life over 6 months. **Method** 50 volunteer healthy subjects were randomly assigned to an intervention (IG) (13 men, 13 women,  $48.9 \pm 2.3$  y,  $25.8 \pm 7.5$  kg/m<sup>2</sup>) and control group (CG) (14 men and 11 women,  $45.8 \pm 2.2$  y,  $24.9 \pm 7.6$  kg/m<sup>2</sup>) after baseline measurements. At baseline, all subjects wore an accelerometer (GT1M, Actigraph, Florida, USA) for 8 days and completed an online questionnaire on health and PA habits. After these measures the groups were randomised and the IG was given a general information on PA and provided with a Polar FA20. FA20 detects activity based on in-built accelerometer and gives the user feedback about active time spent in health and fitness related activity, accumulated steps and energy expenditure. The CG did receive only general information on PA. After one week and after two, four and six months, 8 days activity measures with the GT1M and the survey were repeated in both groups. The averaged GT1M data over the week (counts/min) was taken as mean PA per week. GT1M data was assigned to sedentary when activity was less than 100 counts. The remaining activity data was classified as light, moderate or vigorous according to Swartz et al (1). The data was analysed using Mixed Models to determine time and group effects on mean PA per week and time spent in moderate and vigorous activity (MVPA). **Results** The mean daily PA in the IG and CG was  $350 \pm 138$  and  $365 \pm 109$  counts/min at baseline, respectively. Time spent in MVPA was  $144 \pm 51$  and  $142 \pm 37$  min at baseline in the IG and CG, respectively. Mean daily PA and MVPA did not change over 6 months. There were no significant differences in PA between the groups at any measurement period. However, wearing the FA20 during the whole trial increased time spent in moderate activity ( $p = 0.007$ ) and nearly increased overall mean weekly PA ( $p = 0.059$ ). There was no effect of wearing the FA20 on light or vigorous activity. **Discussion** Mean daily PA at baseline was comparable to a population study (376 counts/min) (2) indicating that the participants of the present study are active at an average. Polar FA20 seems not to have a major effect on the general activity behaviour. However, wearing the FA20 regularly could increase moderate PA significantly over time in moderately active adults. **References** (1)Swartz, A. M., S. J. Strath, D. R. Bassett, JR., W. L. ### PP-PM25 Muscle Function

#### SHORT AND MID TERM EFFECT OF EMS STIMULATION ON CALORIC COST DURING DYNAMIC WHOLE BODY EXERCISE IN WOMEN

GERLINGS, I., HANAKAM, F., GUELLEND, L., FERRAUTI, A.

RUHR- UNIVERSITY BOCHUM/ FACULTY OF SPORT SCIENCE

**Introduction** Different studies have shown that Electromyostimulation (EMS) increases muscle activity during training (Colson et al., 2006). It could be hypothesized that during EMS training an additional energetic demand should be measured. Thus, the aim of the present study was to compare the caloric cost during dynamic whole body training with and without EMS. Furthermore it was examined if a repeated application attenuates the EMS effect after several training units of identical intensity. **Methods** Seven trained women ( $24.6 \pm 4.2$  yrs,  $172 \pm 6$  cm,  $63.6 \pm 7.0$  kg body mass,  $21.4 \pm 1.5$  BMI) participated in this study. All subjects completed an identical dynamic whole-body exercise protocol (8 exercises, each 2 min for a total duration of 20 min) on six experimental days. The subjects were trained with a pulse frequency of 85Hz, additionally to a pulse duration and interval of 4 seconds. During the first and second TU all subjects performed exercises with (TU1+) or without EMS (TU1-). The order of EMS applications was administered in a cross over design. For subsequent TU, similar EMS parameters were applied. The energetic cost during TU 1, 2 and 6 was calculated by means of spirometry and indirect calorimetry and the blood lactate concentration before and immediately after finishing the exercise was measured. **Results** No significant differences were found for energy consumption between TU1+ ( $4.37 \pm 0.80$  kcal·min<sup>-1</sup>), TU1- ( $4.09 \pm 0.93$  kcal·min<sup>-1</sup>) and TU6+ ( $4.46 \pm 0.68$  kcal·min<sup>-1</sup>,  $p > 0.05$ ). Likewise, blood lactate measurements did not show significant differences between TU1+ ( $5.20 \pm 2.45$  mmol·L<sup>-1</sup>), TU1- ( $5.20 \pm 1.09$  mmol·L<sup>-1</sup>) and TU6+ ( $5.37 \pm 2.45$  mmol·L<sup>-1</sup>,  $p > 0.05$ ). **Discussion** The present study demonstrates that caloric consumption remains unchanged during dynamic whole-body exercise despite EMS application. Obviously, the potential effects of EMS-workout on muscle fiber recruitment and on overall muscle work seem to be lower than expected under the conditions of our study. Only a slight trend towards a higher caloric cost with EMS application was identified, which was stable until TU6+. Further studies with different EMS parameters and exercises have to be performed. Nevertheless, the overall effect seems to be lower than promoted. **References** Kemmler, W.; Schliffka, R., Mayhew, J. & von Stengel, S. (2010). *J. Strength Cond. Res.*, 24 (7), 1880-1887. #### FATIGUE-INDUCED CHANGES IN LONGITUDINAL RELAXATION TIME OBTAINED BY MAGNETIC RESONANCE IMAGING

TAKAHASHI, K.1, TOHDOH, Y.2, MATSUBAYASHI, T.1, OHTA, Y.1

JAPAN INSTITUTE OF SPORTS SCIENCES

**Background** Several studies have reported that the transverse relaxation time (T2) obtained by magnetic resonance imaging (MRI) is well related to muscle fatigue. However, the relation between longitudinal relaxation time (T1) and fatigue has not been well investigated.

**Objective** The purpose of this study was to clarify the relation between T1 and muscle fatigue. **Methods** In experiment 1 (Exp. 1), 11 subjects performed a fatiguing exercise involving 3 bouts (i.e., E1, E2, and E3) of 120-sec repeated right-ankle dorsiflexion at 1 Hz frequency with 5-min between-bout rest. Thirty percent of maximum voluntary dorsiflexion torque (MVC) measured at an ankle angle of 90° was used as resistance in the exercise. T1 values were obtained for lower thigh muscles (tibialis anterior [TA], extensor digitorum longus [EDL], and soleus [Sol]) using a 3.0-tesla MRI scanner (Verio; Siemens, Erlangen, Germany) before the first bout, immediately after each bout, and 15 and 30 min after the last bout. In experiment 2 (Exp. 2), another 8 subjects performed the same exercise described above and the MVCs were measured at the same time points as T1 measurement in Exp. 1. In addition, an electromyography (EMG) was obtained from the TA muscle during the exercise and the MVC measurement. **Results** In Exp. 1, the T1 values for the TA and EDL muscles increased gradually along with the progression of the test periods E1, E2, and E3. Thereafter, the values decreased in the recovery period, though they remained higher than the pre-exercise value. The T1 value for the Sol muscle was unchanged throughout the experiment. In Exp. 2, the MVC after each bout decreased gradually. On the other hand, during each bout, the root mean square (RMS) of EMG of the TA muscle gradually increased during the exercise. **Conclusions** The T1 values of the TA and EDL muscles increased gradually along with the development of muscle fatigue (increase in the RMS of EMG and decline in the MVC of the exercised muscle). The present results suggest that T1 is also well related with muscle fatigue, similar to T2.

## HUMAN MUSCLE FORCE RECOVERY IN RELATION TO MUSCLE OXYGENATION LEVEL

UFLAND, P., LAPOLE, T., AHMAIDI, S., BUCHHEIT, M.

UNIVERSITY OF PICARDIE

**Human muscle force recovery in relation to muscle oxygenation level** Ufland, P.1, Lapole, T.1, Ahmaidi, S.1, Buchheit, M.1.2 1: EA-3300, UPJV (Amiens, France), 2: ASPIRE (Doha, Qatar) **Introduction** In many sports, such as rugby or judo, the ability to repeat maximal force application separated by short recovery periods is one of the principal determinants of physical performance. The aim of this study was therefore to investigate the relative contribution of human muscle reoxygenation on force recovery following a maximal voluntary contraction (MVC). **Methods** Ten athletes ( $22.9 \pm 4.0$  yr,  $181.9 \pm 6.3$  cm,  $78.6 \pm 5.8$  kg) were asked to execute a plantar-flexion sequence including repeated MVCs (a 30-s MVC (MVC30) followed by a 10-s MVC (MVC10) separated by either 10, 30, 60, 120 or 300 s of passive recovery. A 10-min passive recovery period was allowed between each MVC sequence. This procedure was randomly repeated with two different recovery conditions: without (CON) or with (OCC) arterial occlusion of the medial gastrocnemius. During OCC, the occlusion was maintained from the end of MVC30 to the end of MVC10. Muscle oxygenation (Near infrared spectroscopy, NIRS, [HbDiff]) was continuously measured during the all MVC sequences and expressed as a percentage of the maximal changes in optical density (diffOD) observed during MVC30. Maximal torque was analyzed at the beginning of each contraction (within the first 5 s, when the force production was stable). Torque values during MVC10 were expressed as a percentage of the maximal torque observed during each MVC30. **Results** While torque recovery was complete within 3 min after MVC30 during CON (MVC10 =  $101.8 \pm 5.0\%$ ), only  $88.6 \pm 8.9\%$  of the torque was recovered during OCC ( $P = 0.005$ ). There was also a moderate correlation between absolute level of muscle oxygenation and torque ( $r = 0.32$ ,  $P = 0.02$ ). **Discussion** While the possible detrimental effects of the occlusion on metabolite clearance cannot be determined, present findings confirm the role of human muscle oxygenation in muscular force recovery during repeated maximal efforts. However, the correlation between absolute muscle oxygenation level and force recovery is only moderate, suggesting that other mechanisms not evaluated here are involved in the force recovery process (e.g., phosphocreatine resynthesis, peripheral neuromuscular adjustments).

## DIFFERENCES IN CO-ACTIVATION AROUND THE HIP AND KNEE JOINT DURING THE ROUNDHOUSE KICK: ELITE VS. AMATEUR KARATEKA

QUINZI, F., SBRICCOLI, P., CAMOMILLA, V.

UNIVERSITY OF ROME

**DIFFERENCES IN CO-ACTIVATION AROUND THE HIP AND KNEE JOINT DURING THE ROUNDHOUSE KICK: ELITE VS. AMATEUR KARATEKA** Quinzi, F.1, Sbriccoli P.1, Camomilla V.1 1: Department of Human Movement and Sport Sciences, Università degli Studi di Roma "Foro Italico" **Introduction** The issue of agonist and antagonist co-activation during the execution of a movement is of interest especially considering sport activities like karate where a fine control of movement has to be associated to a great ability to perform the main technical actions as fast as possible (Sørensen et al., 1996). Sbriccoli et al., (2010) reported in elite Karateka (vs. Amateurs) a reduced co-activation of knee flexor and extensor muscles during an isokinetic task that was paralleled by a higher antagonist activation during the extension phase of a front kick. Because of its high speed and excellent accuracy, the roundhouse kick (RK) seems to be a better model to quantify the ability of a karateka to perform complex actions. This work was then designed to study the co-activation pattern adopted during the RK performed by elite Karateka and Amateurs, with two different techniques: Low Roundhouse Kick (LRK) and High Roundhouse Kick (HRK). **Methods** Six elite Karateka ( $24.8 \pm 1.0$  yrs,  $1.78 \pm 0.03$  m,  $73.8 \pm 4.0$  kg) and six Amateurs ( $27.8 \pm 1.0$  yrs,  $1.80 \pm 0.03$  m,  $77.0 \pm 3.6$  kg) performed 3 LRK and 3 HRK. The surface Electromyographic (sEMG) signal was recorded from the Vastus Lateralis (VL); Biceps Femoris (BF), Rectus Femoris (RF), Gluteus Maximus (GM), and Gastrocnemius Lateralis (GAL) muscles of the kicking leg using a wi-fi EMG amplifier (BTS PocketEMG) during LRK and HRK. Co-activation ratios of antagonist vs. overall activity were computed for knee and hip flexion and extension. Considering the bi-articular role of RF, for the knee joint three co-activation indexes were computed: extension with mono and bi-articular muscles (KClextM and KClextB, respectively), and flexion (KCiflex). For the hip joint, the Hip flexion (HCiflex) and Hip extension (HCext) co-activation indexes were calculated. The effect of Group (Karateka and Amateurs) and Kick (LRK and HRK) on all co-activation indexes was tested through a two-way ANOVA ( $p < 0.05$ ). **Results** The ANOVA demonstrated an effect of Group on all co-activation indexes computed ( $p < 0.001$ ). Namely, Elite Karateka showed lower HCiflex, KClextM and KClextB and higher KCiflex and HCext. **Discussion** Elite Karateka exhibited in general a neuromuscular strategy towards antagonistic activity reduction. Increases in such activity could be attributable to the RF muscle agonist activities (hip extensor during knee flexion and hip abductor during hip extension). Surprisingly, this inhibitory or facilitating response does not seem to be Kick-related. This may be attributed to slight differences in the execution technique between the subjects. **References** Sørensen, H. et al (1996). J Sports Sci, 14, 483-495. Sbriccoli, P. et al (2010). ### TRAINING AT AN ELONGATED MUSCLE LENGTH MAXIMISES MUSCLE SIZE AND STRENGTH

MCMAHON, G., MORSE, C.I., BURDEN, A.M., WINWOOD, K., ONAMBÉLÉ, G.L.

MANCHESTER METROPOLITAN UNIVERSITY

**Introduction** Muscle strength adaptations to resistance training (RT) are joint-angle specific (Thepaut-Matieu, Van Hoecke & Maton, 1988). However the effects of RT at different muscle lengths on concomitant changes to muscle size, architecture and strength remain largely unreported. Therefore the aim of this study was to identify differences to training at a longer (LL) compared with a shorter (SL) muscle length, as well as the time-course of any changes during detraining. **Methods** LL (aged  $19 \pm 2.6$  years;  $n=8$ ) and SL (aged  $19 \pm 3.4$  years;  $n=8$ ) groups undertook 8 weeks of dynamic RT and 4 weeks detraining. Muscle volume, architecture and strength were measured at weeks 0, 8, 10 and 12. A control group (aged  $23 \pm 2.4$  years;  $n=10$ ) was also monitored during this period. **Results** There was a significant effect of training group ( $P<0.05$ ) on strength ( $13 \pm 2\%$  vs.  $6 \pm 2\%$ ) and fascicle length ( $22 \pm 4\%$  vs  $13 \pm 2\%$ ), with LL exhibiting greater adaptations than SL. Muscle volume increased significantly ( $P<0.05$ ) as a result of the training protocol and compared to controls ( $P<0.05$ ) in both training groups ( $69 \pm 21\%$  LL vs  $39 \pm 12\%$  SL) with no difference between groups. Detraining resulted in significant ( $P<0.05$ ) deteriorations in all muscle parameters measured in both groups, with SL group experiencing a more rapid relative loss of post-exercise increases in strength than LL ( $P<0.05$ ). **Discussion** Training at a longer muscle length increases muscle stretch (Tabary et al., 1972) and mechanical stress via alterations to the tendon moment arm (Kubo et al., 2006), compared to a shorter muscle length, with each factor being a potent stimulus for protein synthesis (Goldspink, 1999). Increased serial sarcomeregenesis in fascicle length, translated externally as a greater increase in muscle volume, produced greater adaptation and retention of functional capabilities. Therefore a protocol which maximises training gains in a limited amount of time would be key to helping with compliance to exercise training and/or reversing the deleterious effects of prolonged bed rest/ immobilisation (e.g. caused by illness or injury). In addition, whilst the paradigm of 'use it or lose it' is still true, longer muscle length training provides a much better prognosis for long-lasting maintenance of the benefits of exercise, even after cessation of the training regime. **References** Goldspink, G (1999). *J Anat*, 194, 323-334. ### DISTINCT SPATIAL DISTRIBUTION ACTIVATION PATTERN IN THE HUMAN RECTUS FEMORIS MUSCLE DURING KNEE EXTENSION AND HIP FLEXION

WATANABE, K., KOUZAKI, M., MORITANI, T.

KYOTO UNIVERSITY

**Introduction** Strain injury of the rectus femoris (RF) muscle is a frequent problem in many athletic activities (Hasselman et al., 1995). On the other hand, functional role or activation properties of this muscle had not been fully understood. RF muscle had reported to be innervated by two nerve branches attached at proximal and distal regions of the muscle in humans (Sung et al., 2003). In animal studies (e.g., Pratt et al., 1991), distinct functional roles among the regions innervated by different nerve branches were demonstrated within a muscle. However, functional role of the human RF muscle related with specific innervation pattern has not been investigated in detail. The purpose of the present study is to clarify the possible region-specific functional role in the human RF muscle. **Methods** Eleven healthy men performed isometric knee extension and hip flexion at 20, 40, 60, and 80% of maximal voluntary contraction. During these tasks, multi-channel surface electromyography (SEMG) was recorded from the RF muscle by using 128 electrodes (26 rows and 5 columns with 2 missing electrodes). The rows of electrodes were placed along the longitudinal axis of RF muscle. Superficial region of the RF muscle was defined by ultrasonography and the most part of that was covered with electrodes. Root mean square (RMS) was calculated for all electrode pairs along the rows. **Results** Central locus activation during hip flexion was at more proximal region compared with that during knee extension ( $p < 0.05$ ). While similar RMS values were obtained among different regions during knee extension, significantly higher RMS values were observed at the proximal regions when compared with those at middle and distal regions during hip flexion ( $p < 0.05$ ). **Discussion** The results of the present study suggest that in human RF muscle most part of the muscle play as knee extensor and the proximal regions mainly plays as hip flexor. Moreover, these region-specific EMG patterns for different tasks could be explained by the specific innervation pattern i.e., the proximal and distal regions of the RF muscle are innervated by different nerve branches (Sung et al., 2003). The present study shed some light into the understanding of functional roles or mechanisms of sports injuries such as strain injury in the RF muscles and other bi-articular muscles during athletic activities. **References** Hasselman C T, Best T M, Hughes C, Martinez S and Garrett W E Jr. (1995) *Am J Sports Med*, 23 (4):493-9 Pratt C A, Chanaud C M and Loeb G E. ### LOW-LOAD FATIGUING RESISTANCE TRAINING WITH HIGH REPETITION PRODUCES MUSCLE HYPERTROPHY, BUT NO STRENGTH GAINS, COMPARABLE TO THAT ELICITED BY TRADITIONAL HIGH-LOAD RESISTANCE TRAINING

OGASAWARA, R., ABE, T.

UNIVERSITY OF TOKYO

**Introduction** It is generally accepted that Low-load (<50% of 1-repetition maximum [1-RM]) resistance training is not of optimal intensity to elicit muscle hypertrophy, while muscle fatigue (until failure) is considered an important factor to optimize the effect of resistance training. A recent study reported that low-load (30% of 1-RM) resistance exercise with repetition to failure increases post-exercise myofibrillar protein synthesis to a similar extent as high-load resistance exercise (Burd et al. *PLoS One* 5: e12033, 2010). We hypothesized that low-load fatiguing resistance training (LL-RT) would produce muscle hypertrophy. Thus, the purpose of the current study was to examine the effect of LL-RT on muscle size and strength and compare it with the effect of traditional high-intensity resistance training (HI-RT) on the same subjects. **Methods** Nine young men who had previously participated in 6 weeks of HI-RT (3 d/wk, 75% 1-RM  $\times$  10 repetitions  $\times$  3 sets) performed LL-RT for 6 weeks (3 d/wk, 30% 1-RM until failure  $\times$  4 sets). At least 7 months prior to LL-RT, none of the subjects had regularly participated in a resistance training program. The cross-sectional area (CSA) of the triceps brachii (TB) and pectoralis major (PM) muscles was measured using magnetic resonance imaging before and 3 days after the final training session. Maximal dynamic bench press (1-RM) strength and isometric elbow extension (MVC) strength were measured three times (before, after week 3, and after week 6). Electromyographic (EMG) activity of TB and biceps brachii (BB) muscles during MVC was recorded. **Results** At baseline, there were no significant differences in TB and PM muscle CSA between the two groups. After 6 weeks of training, The TB and PM muscle CSA increased 11.9% and 17.6% (both  $P<.001$ ), respectively, in the HI-RT group, and 9.8% and 21.1% (both  $P<.001$ ), respectively, in the LL-RT group. The percent increases in TB and PM muscle CSA were not significantly different ( $P>.05$ ) between the two groups. On the other hand, pretrain-

ing 1-RM strength ( $P<.001$ ) and MVC strength ( $P<.05$ ) were significantly higher in the LL-RT group (1-RM, 61.1 kg; MVC, 34.5 Nm) than in the HI-RT group (1-RM, 51.1 kg; MVC, 31.9 Nm). Percent increases in 1-RM and MVC strength in the HI-RT group (1-RM, 21.0%,  $P<.001$ ; MVC, 13.9%,  $P<.05$ ) were greater than in the LL-RT group (1-RM, 8.6%; MVC, 6.5%). Integrated EMG (iEMG) tended ( $P=.08$ ) to increase in the HI-RT group (32.7%), but not in the LL-RT group (-5.9%,  $P=.79$ ). Conclusion Our results suggest that low-load, 30% 1-RM intensity resistance training can elicit muscle hypertrophy that is comparable to that elicited by HI-RT. However, increases in dynamic and isometric strength were greater in the HI-RT group than in the LL-RT group, which may be due to retraining-induced neuromuscular adaptation.

### IS AGE-RELATED THIGH MUSCLE MASS LOSS MUSCLE SPECIFIC?

OGAWA, M., YASUDA, T., ABE, T.

THE UNIVERSITY OF TOKYO

Introduction Skeletal muscle mass loss with increased age is greater in the lower limbs than in the upper extremities (Janssen et al., J Appl Physiol 89:81-88, 2000). However, it is not fully understood whether age-related changes in muscle mass differ between muscle groups in the lower limbs. The purpose of this study was to compare the muscle mass of the thigh muscle groups in young and old Japanese men. Methods Fifteen young ( $24.3 \pm 1.6$  yrs) and 13 old ( $68.6 \pm 7.8$  yrs) men were recruited for this cross-sectional study. The subjects in both groups were physically active, but none of the subjects had regularly participated in strength/resistance training (less than once a week) for a minimum of 3 years prior to the study. Contiguous transverse MRI (1.5-T scanner) images with 1.0-cm slice thickness were obtained from the thigh, and the total thigh and individual (quadriceps, hamstrings, and adductor) muscle tissue volumes were calculated by multiplying the muscle cross-sectional area (CSA) by slice thickness and the total number of slices. Muscle length (number of slices) and average muscle CSA (muscle volume divided by muscle length) were determined for each muscle. Isometric knee extension and flexion torques were measured using a Biodex System-3 dynamometer. Results The young men were taller than the old men ( $1.71 \pm 0.04$  m and  $1.62 \pm 0.03$  m, respectively), while body weight was similar in both groups ( $65.4 \pm 6.3$  kg and  $63.8 \pm 6.4$  kg, respectively). Total thigh muscle volume was 13.4% lower ( $P<.05$ ) in the old men ( $2890 \pm 421$  cm<sup>3</sup>) than in the young men ( $3338 \pm 372$  cm<sup>3</sup>). Quadriceps muscle volume was also 20.3% lower in the old men than in the young men ( $1716 \pm 204$  cm<sup>3</sup> and  $1368 \pm 237$  cm<sup>3</sup>, respectively), while hamstrings ( $704 \pm 120$  cm<sup>3</sup> and  $641 \pm 79$  cm<sup>3</sup>, respectively) and adductor ( $918 \pm 124$  cm<sup>3</sup> and  $882 \pm 149$  cm<sup>3</sup>, respectively) muscle volumes were similar in both groups. There was a significant correlation between quadriceps and adductor muscle volume in both the young ( $r=0.59$ ,  $P<.05$ ) and old ( $r=0.60$ ,  $P<.05$ ) men, but quadriceps muscle volume did not correlate with hamstrings muscle volume in both groups ( $r=0.38$  and  $r=0.50$ , respectively). Isometric knee extension and flexion torques were lower in the old men ( $167 \pm 21$  Nm and  $73 \pm 15$  Nm, respectively) than in the young men ( $246 \pm 55$  Nm and  $90 \pm 21$  Nm, respectively). However, relative strength (torque divided by average muscle CSA) was similar in both the young and old groups. Conclusion Our results indicate that age-related thigh muscle mass loss is muscle specific, in that greater quadriceps muscle loss was found in the old group. A main contributor to decreased muscle strength with aging is the loss of muscle mass, which surpasses the neural factor in importance.

### RELIABILITY OF SOME PARAMETERS FREQUENTLY USED FOR THE EVALUATION OF EXPLOSIVE FORCE PRODUCTION

TROST BOBIC, T.1, MARKOVIC, G.1, SARABON, N.2

1:SCHOOL OF KINESIOLOGY UNIVERSITY OF ZAGREB, CROATIA, 2: SCIENCE AND RESEARCH CENTRE, UNIVERSITY OF PRIMORSKA, KOPER, SLOVENIA

RELIABILITY OF SOME PARAMETERS FREQUENTLY USED FOR THE EVALUATION OF EXPLOSIVE FORCE PRODUCTION Trošt Bobić, T.1, Marković, G.1, Šarabon, N.2 1: School of Kinesiology, University of Zagreb, Croatia, 2: Science and Research Centre, University of Primorska, Koper, Slovenia Introduction The aim of this study was to evaluate the intra- and inter-session reliability of numerous dynamometric (DY) and electromyographic (EMG) parameters which are frequently used for the evaluation of explosive force production (EFP). Methods Thirty-seven physical education students ( $22.5 \pm 1.3$  years) were included in the intra-session, while ten ( $22.7 \pm 0.9$  years) were included in the inter-session reliability study. Sitting on a custom made dynamometer, participants were asked to perform three unilateral maximal voluntary isometric plantar flexions of the right foot stressing EFP. EMG signals of m. soleus were recorded by means of surface bipolar electrodes. Altogether sixteen DY and EMG parameters, which are frequently used to evaluate EFP, were computed from the recorded and preprocessed force and EMG signals. Three components of reliability were calculated: systematic bias, within-individual variation, and retest correlation (Hopkins, 2000). Results Intra-session reliability - Within individual variation (CV) varied 13.8-18% for almost all the DY parameters (i.e. k slope, max. average force, RFD) established in the time intervals of 30 and 50 ms. When the same parameters were extracted for 100 and 200ms CV remained in the range of 7.3-12.9%. The majority of DY parameters had a high intra-session ICCs (ICC=0.84-0.94), while the EMG ICCs (for variables like root mean square and rate of EMG rise) were quite low (almost all ICC values under 0.45). Inter-session reliability - CV ranged 5.8-17.5% for the DY and 17.9-109.7% for the EMG parameters. High inter-session reliability was obtained only for almost all DY parameters (ICC=0.81-0.9 compared with the ICC for the EMG parameters being mostly under 0.5). Setting the beginning of the action at 3% MVC level showed slightly better reliability results than the other criteria used. Discussion The results showed a better inter- and intra-session reliability of the DY parameters compared with the EMG parameters. This is in line with the so far knowledge (Claiborne et al., 2009). The main finding of this investigation is that the DY parameters have better inter- and intra-session reliability when calculated for the time interval of 100 and 200ms MVC, rather than for 30 and 50ms respectively. Such data suggests that the indicators of EFP should be calculated in the time range of 100 to 200ms MVC. It also seems that setting the starting point on 3% MVC could be an appropriate choice for the calculation of EMG parameters. References Hopkins WG (2000). Sports Med, 30(1):1-15. ### EFFECTS OF CONDITIONING AND PLYOMETRIC JUMPS TRAINING ON THE BODY COMPOSITION OF YOUTHS WITH DOWN SYNDROME

GONZÁLEZ-AGÜERO, A., VICENTE-RODRÍGUEZ, G., OLMEDILLAS, H., GÓMEZ-CABELLO, A., ARA, I., MORENO, L.A., CASAJÚS, J.A.

GENUD (GROWTH, EXERCISE, NUTRITION AND DEVELOPMENT) RESEARCH GROUP, UNIVERSITY OF ZARAGOZA, ZARAGOZA, SPAIN.

Introduction: Children and adolescents with Down syndrome (DS) tend to have unhealthier body composition compared with their peers without DS in regard to fat, lean and bone masses.(1) Material and methods: 28 participants with DS (15 males) aged from 10 to 18 years and 30 sex- and age-matched healthy controls without disabilities joined the study. Participants with DS were divided into two groups:

DS-exercise and DS-control. The DS-exercise group conducted a 21-week conditioning consisted of 2 sessions per week of circuits including different kind of jumps, press-ups, exercises with elastic fitness bands and adapted medicine balls, for approximately 15 to 25 minutes/day. The DS-control group and the non-DS controls continued with their typical weekly activities. Percentage of body fat (%BF), total lean mass, bone mineral content (BMC) and density (BMD) were measured by dual energy X-ray absorptiometry (DXA) at baseline and after the training program. Percentages of change of total lean mass, BMC and BMD were calculated for each variable, and Mann-Whitney U tests were used to evaluate differences between groups. Results: Overall, the DS-exercise group increased significantly more the lean mass, BMC and BMD than the DS-control group (3.1, 3.8 and 1.8 % respectively; all  $p < 0.05$ ); however, these increments did not differ from the non-DS control group. No differences were found in %BF between groups neither pre nor post-training. Conclusion: The conditioning and plyometric jumps training may be useful to get higher increments in BMC, BMD and lean mass in a population of youths with DS, despite we did not find a reduction on the %BF. Further research in this area could help to clarify whether these changes occur in the same mode in non-disabled populations. ### PP-PM26 Fatigue and Exercise Testing

#### MAXIMAL EXERCISE PERFORMANCE IN RELATION TO FATIGUE AND SELF-EFFICACY IN PATIENTS WITH POSTCANCER FATIGUE

PRINSEN, H.1, HOPMAN, M.T.E.2, ZWARTS, M.J.3, HEERSCHAP, A.4, BLEUENBERG, G.5, VAN LAARHOVEN, H.W.M.1  
*RADBOUD UNIVERSITY NIJMEGEN MEDICAL CENTRE*

Background Fatigue after curative cancer treatment is a frequently occurring problem, impairing quality of life. Little is known about physiological factors determining postcancer fatigue. Purpose To examine maximal exercise performance in relation to fatigue and self-efficacy in patients with postcancer fatigue. Methods Severely fatigued ( $n=20$ ) and matched non-fatigued ( $n=18$ ) disease-free cancer survivors, who completed treatment for a malignant tumor at least one year earlier, participated in this case-control study. Fatigue severity was measured by the fatigue severity subscale of the Checklist Individual Strength (CIS-fatigue). Self-efficacy was measured using a task-specific self-efficacy questionnaire. Maximal oxygen consumption was measured during an incremental cycling exercise test using an automated gas analyzer. Results CIS-fatigue scores were significantly higher and self-efficacy scores were significantly lower in fatigued (men 48.3(5.7) and 26.8(2.6), women 49.1(4.3) and 25.6(1.6), respectively) compared to non-fatigued participants (men 13.2(4.4) and 32.1(3.0), women 13.8(6.2) and 30.5(3.4), respectively). Maximal oxygen consumption was significantly lower in fatigued (men 26.8(5.2), women 25.2(6.8) ml/min/kg) compared to non-fatigued postcancer patients (men 38.2(9.7), women 30.4(3.8) ml/min/kg). CIS-fatigue and self-efficacy scores significantly correlated with maximal oxygen consumption (-0.577 and 0.475, respectively). Discussion and conclusion Maximal exercise performance and related maximal oxygen consumption were reduced in fatigued compared to non-fatigued cancer survivors and correlated with higher CIS-fatigue scores and lower self-efficacy scores. The lower maximal exercise performance may be explained either by differences in pre-cancer fitness or by differences in self-efficacy in daily life between severely fatigued and non-fatigued cancer survivors, leading to an inactive lifestyle in the group suffering from postcancer fatigue.

#### FATIGUE AFTER RUNNING MODULATED SPECIFIC REFLEX COMPONENTS OF THE THIGH MUSCLES BUT DID NOT AFFECT POSTERIOR-ANTERIOR TIBIAL TRANSLATION

BEHRENS, M., MAU-MÖLLER, A., WERNER, D., BRUHN, S.  
*UNIVERSITY OF ROSTOCK*

Introduction Epidemiological data indicate that injury rates tend to be higher at the end of matches (Price et al., 2004), suggesting fatigue could be related to injury. Rupture of the anterior cruciate ligament (ACL) rank among the most common injuries in sports (Hootman et al., 2007). Therefore, the purpose of the present study was to investigate how posterior-anterior tibial translation and the activity of the hamstring and quadriceps muscles are influenced by fatigue. Methods In 19 healthy subjects, posterior-anterior tibial translation, onset latencies of reflex responses and muscle activity of hamstring and quadriceps muscles were assessed. Data were obtained before, immediately after (post), 30min after (post-30min) and 60min after (post-60min) fatigue which was induced by incremental treadmill running. Reflex responses were evoked by a mechanically induced posterior-anterior tibial translation in the sagittal plane during standing. The distance of posterior-anterior tibial translation was assessed using a knee arthrometer. For statistical analyses, One Way Repeated Measures ANOVA and Friedman Repeated Measures ANOVA on Ranks were used ( $p = 0.05$ ). Results Posterior-anterior tibial translation did not change after the fatigue protocol. The EMG onset latencies of the hamstrings were increased at post, post-30min and post-60min. At post and post-30min, background activity of the hamstrings was enhanced. The reflex responses of the hamstrings were decreased whereas quadriceps activity was increased at the same time. At post-60min, background activity of the hamstrings was highest and the reflex responses were partially recovered. Discussion Fatigue after running did not affect posterior-anterior tibial translation. At post and post-30min, the increased background activity of the hamstrings as well as the enhanced quadriceps activity probably compensated for the exercise-induced decline in hamstring reflex activity and therefore likely contributed to functional knee stability. The decreased reflex activity could originate from (I) fatigue-induced change of intrafusal properties (Zhang et al., 2001), (II) presynaptic inhibition of Ia afferents mediated by group III and IV afferents and (III) changes in intrinsic properties of motoneurons (Racinais et al., 2007). At post-60min measurement, the peaked background activity of the hamstrings and the partially recovered hamstring reflexes probably preserved functional knee stability. ## RELATIONSHIP BETWEEN RFD AND SPRINT PERFORMANCE IN RESISTED SPRINTING TOWING A RANGE OF RELATIVE LOADS

MARTINEZ-VALENCIA, M.1, ROMERO-ARENAS, S.2, ELVIRA, J.L.L.3, ALCARAZ, P.E.2

1 UCLM (TOLEDO, SPAIN), 2 UCAM (MURCIA, SPAIN), 3 UHM (ELCHE, SPAIN)

**Introduction:** Resisted sprint running (RST) has become a specific strength training method for sprinters (Alcaraz et al., 2008). Cronin and Sleivert (2005) suggested the improvements in athletics tasks that involve significant power output would be gained by training at the load that maximised and individual's power output using an exercise similar to their athletic activity. These authors set strength qualities such as rate of force development (RFD) may better predict athletic performance. However, no studies have showed the relationship between RST and any strength qualities. The main purpose of this research was to determine the relationship between force values and sprint performance in RST, in order to determine the optimal load for RST in the acceleration phase of sprinting. **Methods:** Seventeen men were recruited for the study ( $17.9 \pm 3.3$  years,  $1.79 \pm 0.06$  m and  $69.4 \pm 6.1$  kg). The participants were active competitive athletes who specialized in sprinting. Subjects had previously sled-towing training experience. The athletes performed four 30-m sprints (unloaded sprints and sprints pulling resistances of 10, 15 and 20% of Bm) from a crouched start. The participants were placed 1-m behind the starting line, avoiding the influence of reaction time. The trials' order was randomized for each participant, and an unlimited rest period was given between trials to minimize the effects of fatigue on sprint performance. The sprint trials were performed using a weighed sled (4.7 kg) attached to each athlete by a 3.6-m cord and waist harness. The sprint times were recorded by a photocells system placed at 0, 20 and 30-m. A load cell was attached between waist harness and cord to assess changes in force production over 60-m sprint. RFD was recorded for each trial in the first step. RFD was calculated using the following equation in a 0.02-s period:  $RFD = \Delta F / \Delta t$ . The maximal velocity was measured through the use of a radar gun. **Results:** A Pearson's Product moment correlation coefficient showed that there was no significant association between RFD in resisted sprint and sprint performance in acceleration phase (20 and 30 m without load). No significant correlations were found between RFD and maximal velocity recorded in 30m-sprint unloaded and loaded. **Discussion:** The lack of correlation between sprint performance and RFD in resisted sprint suggested that the strength's behavior in resisted sprint is not representative of changes in sprint performance. In order to determine the optimal load for resisted sprint training new research should be developed in relation to strength qualities. **References:** 1. ## ACUTE EFFECTS WITHIN 5 DAYS OF DAILY WHOLE-BODY VIBRATION TRAINING ON LEG MUSCLE ACTIVITY, HEART RATE, BLOOD PRESSURE, LACTATE AND IGF-1

ROSENBERGER, A., BARGMANN, A., MÜLLER, K., BECK, L., LIPHARDT, A.M., MESTER, J., ZANGE, J.

GERMAN AEROSPACE CENTER

**Acute effects within 5 days of daily whole-body vibration training on leg muscle activity, heart rate, blood pressure, lactate and IGF-1** Rosenberger, A.(1,2), Bargmann, A.(1,3), Müller, K.(1), Beck, L.(1), Liphardt, A-M.(1,2), Mester, J.(2), Zange, J.(1,3) 1: German Aerospace Center (Cologne, Germany), 2: German Sport University Cologne (Cologne, Germany), 3: University of Cologne (Cologne, Germany) **Introduction** Whole-body vibration training (WBVT) has become a popular method in recreational and athletic training and rehabilitation medicine. Acute effects of WBVT as well as long term effects of WBVT have intensively been studied in recent years (for review see Rittweger, 2010). However, little is known about the changes in the acute effects of WBVT on muscle activity and autonomic functions during the initial days of a daily training. We tested the hypothesis that WBVT during slow squats in comparison to mere squats (conventional resistive training, CRT) causes excess muscular activity and cardiovascular reactions over 5 days of daily training. **Methods** Electromyography (EMG) was recorded on the m. rectus femoris and the m. gastrocnemius lateralis. Electrocardiogram (ECG) and continuous finger blood pressure was recorded using a separate data acquisition system (BIOPAC-Systems, Goleta, CA, USA). **Results** On day 1, EMG amplitudes in m. rectus femoris were higher by 36% during WBVT than during CRT. This difference was reduced to insignificantly different levels on day 5. During WBVT, the increase in heart rate (HR) was 15 beats per minute higher than during CRT on day 1. This difference declined and was not significant anymore on days 4 and 5. Net lactate formation was the highest on day 1 ( $3.8 \pm 2.6$  mmol/l in WBVT vs.  $1.2 \pm 1.9$  mmol/l in CRT). On the following days, these differences declined, but still reached statistical significance. Morning and post training levels of IGF-1 were not altered by WBVT and CRT. **Discussion** In most variables, excess effects of WBVT over CRT were largest on the initial day of training and declined to insignificant levels within following days. The higher initial values of the EMG, HR and lactate were expected because vibration training is an additional stress for the human body (Rittweger et al., 2003; Torvinen et al., 2002). Furthermore, WBVT was a new experience for all subjects and needed a more conscious execution of the squats which may have led to worse coordinated and less efficient squats at the beginning of the vibration training. However, the decreasing EMG amplitudes showed a rapid adaptation, also to the additional vibration stimulus, on the neuromuscular level after 5 days of daily training. **References** Rittweger J (2010). ## THE EFFICACY OF A WHOLE-BODY, SELF-PACED INCREMENTAL TEST TO MEASURE MAXIMAL OXYGEN UPTAKE

MAUGER, A.R., METCALFE, A.J., SCULTHORPE, N., CASTLE, P.

UNIVERSITY OF BEDFORDSHIRE

The traditional maximal incremental exercise test to exhaustion (MIE) as a measure of maximum oxygen consumption ( $VO_{2max}$ ) is the most widely used exercise test in exercise science. Although the basic design varies, the generic principle is that a pre-set protocol forces a linear, incremental increase in work rate until the subject cannot maintain the required intensity (volitional exhaustion). It has been suggested (Noakes, 2008) that this protocol produces an 'unnatural' form of exercise that disregards three key tenets of 'natural' self-paced or freely chosen exercise: 1. Because the test endpoint is unknown, an 'open-loop' form of exercise is created, where it is impossible effectively regulate work rate in an anticipatory manner and thus construct an appropriate pacing strategy; 2. The fixed incremental work rate is not observed in endurance sports (where  $VO_{2max}$  is considered an indicator of performance); 3. The only control the subject has over intensity is to stop (volitional exhaustion), thus adding a highly subjective and motivational element. A new, self-paced  $VO_{2max}$  protocol (Mauger & Sculthorpe, 2010) has previously been developed and tested in cycle ergometry, where a significantly higher  $VO_{2max}$  was observed when compared to a traditional MIE protocol. This new, self-paced protocol uses incremental 'clamps' on the RPE scale, allowing work rate to vary, which creates a closed-loop form of exercise and addresses those concerns stated by Noakes (2008). Although perceptually regulated exercise tests have been used previously in estimating  $VO_{2max}$  (Eston et al., 2006), self-paced protocols

have never been used to directly test maximal oxygen uptake. The present study tested the efficacy of the new, self-paced protocol in treadmill running and compared measured VO<sub>2</sub>max with a standard treadmill MIE. Significantly higher VO<sub>2</sub>max scores ( $p < 0.05$ ) were observed in the self-paced protocol, when compared to the traditional MIE, which supports previous findings in the use of this new method of VO<sub>2</sub>max testing. It has previously been shown that self-paced exercise is less of a physiological challenge to homeostasis than self-paced exercise of matched intensity, evidenced by a reduced [La] and core temperature (Lander et al., 2009). As these components have been suggested to inform putative central control mechanisms to regulate work rate, it may be that the self-paced exercise allowed by the new protocol increased participants' tolerance of exercise, which led to a higher incidence of achieving a 'true' VO<sub>2</sub>max. ### ENERGY EXPENDITURE IN SIDE STEPPING

YAMASHITA, D.1, SHINYA, M.2, FUJII, K.1, ODA, S.1

1: KYOTO UNIVERSITY (KYOTO, JAPAN), 2: UNIVERSITY OF ALBERTA (ALBERTA, CANADA)

**Introduction** Our preliminary study showed that there are three different gait patterns in side stepping; walk-like, run-like and gallop-like gait patterns. Walk-like pattern was preferably selected at low speeds, whereas gallop-like pattern was chosen at high speeds (run-like pattern was not normally performed). This study was aimed to answer why these gait patterns were preferred in side stepping. In forward locomotion, it has been shown that humans and other animals move in a way that minimize the cost of transportation (Alexander, 2001). We expected that the same principle can be applied to side stepping. To test this hypothesis, oxygen consumption was compared between walk-like, run-like and gallop-like side stepping on a treadmill. Methods Ten male participants were asked to step sideward on a treadmill. Each participant practiced in advance three gait patterns. Walk-like pattern has double support phase and no flight phase, run-like pattern has flight phase but no double support phase and gallop-like pattern has both of double support and flight phases. The treadmill speed was following; 2.0~4.5 km/h for walk-like pattern and 3.0~5.5 km/h for run-like and gallop-like patterns. Each speed had a duration of 2 min and VO<sub>2</sub> was measured for the last 1 min. Gait patterns and treadmill speed were randomly ordered. Results Walk-like pattern showed the smallest energy consumption at the speed of 3.5 km/h or less, for example, at the speed of 3.5 km/h, VO<sub>2</sub> was: walk-like pattern =  $21.8 \pm 3.3$ ; gallop-like pattern =  $25.3 \pm 3.2$ ; run-like pattern =  $27.1 \pm 2.0$  ml/kg/min. Whereas gallop-like pattern was the smallest at the speed of 4.5 km/h, for example, VO<sub>2</sub> was: walk-like pattern =  $28.7 \pm 2.3$ ; gallop-like pattern =  $27.4 \pm 3.4$ ; run-like pattern =  $28.8 \pm 3.0$  ml/kg/min. Run-like pattern required more energy than gallop-like pattern at any speed tested. Discussion Physiological energy expenditure can explain which type of side stepping is preferred. Walk-like pattern is the most efficient way of locomotion at low speeds and gallop-like stepping is economical at high speeds. Run-like pattern seemed to be a less efficient style than gallop-like pattern in sideward locomotion. During landing phase in any bipedal locomotion, legs must change downward momentum to upward and re-accelerate center of mass toward an intended direction. In gallop-like side stepping, the trailing leg absorbs downward momentum and the leading leg produces upward momentum. Also, the trailing leg produces propulsive force by kicking the ground. The observed efficiency of gallop-like side stepping might be explained by the appropriate role-sharing between the two legs. Reference Alexander R. (2001). *Nature*, 412, 591. Dawson T, Tailor C. (1973). *Nature*, 246, 313-314.

### 3 MINUTES STAGES ARE NOT SUFFICIENT TO OBTAIN STEADY STATE IN WALKING EXERCISE IN SEDENTARY MIDDLE-AGED MEN.

O'HAGAN, C.J., DE VITO, G., NEWSHOLME, P.N., BOREHAM, C.A.G.

UNIVERSITY COLLEGE DUBLIN

**Introduction.** Measures of steady state substrate use can be obtained from indirect calorimetry during constant load submaximal exercise. A protocol using 3 minute cycling bouts to measure substrate use has been validated for use in young, moderately trained males (Achten et al., 2002), but was shown to be invalid for older, sedentary subjects for whom a longer submaximal bout was required to obtain steady state (Bordenave et al., 2007). The aim of this study was to evaluate the use of the short-bout protocol in walking exercise, which is known to elicit higher rates of lipid oxidation than cycling exercise at matched intensities (Achten et al., 2003), and to determine whether the short bout protocol may be sufficient to obtain steady state at lower but not higher exercise intensities. Methods. 12 overweight, sedentary males (mean age 55.1 years, mean BMI 30.7 kg/m<sup>2</sup>) performed four 6-minute submaximal treadmill walking trials at intensities corresponding to 20%, 30%, 40% and 50% of their estimated VO<sub>2</sub>max, predetermined from an incremental treadmill test. Oxygen consumption (VO<sub>2</sub>) and respiratory exchange ratio (RER) were measured by expired gas analysis, with lipid oxidation calculated using a stoichiometric equation (Peronnet and Massicotte, 1991). Data from the 2nd and 3rd minute of each exercise bout (SHORT protocol) were compared to the 5th and 6th minute (LONG protocol). Results. The SHORT and LONG protocols showed strong correlations for VO<sub>2</sub> ( $r = 0.98$ ) and lipid oxidation ( $r = 0.73$ ), and moderate correlation for RER ( $r = 0.69$ ). However, when agreement between SHORT and LONG was tested with Bland-Altman analysis, SHORT underestimated VO<sub>2</sub> (mean underestimation of 57 ml/min) and RER (a mean underestimation of 0.06) and overestimated lipid oxidation (mean overestimation of 121 mg/min). There was a significant effect of exercise intensity on the magnitude of the discrepancy; increasing with exercise intensity for all three variables (one way ANOVA,  $p < 0.05$ ). This effect persisted when absolute values were normalized to relative percentage differences between measures from the SHORT and LONG protocols. Conclusion. A 3 minute protocol of constant load walking exercise at intensities corresponding to between 20% and 50% of estimated VO<sub>2</sub>max is not sufficient to reach steady state in middle aged, sedentary men. Furthermore, the magnitude of the difference between SHORT and LONG protocols for metabolic variables increases with exercise intensity. References. ## QUADRICEPS AND INSPIRATORY MUSCLES FATIGUE DURING CYCLE EXERCISE TEST IN THE HEALTHY MIDDLE-AGED MEN

CHIEN, M., CHANG, Y., WU, Y.

SCHOOL AND GRADUATE INSTITUTE OF PHYSICAL THERAPY

**Introduction** Whether the inspiratory muscles may fatigue during intense exercise and thereby become a limiting factor to exercise performance is still debated. Little was known about the inspiratory muscles and quadriceps fatigue during exercise in the middle-aged population. This study was aimed to determine whether quadriceps or inspiratory muscles fatigue or both occurred during maximal exercise test in the middle-aged population, and to compare the extent of inspiratory muscles fatigue to that of quadriceps. **Methods** Eleven healthy men aged 50.6 (SD: 5.7) years participated into this study. The activation patterns of diaphragm and vastus lateralis (VL) during incremental maximal cycling exercise test were studied by surface electromyography (sEMG) (EMG100A, Biopac Systems Co., CA). The electrodes were placed in the seventh or eighth intercostal space on the right side of the body at the midclavicular line for recording of diaphragm (Verin et al, 2002). The extent of fatigue characteristics were compared by determining the increase in root-mean-square (RMS) of sEMG data obtained simultaneously during exercise test. To compare the different RMS values among subjects, RMS values were normalised with respect to the maximal sEMG RMS values during maximal contractions at the baseline. **Results** We found that the RMS of both diaphragm and VL increased significantly with increasing exercise workload in both groups. However, the VL fatigued more than the diaphragm at the higher intensity of peak exercise. **Discussion** Dyspnea and leg fatigue were commonly limiting factors to exercise performance. Some studies reported that exercise-induced diaphragmatic fatigue in both sedentary and physically active adults (Mador et al, 1993; Perlovitch et al, 2007). On the other hand, some studies have reported that significant fatigue of quadriceps occurred without induction of diaphragm during cycling exercise (Fitting et al., 1991; Mador et al, 2000). The conflict findings might be due to different exercise types, intensities, assessment tools, and populations. **In conclusion**, this study demonstrated that both diaphragm and VL muscles experience fatigue with increasing exercise intensity in healthy middle-aged men. However, significant fatigue of the quadriceps muscle occurred than the diaphragm with increased exercise load during cycle exercise test. **References** Fitting JW. (1991). Eur Respir J, 4, 103-108. ## EFFECTS OF TRANSCRANIAL DIRECT CURRENT STIMULATION ON PERFORMANCE AND RATING OF PERCEIVED EXERTION DURING SUBMAXIMAL CYCLING EXERCISE

OKANO, A.H.1, FONTES, E.B.2, MOURA, I.S.C.1, MONTENEGRO, R.A.1, CYRINO, E.S.3, FARINATTI, P.T.V.4

1 LABORATORY OF INTEGRATIVE BIOLOGY OF EXERCISE, FEDERAL UNIVERSITY OF RIO GRANDE DO NORTE; 2 STATE UNIVERSITY OF CAMPINAS; 3 STATE UNIVERSITY OF LONDRINA; 4 STATE UNIVERSITY OF RIO DE JANEIRO

**Introduction** Transcranial direct current stimulation (tDCS) is considered a neuromodulatory intervention and that induces excitability changes in the human motor cortex. It has already been shown that tDCS can reduce fatigue and improve endurance time during isometric forearm exercise in healthy subjects. To date, the effects of tDCS on the development of the rating of perceived exertion (RPE) and performance during dynamic exercise have not been studied. Therefore, the aim of this study was to investigate the effect of tDCS on the time to exhaustion (TE) and the development of RPE during submaximal cycling exercise to volitional exhaustion in healthy women. **Methods** Eleven female [24.3(3.0) years] volunteered to participate in this study. During the first session, the subjects performed a maximal incremental exercise test to determine peak power output (PPO). On the second and third sessions, volunteers underwent the experimental procedures (anodal tDCS on left insular cortex (IC) or sham (placebo) condition for 20 minutes followed by cycling exercise at 60%PPO until volitional exhaustion). RPE was recorded every six minute of the test. **Results** TE was significantly higher for anodal tDCS [35.1(6.1) min] than the sham condition [28.7(8.3) min]. RPE gradually increased from start toward the end of exercise, with significant differences between anodal and sham conditions at six [9.6(1.2) vs 11.8(1.6)] , 12 [11.7(2.2) vs 14.0(2.1)], 18 [13.5(1.9) vs 16.0(2.5)], and 24 minutes [15.3(1.6) vs 17.3(1.5)] of the test, respectively. **Discussion** Our first important finding was that anodal tDCS applied to the left IC twenty minutes before exercise improved exercise performance during cycling exercise at 60%PPO by reducing the RPE. Since cerebral hypoxia exerts a large influence on maximal exercise performance, we can speculated that the anodal stimulation improved performance via an increased cerebral oxygen availability after the end of stimulation. Regarding the RPE, there is evidence that the IC is the main brain site responsible for the awareness of subjective feelings from the body. The left anterior IC is activated mainly by positive and affiliative emotional feelings while stimuli that activate the right anterior IC are generally arousing to the body (for example, pain). The findings of the present study showed the possibility of use the tDCS to improve performance and reduce the RPE during submaximal cycling exercise to volitional exhaustion.

## DISSOCIATION IN CHANGES IN EMG ACTIVATION DURING MAXIMAL ISOMETRIC AND SUBMAXIMAL LOW FORCE DYNAMIC CONTRACTIONS AFTER EXERCISE INDUCED MUSCLE DAMAGE

PLATTNER, K.1, BAUMEISTER, J.2, LAMBERTS, R.P.1, LAMBERT, M.I.1

1:UCT/MRC RESEARCH UNIT FOR EXERCISE SCIENCE AND SPORTS MEDICINE, DEPARTMENT OF HUMAN BIOLOGY, UNIVERSITY OF CAPE TOWN, SOUTH AFRICA. 2:INSTITUTE OF SPORTS MEDICINE, DEPARTMENT OF EXERCISE AND HEALTH,

**Introduction** Exercise induced muscle damage (EIMD) is characterized by muscle pain, symptoms of swelling, muscle shortening, increased serum creatine kinase activity, decreased force output and altered neuromuscular function (Armstrong et al 1991). The aim of this study was to determine how the symptoms of EIMD influence the neuromuscular recruitment patterns during maximal and submaximal isometric and submaximal flexion-extension movements. **Methods** Twenty-five right-handed males were recruited for this study, and were allocated to either a control (n = 13) or experimental group (n = 12). In contrast to the control group, the experimental group participated in an EIMD protocol of the elbow flexor muscles. Subsequently, muscle soreness, arm circumference, resting elbow angle, serum creatine kinase activity, muscle function and EMG activity during maximal voluntary contraction, isometric low force contraction and a submaximal flexion-extension protocol were monitored in both groups for up to 132 hours after the EIMD protocol. **Results** After the EIMD protocol, muscle pain scores in the experimental group peaked after 36 hours with serum creatine kinase activity peaking after 108 hours. Twelve hours after the EIMD protocol, EMG activity had decreased by 20% during a maximal voluntary contraction in the experimental group ( $X_2 = 21.70$ ,  $p = 0.001$ ) and decreased by a further 10% until the end of the study (132 hours after the EIMD protocol) ( $X_2 = 21.70$ ,  $p = 0.01$ ). In contrast, EMG activity during submaximal movement increased significantly during the last two seconds ( $s_2$ ,  $s_3$ ) of the

flexion (s2:  $H = 9.61$ ,  $p = 0.0019$ ; s3:  $H = 11.01$ ,  $p = 0.0009$ ) as well as the first two seconds (s4, s5) of the extension movement (s4:  $H = 8.00$ ,  $p = 0.0047$ ; s5:  $H = 4.05$ ,  $p = 0.0442$ ) from 12 hours after the EIMD protocol. Discussion Classical symptoms of EIMD (increased muscle soreness, swelling, muscle shortening and increased creatine kinase activity, decreased muscle function and force output) (Lambert et al., 2002; Prasartwuth et al., 2005) were observed in the experimental group. A dissociation in EMG response was found in the experimental group between the EMG response during maximal voluntary contraction (decrease) and during submaximal movements (increase). This dissociated EMG response suggests that central regulation influences the neural firing patterns and motor unit activity. References Armstrong RB, Warren GL, Warren JA. ### CAUSE OF THE FATIGUE DURING THE INTENSITY ABOVE MAXIMAL LACTATE STEADY STATE

PEINADO, A.B., DÍAZ, V., BENITO, P.J., ÁLVAREZ, M., ZAPICO, A.G., CALDERÓN, F.J.

UNIVERSIDAD POLITÉCNICA DE MADRID

CAUSE OF THE FATIGUE DURING THE INTENSITY ABOVE MAXIMAL LACTATE STEADY STATE Peinado, AB1; Díaz, V2; Benito, PJ1; Álvarez, M2; Zapico, AG3; Calderón, FJ1 1: Facultad de Ciencias de la Actividad Física y del Deporte – INEF, Universidad Politécnica de Madrid (Spain). 2: Institute of Veterinary Physiology, University of Zürich (Switzerland). 3: Facultad de Educación, Universidad Complutense de Madrid (Spain). Introduction The maximal lactate steady state (MLSS) intensity corresponds to the transition between aerobic and anaerobic metabolism (1) and it is defined as the highest intensity where blood lactate concentration ( $[La]$ ) is maintained stable (2). The factors that influence the time to exhaustion at MLSS are still unclear (3,4). Therefore, the aim of the present study was to compare the physiological responses during cycling performed at MLSS and above MLSS (>MLSS), in an attempt to elucidate which factors are responsible of fatigue at this stage. Methods Twelve male amateur cyclists participated in the study ( $21 \pm 2.6$  years;  $179.8 \pm 7.5$  cm;  $72.2 \pm 9$  kg). Each subject performed an incremental test until exhaustion and two 30 min constant load tests to determine MLSS and >MLSS. MLSS was defined as the highest workload that could be maintained with an increase in  $[La]$  lower than  $1.0 \text{ mmol} \cdot \text{L}^{-1}$  during the final 20 min of the tests (2,3). Cardiorespiratory and blood parameters were measured throughout the tests. Two way ANOVA with repeated measures was used to determine differences between MLSS and >MLSS. The significant level was set at  $\alpha \leq 0.05$ . Results The power output at MLSS and >MLSS was  $280 \pm 28 \text{ W}$  ( $81.8 \pm 7\% \text{ VO2max}$ ) vs.  $297 \pm 29 \text{ W}$  ( $87.3 \pm 7.7\% \text{ VO2max}$ ). Due to exhaustion, only three cyclists were able to complete the 30 min at >MLSS test. There were not significant differences between MLSS and >MLSS tests in cardiorespiratory variables, except in oxygen uptake and ventilation at 30 min. The acid-base response was similar between the two intensities respect the pH values at 30 min ( $7.35 \pm 0.03$  vs.  $7.33 \pm 0.05$ , for MLSS and >MLSS respectively), however we found significant differences in  $[La]$  at 30 min:  $3.80 \pm 0.75$  vs.  $6.85 \pm 2.37 \text{ mmol} \cdot \text{L}^{-1}$ , for MLSS and >MLSS respectively. Discussion Despite there were no differences in cardiorespiratory variables and pH response between the end of MLSS and >MLSS tests, fatigue occurred in 75% of the subjects. Related studies have shown that exhaustion at MLSS appears whilst homeostasis is still maintained, according to the central governor model (3). The similar response between MLSS and >MLSS does not explain the cause of the fatigue at >MLSS and therefore there is an open question concerning why most of the cyclist are not able to maintain exercise performance at >MLSS. ### THE EFFECT OF MODERATE DEHYDRATION ON STRENGTH AND FATIGUE OF SKELETAL MUSCLE

TAMMAM, A.H., THOMPSON, M.W., PÉRIARD, J.D.

FACULTY OF HEALTH SCIENCES, UNIVERSITY OF SYDNEY, AUSTRALIA

Introduction There are conflicting reports as to whether moderate dehydration impairs muscle function (decreased strength and increased fatiguability). This may be due to many studies not isolating dehydration from confounding influences such as hyperthermia and fatigue, or it could be that subjects could not or would not fully activate the muscle. This study investigated the effect of moderate dehydration (~3% bodyweight deficit through sweating) induced by exercise-heat exposure on strength and fatigue of skeletal muscles. Methods Nine physically fit men (mean  $\pm$ SD: age,  $27.8 \pm 5.3$  yr; height,  $182.7 \pm 7.1$  cm; weight,  $79.4 \pm 10.0$  kg) had their body weight and muscle function determined over 3 consecutive days (familiarization-baseline period). Muscle function tests were (1) maximal voluntary isometric contraction (MVIC) of the quadriceps (dominant leg) with a brief superimposed electrical stimulus (TES). (2) fatiguability of the quadriceps (non-dominant leg) with 15 repeated MVICs (3sec contraction - 2sec rest) and TES applied on the 1st, 5th, 10th and 15th contraction, (3) hand grip flexor strength (dominant hand). These tests were undertaken pre-post prolonged treadmill walking that elicited a 3% loss of weight. This bodyweight deficit was maintained overnight (16-18 hrs) and the tests were repeated the following morning (EXP). The strength/fatiguability tests were also undertaken without the dehydration protocol (control trial- CONT) within 1-3 weeks with the order of dehydration and control trials randomized. Results - There was no change in the force production of the dominant leg for any of the conditions ( $p > 0.05$ ) - The handgrip strength was lower during the experimental condition than the control ( $F(1, 8) = 11.5$ ,  $p < 0.05$ ) with no difference in the time of test ( $F(2, 16) = 1.1$ ,  $p = 0.35$ ). - The force produced of non-dominant leg during the EXP condition was lower than that during CONT ( $F(1, 8) = 7.25$ ,  $p < 0.05$ ), the pre test was higher than both post tests ( $F(2, 16) = 7.19$ ,  $p < 0.05$ ) and as trial progressed the subjects force decreased ( $F(2, 16) = 29.3$ ,  $p < 0.05$ ). Discussion This study has shown that there is no significant effect of moderate dehydration on maximum strength of skeletal muscle, yet there was a significant effect of dehydration in increasing muscle fatiguability. Increased fatiguability may be due to an impaired sodium-potassium pump or impaired intracellular calcium regulation. References Adolph, E. F. (1947). Physiology of man in the desert. ### A NOVEL FIELD TEST TO DETERMINE CRITICAL VELOCITY

GALBRAITH, A., HOPKER, J., JOBSON, S., PASSFIELD, L.

UNIVERSITY OF KENT

Introduction Hinckson and Hopkins (2005) provide the only previous investigation into the reliability of Critical Velocity (CrV) and Anaerobic Running Capacity (ARC). Their study used constant velocity, run to exhaustion trials in which reliability is often poor (Laursen et al., 2007). By contrast, constant distance trials have shown greater reliability (Laursen et al., 2007), although due to the limitations of the manual speed control measures on standard motorised treadmills, these are best performed in a field based setting. Therefore, the aim of this study was to establish the reliability of CrV and ARC using a constant distance trial in the field. Methods Ten trained male middle distance

runners (age: 22±4yrs; VO<sub>2</sub>max 69.1±4.2ml.kg<sup>-1</sup>.min<sup>-1</sup>), completed a familiarisation trial plus three separate experimental trials on a standard 400 m athletics track. Three distances (3600, 2400 and 1200 meters) were used within each trial to achieve finishing times for the runs in the region of 3, 7 and 12 minutes. Participants were instructed to cover the set distance in the fastest time possible. Participants rested for 30 minutes between efforts. Distances were kept in the same order for all repeat-testing trials. Data were modelled using the linear distance-time model, described by the equation:  $d = (CrV \times t) + ARC$ , where:  $d$  = distance run and  $t$  = running time. Results Reliability data yielded a mean group typical error, expressed as a coefficient of variation (CV%) of 2.0% (95% confidence limit (95% CL): 1.4-3.8%) for trials 2-1 and 1.3% (95% CL: 0.9-2.4%) for trials 3-2. There was no significant difference in CrV across trials ( $P < 0.05$ ) and trial comparisons 2-3 fell within the 95% CI of the trial 1-2 comparisons. Based upon a CrV of 4.7m.s<sup>-1</sup> the limits of agreement are  $\pm 0.2$  to 0.5m.s<sup>-1</sup> of the measure for trials 2-1 and  $\pm 0.1$  to  $\pm 0.3$ m.s<sup>-1</sup> for trials 3-2. ARC proved to be less reliable with a group CV% of 18.4% (95% confidence limit (95% CL): 13.5-39.9%) for trials 2-1 and 9.8% (95% CL: 7.0-19.6%) for trials 3-2. Discussion The results of this study demonstrate that a novel constant distance field trial reliably assesses CrV and produces reliability data lower than have previously been reported using constant velocity trials (Hinckson and Hopkins, 2005). Although the assessment of ARC is less reliable, CV% are similar to those reported previously during laboratory-based testing (Hinckson and Hopkins, 2005). References Hinckson EA, Hopkins WG. (2005). *Med Sci Sports Exerc*, 37, 696. Laursen PB, Francis GT, Abbiss CR, Newton MJ, Nosaka K. (2007). *Med Sci Sports Exerc*, 39, 1374.

#### EFFECT OF TIME OF DAY ON MFO AND FATMAX DURING EXERCISE IN OBESE AND NORMAL WEIGHT WOMEN

TABARI, E.

GUILAN UNIVERSITY

**Introduction** Obesity has become a serious and growing public health problem. Previous ways to combat obesity have failed, and new approaches need to be taken (Wyatt, 2006). The biological clock regulates the expression and/or activity of enzymes and hormones involved in metabolism, and affect on substrate metabolism. Chwalibog et al. (2002) indicated that during day the major oxidative fuel is carbohydrate, while, during night changes in the energy status are accommodated by increasing fat oxidation. Therefore the purpose of this study was to determine the effect of time of day on maximal fat oxidation (MFO) and the exercise intensity at which the fat oxidation rate was maximal (Fatmax) during exercise in obese and normal weight women. **Material and methods** Twenty healthy, untrained (VO<sub>2</sub>max <50 ml/min/kg and less than three sessions per week of physical activity) women between the ages of 19 and 26 yr voluntarily participated in this study. Subjects include 10 obese (BMI >30 kg/m<sup>2</sup>) and 10 normal weight women (BMI 20-25 kg/m<sup>2</sup>). MFO measured during incremental running exercise test with 3 min stages on treadmill by indirect calorimetry method. Student's t-test and one-way ANOVA was used to analyses variables. **Results** In obese subjects, MFO (mg/min/kgFFM) in evening (8.54±1.5) was significantly higher than morning (8.01±1.2) ( $p \leq 0.05$ ). In addition, in normal weight subjects MFO was significantly higher in evening (8.9±1.9) than morning (7.51±1) ( $p \leq 0.05$ ). Fatmax occurred at exercise intensity around 44.6 ± 6% and 40.9 ± 4.4% VO<sub>2</sub>max in obese and 49.9 ± 5.1% and 43 ± 5.9% VO<sub>2</sub>max in normal weight groups in the evening and morning respectively, and it was significantly higher in evening than morning in both groups ( $p \leq 0.05$ ). We found that fat oxidation rates (mg/min/kgFFM) at 60%, 70% and 80 % VO<sub>2</sub>max in the morning and in the evening in normal weight group were significantly higher than obese group ( $p \leq 0.05$ ). **Conclusion** Our data suggest that Fatmax occurred around 44.6 ± 6% and 40.9 ± 4.4% VO<sub>2</sub>max in obese and 49.9 ± 5.1% and 43 ± 5.9% VO<sub>2</sub>max in normal weight groups in the evening and morning, respectively. Fat oxidation was similar in obese and normal weight women at exercise intensity lower than 60% VO<sub>2</sub>max and tended to be higher in normal weight than obese for exercise intensity higher than 60% VO<sub>2</sub>max. At all exercise intensity, fat oxidation rates were higher in the evening than morning. Thus we suggest that exercise in the evening with Fatmax intensity is better for weight loss purposes in obese and normal weight women. **References** Chwalibog, A, Thorbek, G. (2002). #### EVIDENCE FOR REDUCED NEUROMUSCULAR FUNCTION IN MEN WITH A HISTORY OF ANDROGEN DEPRIVATION THERAPY FOR PROSTATE CANCER

GIRARD, D., CANNON, J., MARINO, F.E.

CHARLES STURT UNIVERSITY

**Introduction** Research indicates that men with a history of androgen deprivation therapy for the treatment of prostate cancer (PCa+ADT) experience reductions in muscular strength and non-osseous fat free mass. It remains unknown if the decrease in muscular strength is primarily related to losses in muscle quantity or if a decline in muscle quality is also apparent. This cross-sectional study compared muscular strength and non-osseous fat free mass and the relationship between these measures in men with ADT for the treatment of prostate cancer and asymptomatic matched men. **Methods** Nine subjects (63-83 yr) with a history of prostate cancer and ADT treatment for a minimum of 6 mo (PCa+ADT) and 11 asymptomatic matched eugonadal men (HM; 59-80 yr) were assessed for prostate specific antigen (PSA) and total testosterone (TT). Total body (TBLM) and right thigh non-osseous fat free mass (RTLTM) were assessed using dual-energy x-ray absorptiometry. Peak torque of the right knee extensors at 0°/s (ISO) and 60°/s (CON) were assessed and ISO and CON per unit-mass of RTLTM were also calculated. Data were analysed using a multivariate ANOVA with a bonferroni correction and linear regression analysis with significance set at  $P \leq 0.05$ . **Results** Age, height, mass, body mass index, and prostate specific antigen were comparable between groups ( $P > 0.05$ ) while TT was lower in PCa+ADT ( $P < 0.01$ ). TBLM and RTLTM were similar between groups ( $P \geq 0.075$ ); however, absolute ISO and CON as well as ISO and CON per unit of RTLTM were lower for PCa+ADT ( $P < 0.05$ ). Linear regression analysis revealed significant relationships between TBLM and ISO ( $r^2 = 0.48$ ;  $P < 0.01$ ), TBLM and CON ( $r^2 = 0.42$ ;  $P < 0.05$ ), and RTLTM and CON ( $r^2 = 0.48$ ;  $P > 0.05$ ) in HM; however, comparable relationships were not observed in PCa+ADT ( $P > 0.05$ ). **Conclusion** These data indicate that men receiving ADT for the treatment of prostate cancer for a minimum of 6 months experience reductions in muscular strength and non-osseous fat free mass. Furthermore, the reductions in muscular strength were associated with declines in muscular quality rather than quantitative changes in muscle mass alone. These findings suggest that muscular strength is associated with a decline in neuromuscular function possibly due to reduced neural drive, altered muscle architecture, and/or impaired contractile function. Further research is

needed to identify the specific neuromuscular mechanisms contributing to the accelerated loss in muscular strength associated with ADT+PCa and determine if exercise is an effective intervention for these deleterious changes.

### ENERGY EXPENDITURE DURING SPORTING ACTIVITIES IN TRANSPLANT RECIPIENTS

TOTTI, V.1, ROI, G.S.1, MOSCONI, G.2, NANNI COSTA, A.3, STEFONI, S.2.

1: ISOKINETIC MEDICAL GROUP, EDUCATION AND RESEARCH DEPARTMENT (BOLOGNA, ITALY), 2: NEPHROLOGY, DIALYSIS AND RENAL TRANSPLANT UNIT, UNIVERSITY HOSPITAL ST. ORSOLA (BOLOGNA, ITALY), 3: ITALIAN NATIONAL

**Introduction** Transplant recipients show a reduction in maximal exercise capacity and cardio-respiratory fitness that may be counteracted by physical and sporting activities (Nielsen et al. 2001). The aim of this study was to contribute to the debate about sporting activity and transplantation by presenting metabolic data collected "on the field". **Methods** The energy expenditure during some sporting activities (leisure and competitions) was measured by Sensewear Armband (Bodymedia, USA) in 48 males (age  $48 \pm 13$  yrs; BMI  $24.1 \pm 2.7$  kg.m<sup>-2</sup>) and 9 females (age  $42 \pm 13$  yrs; BMI  $24.0 \pm 3.0$  kg.m<sup>-2</sup>) transplanted patients (heart transplant n=3; liver n=12; bone marrow n=8 and kidney n=34), participating in various winter (alpine and cross country skiing) and summer (cycling, football, trak-&-field, trekking) sporting activities and competitions. Male and female patients had undergone transplantation  $9 \pm 6$  (range 1-23) years and  $9 \pm 4$  (range 2-16) years before the study. The immunosuppressive regimens were being provided according to the institutional standard protocols. Results Patients were involved in sporting activities at intensity higher than 3 METs from  $74 \pm 30$  (football) to  $455 \pm 97$  (trekking) minutes. During sporting activities the mean ( $\pm$ SD) energy expenditure was  $327 \pm 70$  kcal.h<sup>-1</sup> in males and  $266 \pm 35$  kcal.h<sup>-1</sup> in females ( $t=4.784$ ;  $P<0.001$ ). The higher energy expenditure was attained by male football players during a match ( $412 \pm 55$  kcal.h<sup>-1</sup>) and the lower energy expenditure was attained by females trak-&-field ( $259 \pm 38$  kcal.h<sup>-1</sup>). **Discussion** Transplants recipient who practice sports activities are able to express a normal exercise capacity. The levels of physical activity and of daily energy expenditure are able to reduce risk factors potentially modifiable for cardiovascular disease (obesity, sedentary lifestyle, glucose and fat dysmetabolism) in a population that remains at high risk for vascular events (vascular calcifications, medical history prior to transplantation, side effects of immunosuppressive therapy). These patients represent the upper limit of performance currently available for transplant patients and in any way can not be considered representative of the performance of all the transplant recipients population. However, data collected on patients who practice sports activities can help us to understand their potential performance and thus to promote physical activity for all the transplant patients. **References** Nielsen H, Lejeune TM, Lalaoui A, Squifflet JP, Pirson Y, Goffin E. (2001). Nephrol Dial Transplant, 16, 134-40.

### A SINGLE SESSION OF ENDURANCE OR RESISTANCE TYPE EXERCISE SUBSTANTIALLY REDUCES THE DAILY PREVALENCE OF HYPERGLYCEMIA IN TYPE 2 DIABETES PATIENTS.

VAN DIJK, J., MANDERS, R.J.F., HARTGENS, F., VAN LOON, L.J.C.

MAASTRICHT UNIVERSITY MEDICAL CENTRE

**Introduction:** Postprandial hyperglycemia represents a strong and independent risk factor for the development of cardiovascular complications in type 2 diabetes. Regular exercise forms an effective strategy to improve glycemic control. Although the acute effects of endurance type exercise on glycemic control have been well established, the effects of resistance type exercise on blood glucose homeostasis remain largely unexplored. The present study compares the impact of endurance versus resistance type exercise on subsequent 24 h blood glucose homeostasis in various type 2 diabetic subpopulations. **Methods:** Fifteen impaired glucose tolerant subjects (IGT), 15 type 2 diabetes patients treated with oral blood glucose lowering medication only (OGLM), and 15 type 2 diabetes patients using exogenous insulin (INS) were recruited to participate in a randomized crossover experiment. All subjects were studied on 3 occasions for 3 days under strict dietary standardization, but otherwise free-living conditions. During an experimental period, subjects performed either a 45 min resistance type exercise session (at 75% of 1-Repetition Maximum), a 45 min endurance type exercise session (at 50% Wmax), or no exercise at all. Glucose homeostasis was assessed over the subsequent 24 h period by ambulant continuous glucose monitoring. **Results:** Despite the continued use of glucose lowering medication and the consumption of a healthy diet, subjects experienced excessive hyperglycemia (blood glucose  $>10$  mmol/L) throughout a considerable part of the day. In fact, hyperglycemia was prevalent for as much as  $2:11 \pm 0:37$ ,  $9:01 \pm 1:39$  and  $8:16 \pm 1:44$  h:mm (over 24 h) in the IGT, OGLM and INS group, respectively. Overall, the prevalence of hyperglycemia was reduced by  $35 \pm 7$  and  $33 \pm 11\%$  over the 24 h period following a single session of resistance and endurance type exercise, respectively (main effect  $P<0.001$ ). No differences were observed between the glucose lowering effects of resistance versus endurance type exercise. **Conclusion:** A single session of resistance or endurance type exercise substantially reduces the prevalence of hyperglycemia throughout the day in glucose intolerant men, insulin treated, and non-insulin treated type 2 diabetes patients. Both resistance and endurance type exercise should be integrated in exercise intervention programs designed to prevent and treat type 2 diabetes.

### MAXIMAL FAT OXIDATION AT THE DIFFERENT EXERCISE INTENSITY IN OBESE AND NORMAL WEIGHT MEN IN THE MORNING AND EVENING

AZIZI, M.

GUILAN UNIVERSITY

**Introduction** Daily light-dark cycle governs rhythmic changes in the behavior and physiology of most species (Froy, 2010). The performances, substrate oxidation as well as the effects of physical exercise are known to depend on the time of a day when the exercise is performed (Yujiro et al. 2006). Also, human studies indicate that heart rate, Gastric emptying, gastro-intestinal enzyme activity, all peak at certain times during the day. Also body temperature, oxygen consumption (Weinert & Waterhouse, 2007) and catecholamine levels are peaked in the afternoon. We hypothesize that change in these variables can alter the substrate oxidation. Therefore, the objectives of the present study were to determine maximal fat oxidation (MFO) and the exercise intensity at which the fat oxidation rate was maximal (Fatmax) at a different exercise intensity in obese and normal weight men in the morning and evening. **Methods** MFO was measured in 12 normal weight (BMI 20-25 kg/m<sup>2</sup>; VO<sub>2</sub>max  $45.7 \pm 3.44$  ml/min/kg) and 10 obese (BMI  $>30$  kg/m<sup>2</sup>; VO<sub>2</sub>max  $37.2 \pm 3.6$  ml/min/kg) men during incremental running exercise test with 3 min stages on the treadmill (Achten et al. 2002). Breath-by-breath measurements were taken during exercise by using an open circuit gas analysis system (COSMED, Quark b2, s.r.l. Rome, Italy). **Results** We found that fat oxidation rates and energy expenditure in both groups in the evening were higher than morning; there were no significant differences in MFO between obese and normal groups. Furthermore, the fat oxidation rate in low intensity exercise ( $<60\%$  VO<sub>2</sub>max) was similar in obese and normal weight groups, but in high exercise intensities, in normal weight men were significantly higher than obese men. Energy expenditure at all exercise intensities in the evening was higher than morning in both groups. **Conclusion** Our data show that in

obese men, MFO in the evening was significantly higher than morning. In addition, in normal weight men MFO was significantly higher in the evening than morning. Fat oxidation rates were similar in obese and normal weight men at the exercise intensity lower than 60% VO<sub>2</sub>max and tended to be higher in normal weight than obese men for exercise intensity higher than 60% VO<sub>2</sub>max. Also, at all exercise intensities, fat oxidation rates were higher in the evening than morning. Thus we suggest that independent of exercise intensity and body fat mass, exercising in the evening is more effective on fat oxidation and decrease body fat mass; therefore, it is better for weight loss purposes in obese and normal weight men. ### PHYSICAL ACTIVITY ADVICE IN GERMAN PRIMARY HEALTH CARE: ANALYSES IN A COHORT OF COMMUNITY-DWELLING ELDERLY

MOSCHNY, A.1, PLATEN, P.1, KLAABEN-MIELKE, R.2, TRAMPISCH, U.1, THIEM, U.3, HINRICHS, T.1

1: UNIVERSITY OF BOCHUM, 2: UNIVERSITY OF BOCHUM, 3: UNIVERSITY OF BOCHUM

**Introduction** Previous studies repeatedly indicated that most elderly people fail existing physical activity (PA) recommendations. For inactive people in old age, a physician's advice seems to be an important requirement to take up PA. The primary health care setting might thus offer the chance to influence and to support older people to be regularly active. Currently, data concerning general practitioner (GP) advice on PA in Germany is missing. Therefore, the aim of this study was to evaluate the rate and characteristics of elderly patients receiving PA advice from their GP. **Methods** Within the 7-year follow-up telephone interviews of the getABI cohort (community-dwelling primary health care patients), participants were asked whether their GP had given them advice to be regularly physically active within the past 12 months. The interview also included socio-demographic variables, medical conditions, walking ability, history of falls and pain, number of GP visits, and amount of PA. **Logistic regression analysis** (unadjusted and adjusted for all covariables) was used to examine factors associated with receiving advice. Analyses comprised only complete cases with regard to the analysed variables. Results are expressed as odds ratios (OR) with 95% confidence intervals (95% CI). **Results** Out of 1,627 analysed patients (median age 77; range 72-93 years; 52.5% women), 534 (32.8%) stated that they had received advice to be regularly physically active. In the adjusted model, those more often receiving GP advice on PA were men (OR [95% CI] 1.34 [1.06-1.70]), those suffering from pain (1.43 [1.13-1.81]), coronary heart disease and/or myocardial infarction (1.56 [1.21-2.01]), diabetes mellitus (1.79 [1.39-2.30]) or arthritis (1.37 [1.08-1.73]), and those taking a high (>5) number of medications (1.41 [1.11-1.80]). **Discussion** The study revealed a relatively low rate of elderly primary care patients receiving GP advice on PA. GPs seemed to focus their advice on patients suffering from chronic medical conditions. There are likely many more patients who would benefit from advice. A number of barriers to GPs for counselling about physical activity have been reported: e.g. time constraints, lack of educational resources in PA counselling, preference of patients for drug treatment, and lack of reimbursement. Novel concepts are needed to overcome barriers to PA counselling in primary health care. The study was conducted within the research cooperation PRISCUS and funded by the German Federal Ministry of Education and Research (01ET0720).

### OVERWEIGHT AND UNDERWEIGHT DISTURBS NEUROMUSCULAR FUNCTION AND PROPRIOCEPTION

PASCHALIS, V.1,2, NIKOLAIDIS, M.G.1,2, THEODOROU, A.A.1,2, DELI, C.K.1,2, RASO, V.3, JAMURTAS, A.Z.1,2, GIAKAS, G.1,2, KOUTEDAKIS, Y.1,2,4

1: UTH (TRIKALA, GREECE), 2: CERETETH (TRIKALA, GREECE), 3: FMUSP (SAO PAULO, BRAZIL), 4: UW (WOLVERHAMPTON, UK).

**Introduction** Overweight is defined as an excessive fat accumulation due to imbalance of energy intake and energy expenditure (Suastika 2006) and is related to changes in body geometry and posture (de Souza et al. 2005). Regarding the underweight individuals, their deficient muscle mass results in musculoskeletal disorders (Mauch et al. 2008) which in turns may influence whole body physiology (Coin et al. 2000). Therefore, the aim of the present investigation was to compare proprioception of lean, overweight and underweight females at rest and after eccentric exercise. **Methods** Twelve lean, twelve overweight and eight underweight females performed an eccentric exercise session using their knee extensors of both lower extremities. Muscle damage and proprioception (position sense, reaction angle and force mismatch) were assessed in the dominant extremity up to 3 days post exercise. **Results** The results indicated that proprioception at rest of the lean individuals is superior to the other two groups. Additionally, a faster reaction angle in the overweight group and a slower reaction angle in the underweight group compared to the lean group was observed. After eccentric exercise, proprioception affected more in overweight and underweight groups compared to the lean group. **Discussion** Pre exercise position sense of the overweight participants was worse, compared to the lean, and this could be associated with over-increased body mass which may reduce control of postural stability (Brockett et al. 1997; Proske et al. 2004). However, the greater muscle damage of the overweight participants led them to produce greater disturbances in proprioception compared to their lean individuals after the exercise session. Regarding underweight participants, their reduced muscle mass (Mauch et al. 2008) and their limited strength output led them to worse pre exercise position sense as well as to greater disturbances in proprioception after eccentric exercise compared with their lean counterparts. **References** Brockett C, Warren N, Gregory JE, Morgan DL, Proske U. ### THE EFFECT OF BODY FAT PERCENTAGE ON MAXIMAL FAT OXIDATION RATES IN YOUNG WOMEN

BLAIZE, A.N., POTTEIGER, J.A.

MIAMI UNIVERSITY

**THE EFFECT OF BODY FAT PERCENTAGE ON MAXIMAL FAT OXIDATION RATES IN YOUNG WOMEN** Blaize, A.N., Potteiger, J.A. Miami University (Oxford, Ohio, USA) **Introduction** Identification of the exercise intensity that elicits the highest rate of fat oxidation (i.e. fat use as a fuel) would allow for the development of more accurate exercise prescriptions in training programs targeted towards the promotion of fat loss and weight loss. There is little existing research that examines how body composition affects substrate oxidation rates in women; therefore, the purpose of this investigation was to examine how body fat percentage affects the maximal fat oxidation rates of women. **Methods** Fifteen female subjects, between the ages of 20-31 years had their body composition assessed using air displacement plethysmo-

graphy. Each subject completed a treadmill graded exercise test, which ended when the subjects respiratory exchange ratio (RER) reached 1.0. Heart rate (HR), RER, volume of oxygen consumed (VO<sub>2</sub>), and volume of carbon dioxide expired (VCO<sub>2</sub>) were recorded every minute using a Parvo Medics metabolic measurement cart. The rate of fat and carbohydrate oxidation was determined using stoichiometric equations and appropriate energy equivalents. Results One-way analysis of variance was used to examine the effect of body fat percentage (low vs. high) on FAT oxidation and CHO oxidation. No significant differences in FAT oxidation or CHO oxidation were found between the low-percent and high-percent groups. To determine if body fat percentage was related to substrate oxidation, Pearson correlation analyses were conducted. Body fat percentage was not significantly correlated to FAT or CHO oxidation. Discussion Past research has shown that women who are classified as obese have higher fat oxidation rates than women who were classified as normal weight (Schutz et al.). These research findings indicate that the greater the fat availability in the body, the higher the fat oxidation rate. The results of this study conflict with previous research. There were no significant differences in fat oxidation or carbohydrate oxidation between the low and high body fat percentage groups. Additionally, body fat percentage could not be correlated to substrate oxidation. These findings indicate that body fat percentage does not affect how women utilize fat during exercise, which could help in the creation of exercise interventions that prevent weight gain and/or promote weight loss in young women. ### ASSOCIATIONS BETWEEN INSULINE-LIKE GROWTH FACTOR-2 AND BMI IN HUNGARIAN ATHLETES

SZENDREI, B., PROTZNER, A., UDVARDY, A., TRAJER, E., BOSNYAK, E., KOMKA, ZS., SZMODIS, M., SZOTS, G., GYORE, I., TOTH, M.

SEMELWEIS UNIVERSITY FACULTY OF PHYSICAL EDUCATION AND SPORT SCIENCES

Introduction Sportgenomics is a new and promising field in sport sciences. Hundreds of genes were identified in connection with sport performance. In international studies IGF2 Apal polymorphism shown to be associated with antropometric parameters like BMI or fat free body mass. IGF2 plays a role in mammalian growth, influencing foetal cell division and differentiation, possibly metabolic regulation and muscle regeneration. Method We examined 108 athletes (51 men, 57 women, mean of ages: 23,5 years) from different sports. DNA was extracted from blood samples using DNA isolating Kit. PCR detections were done with Agilent 2100 Bioanalyzer in GenolD Laboratory. Body weight was measured by using medical scale. BMI was counted as weight/ height<sup>2</sup>. Statistical analysis was done by Statistica 7 program, using ANOVA, the level of significance was determined at 5%. Results In the whole sample we had 8 (7,4%) A/A, 44 (40,7%) A/G, 56 (51,9%) G/G. Means of the parameters in the 3 genotype groups were the following: A/A height 1,71, weight 63,4, BMI 21,5, A/G height 1,78m, weight 73,5kg, BMI 18,1, GG height 1,76, weight 67,3, BMI 21,8. The analysis of variance showed significant difference between the 2nd and 3rd groups, A/G and G/G in BMI (p=0,008). We found no difference between the groups comparing body fat. Discussion The genotype frequencies were similar to the international results (10% A/A, 35% A/G, 55%). Weight and BMI values were also lower in A/A genotype groups compared to A/G, G/G groups. Though in this research we got statistically significant results, all sportgenomical studies should be extended for more genes, investigating complex gene patterns and involving more antropometric, biomechanical parameters. ### EFFECTS OF RAPID WEIGHT LOSS AND WEIGHT REGAIN ON SLEEPING METABOLIC RATE, DIET-INDUCED THERMOGENESIS AND SUBSTRATE OXIDATION

SAGAYAMA, H.1, YOSHIMURA, E.1, YAMADA, Y.2, SHUTO, T.2, HIGAKI, Y.2, KIYONAGA, A.2, TANAKA, H.2

FUKUOKA UNIVERSITY

Introduction Athletes participating in sports with specific weight categories often compete at 5–10% below their habitual body weight (BW). Resting and sleeping metabolic rate (SMR) can be reduced in response to a loss of fat mass (FM) or fat-free mass (FFM) during rapid weight loss (1). It is unclear whether diet-induced thermogenesis (DIT) and substrate oxidation are also affected by rapid weight loss. Although prior studies suggested that regained weight is composed predominantly of FM (2), it is unknown what effects acute (~24 hour) weight regain after rapid weight loss has on SMR, DIT, and substrate oxidation. The present study examined the effect of rapid weight loss and weight regain on SMR, DIT and substrate oxidation. Method This study evaluated six healthy young male athletes who had experienced rapid weight loss (~5%BW) and weight regain. Each participant's body composition and metabolic rate were evaluated at three time points; 1 week before acute weight loss (baseline (BL)), the day after 7 days of weight loss (WL) and the day after acute weight regain (WR). The FM, FFM and total body water (TBW) were estimated by underwater weighing and 2H and 18O dilution methods. The SMR was measured in an indirect human calorimeter room (for five hours, 00:00 to 05:00). After an overnight fast, DIT was measured in the athletes for 2 hours after they ate the same meal in the chamber (07:00 to 09:00). Results Compared with BL, the BW, FM, FFM, and TBW were significantly decreased after weight loss (-4.2, -1.4, -2.8 and -1.9 kg, respectively). During the WG, FFM and TBW were regained (+2.7 and +2.2 kg, respectively) to a level not significantly different from BL. In contrast, FM was slightly increased during the WG period (+0.6 kg) but remained significantly lower than at BL. DIT (kcal) was not significantly changed. However, compared with BL, carbohydrate oxidation of the DIT component was significantly decreased at WL, and regained at WG (896, 432, 893 kcal/day, respectively). In contrast, lipid oxidation of the DIT component was significantly increased at WL (-194, 252, -219 kcal/day, respectively). Discussion During the WL period, DIT carbohydrate oxidation was inhibited while lipid oxidation was augmented. The FM was not regained to BL levels during the WG period, but LBM and TBW were rapidly increased over a 24-hour period. Although the underlying mechanism has not yet been elucidated, glycogen depletion followed by supercompensation, and the dehydration–rehydration process are possible mechanisms. ### BODY COMPOSITION, MUSCLE STRENGTH AND FITNESS FOR PERITONEAL DIALYSIS PATIENTS WITH CHRONIC RENAL FAILURE

RAIMUNDO, A.1,2, CHARRUA, Z.1, TOMÁS-CARÚS, P.1,2, BATALHA, N.1

UNIVERSITY OF ÉVORA, PORTUGAL, 2:HEALTH SCIENCE AND TECHNOLOGY RESEARCH CENTRE

Introduction It is common for patients with chronic renal failure (CRF) to have frequent complaints of low aerobic capacity, muscle weakness and chronic fatigue. The present body of evidence indicates that patient outcome is compromised if total Kt/V is below 1.7 (Lo, 2003;

Yao et al., 2001). An adequacy of weekly peritoneal creatinine clearance (CCr) above 60 L/1.73 m<sup>2</sup> is also suggested (Paniagua et al., 2002). The purpose of this study was to characterize body composition and muscle strength in Dialysis Peritoneal patients (DP) in both genders. We also pretend to analyze the values of these variables considering the cut-offs created for adequacy variables. Methods The study involved 34 patients with DP, 21 men (age: 52.10 ± 11.11 years old) and 13 female (age: 40.92 ± 14.28). Body composition was assessed by bioimpedance (TANITA TBF 300) and by dual-energy X-ray absorptiometry (DEXA Hologic QR). Muscle strength was measured with Isokinetic Dynamometer (Biodex). We measured spontaneous physical activity with an accelerometer (Actigraph GT1M Actilife-2009) for 7 days. The amount of dialysis was given by Kt/V and Clearance of Creatinine (CCr). Cut-offs for Kt/V (1,7) and for CCr (60L/SEM. /1,73m<sup>2</sup>) were consider in our study. Results Males showed higher values on Body Mass Index (BMI), Lean Mass (LM), and Bone Mineral Density (BMD) and lower values on Fat Mass (FM) as in the general population. The analysis of dialysis peritoneal adequacy with the other variables shows a higher values on BMD, FFM, and isokinetic strength on elbow extension movement with KT/V values under 1,7. Discussion Ours results did not differ about the usually gender differences on the BMI, FFM, BMD and FM. The significant differences between groups lower and upper the cut-off value for Kt/V on body composition and strength, contradict previous studies that refer that inclusive survival was significantly lower in patients with a Kt/V of <1.7 (Lo, 2003; Yao et al., 2001). These results could be influenced by the fact that our sample included more male than female subjects (mean ± SD of man and women Kt/V were respectively 1,7 ± 0,5 and 2,04 ± 0,7). Even the current knowledge suggest that the values of Kt/V should be higher than 1.7, we recommend that others variables as body composition and strength should be used as adequacy for DP patients once these variables are common related with better level of health. ## INVESTIGATIONS INTO BODY COMPOSITION AND VITAMIN D STATUS IN UK PROFESSIONAL JOCKEYS

WILSON, G.

LIVERPOOL JOHN MOORES UNIVERSITY

Wilson, G1, Fraser, W.D2, Drust, B1, Morton, J.P1 and Close, G.L1 1. Liverpool John Moores University, Liverpool, UK 2. University of Liverpool, Liverpool, UK Investigations into body composition and vitamin D status in UK professional jockeys Introduction - The nutritional practices of professional jockeys generally involve a low calorie diet, poor food choices and a reliance on sauna's to 'make weight' (Waldron-Lynch et al. 2010). Additionally, the common use of laxatives, appetite-suppressants, and forced vomiting has been reported (Leydon & Wall. 2002). However, there is a limited data available on the effects that such practices may have on body composition, vitamin D status and markers of ill-health in UK professional jockeys. Method - Eighteen professional UK based male flat jockeys were recruited for this study. All jockeys were required to visit the laboratory following an overnight fast to have a DXA scan for the assessment of body fat and bone mineral density, to give a venous blood sample for the assessment of vitamin D2 and D3 (25-OHD) using tandem mass spectrometry and to give a urine sample for the measurement of urine osmolality (UO). Data were compared with normative data using 1-sample T-tests. Results - Mean (SD) Age (years), Height (M) and Weight (Kg) for the 18 jockeys were 25 (3.7) 1.67 (0.05) and 56 (2.7) respectively. BMI (Kg/m<sup>2</sup>) was 20 (1.3) whilst mean body fat (%) was 13.5% (3.4). Mean urine osmolality (mOsmols/Kg H<sub>2</sub>O) was 820 (208). The mean BMD Z Score was -0.95 (0.49) significantly lower than normal (P<0.05) whilst 25-OHD (ng/ml) was 15.2 (12.7) significantly lower than normal (P<0.05). Discussion - Despite widespread reporting of dehydration techniques to 'make weight' the mean body fat was 13.5%, which is 3-5% higher than data reported in professional boxing (Morton et al. 2010). Mean BMD Z scores combined with low vitamin D concentrations suggests that the current dietary practices are having detrimental effects on bone health. Urine osmolality suggested severe dehydration. Conclusion - There is evidence that the dietary practices employed by UK professional jockeys tested here may be detrimental to optimal health and performance. With a combination of low vitamin D status, relatively high body fat and (self-report) lack of basic nutritional knowledge there is a need to educate these athletes on healthier ways to 'make weight' that could improve health and performance. #### SELF-ASSESSED TACTICAL SKILLS OF ELITE YOUTH SOCCER PLAYERS WITH DIFFERENT ACADEMIC ACHIEVEMENT

KANNEKENS, R., ELFERINK-GEMSER, M.T., VISSCHER, C.

HAN UNIVERSITY OF APPLIED SCIENCES / UNIVERSITY MEDICAL CENTER GRONINGEN

Self-assessed tactical skills of elite youth soccer players with different academic achievement Kannekens, R., Elferink-Gemser, M.T., Visscher, C. Center for Human Movement Sciences, University Medical Center Groningen, The Netherlands HAN University of Applied Sciences, Institute for Studies in Sports and Exercise, Nijmegen, The Netherlands Introduction A positive relationship has been established between sport performance and tactical skills (e.g., Kannekens et al., 2009; Williams et al., 1993) and between sport performance and academic achievement in elite youth athletes (e.g., Jonker et al., 2009; Umbach et al., 2006). Unknown, however, is whether elite youth athletes with different academic achievement score differently on tactical skills. Therefore, the aim of this study was to compare the self-assessed tactical skills of elite youth soccer players with different academic achievement. Methods The tactical skills inventory for sports (TACSIS; Elferink-Gemser et al., 2004) with questions related to declarative and procedural knowledge was used to measure self-assessed tactical skills of 93 elite youth soccer players (mean age 17.3±0.6) attending either pre-vocational (n=45) or pre-university (n=48) schools. Results Multivariate analyses of covariance with academic achievement as factor and field position and repeating class in school as covariates, revealed differences between elite youth soccer players attending pre-vocational and pre-university schools on the total construct of self-assessed tactical skills (p<.05) in favour of players at the pre-university schools. Discussion Pre-university students primarily learn to store knowledge pertaining to cognitive domains (Ministerie van OCW, 2008). In contrast, students attending pre-vocational schools primarily learn skills, which they have to apply in other situations (Ministerie van OCW, 2008). It is suggested that the

cognitive skills players acquire attending pre-university schools may help them or are consistent with declarative knowledge in sport situations (i.e., 'knowing what to do'). Regarding procedural knowledge (i.e., 'doing it'), no clear picture for its relation with academic achievement is derived from the results. ## EFFECTS OF AN ONE WEEK SOCCER-SPECIFIC HIGH INTENSITY INTERVAL TRAINING ON THE PERFORMANCE OF AMATEUR SOCCER PLAYERS

OESSEN, S., HINTERKÖRNER, F., HACKL, M., WESSNER, B., TSCHAN, H.

UNIVERSITY OF VIENNA

Purpose: This study aimed to analyze the effects of a soccer-specific high intensity interval training micro-cycle (SS-HIIT) on performance parameters, on stress recovery balance and biochemical damage and inflammation markers respectively. Methods: A training group (TG) consisting of 8 amateur soccer players completed 11 training sessions within 6 days, whereas no exercise training was performed by subjects of a control group (CG) (n=8). A battery of exercise performance tests (maximal exercise test on a treadmill; Yo-Yo intermittent recovery test level1 (Yo-Yo IRI); Running Anaerobic Sprint Test (RAST) and a 20-meter sprint test) were performed before the intervention and following SS-HIIT respectively. Blood samples were drawn before, as well as 3 and 7 days following the loading period and creatine kinase activity; myoglobin, interleukine 6, leptin, adiponectin, troponin and NT-proBNP were analyzed. Additionally the stress-recovery balance questionnaire (RESTQ-sport) was completed. Training was performed twice daily and consisted of 4 repeated bouts over 4 minutes performed with 95% of the HFmax. interspersed by 3 minutes of low-intensity periods performed with 70% of the HFmax each. These exercise bouts were organized with soccer-specific small-sided-games. Results: The study showed sign. improvements with regard to performance at the anaerobic threshold (p=0,011), to the running performance (Yo-Yo Intermittent Recovery Test, p=0,000), to the average performance of the RAST (p=0,001) and to the RAST fatigue index (p=0,008) in the TG without any changes in CG. Sprinting time however did not change significantly. No sign. elevations of the biomarkers compared to baseline data could be detected following 3 and 7 days of recovery in both groups. RESTQ-sport questionnaire showed an increased physical strain of the participants of the TG immediately following the intervention. Conclusion: These results underline the effectiveness of repeated interval training performed in a block micro-cycle in enhancing soccer-specific performance. Although players demonstrate an increased stress immediately following this intervention, biochemical markers used for the diagnoses of overtraining are not elevated following 3 and 7 days of passive recovery. Based on these results it seems that a high intensity endurance micro-cycle with two training sessions a day over a week is well tolerated by amateur soccer players.

## EVALUATION OF PLAYERS' ACTIVITY DURING AMATEUR PRESEASON SOCCER PERIOD

CONDELLO, G., MINGANTI, C., LUPO, C., CAPRANICA, L., TESSITORE, A.

UNIVERSITY OF ROME

Introduction Despite the widespread use of the performance monitoring in soccer, more information is available for elite players with respect to no-professional ones. Thus, the purpose of this study was to provide a motion analysis of trainings (TR) and friendly matches (FM) of an amateur soccer team during the 2010 preseason. Methods Although 22 players took part at preseason only 8 of them (age 26.2±3.3 yrs) were continuously monitored during all TR and FM by means of GPS devices (SPI Pro X, 15 Hz). The variable studied was the percentage of time spent in each one of the following 6 speed categories: standing (ST; 0-0.6 km•h<sup>-1</sup>), walking (W; 0.7-7.1 km•h<sup>-1</sup>), jogging (J; 7.2-14.3 km•h<sup>-1</sup>), running (R; 14.4-19.7 km•h<sup>-1</sup>), high-speed running (HSR; 19.8-25.1 km•h<sup>-1</sup>), sprinting (SP; >25.2 km•h<sup>-1</sup>). The different components of TR were classified in 5 categories: Small-sided-games (SSG), Situational (SI) and Tactical (TA) drills, Training matches (TM), and TM with adapted rules (TMR). A MANOVA for repeated measures was applied for FM analysis, while a descriptive statistics were used for TR analysis. Results The FM analysis showed that players spent meanly 3.4±1.8%, 65.8±8.0%, 25.0±6.8%, 4.7±2.1%, 0.9±0.5% and 0.1±0.1% of time per match for ST, W, J, R, HSR and SP, respectively. The multivariate analysis of FM indicated main effects for matches (p=0.014) and for halves (p=0.018). The univariate tests showed matches differences for ST (p=0.006) and HSR (p=0.014), while half differences were for ST (p=0.003), W (p=0.029), J (p=0.038), and R (p=0.028). The TR analysis indicated as players spent meanly 6.8±8.4%, 63.5±10.1%, 25.4±10.3%, 3.6±2.1%, 0.6±0.6% and 0.1±0.2% of time per TR for ST, W, J, R, HSR and SP, respectively. In particular, the SI showed the highest and lowest values for ST (28.6±8.5%) and W (58.1±6.8%) respectively, while TA, SSG and TM was less than 1% for HSR and SP. Discussion The FM analysis highlighted that players spent a reduced time at high-intensity running (R, HSR and SP), which could be explained by the amateur level, the preseason period and the nature friendly of the matches. Comparing our data with those of elite level (Bradley et al., 2010) they are similar for high-intensity, while the fatigue occurrence (Mohr et al., 2003) could explain the higher time spent in ST and W, and lower time in J and R registered during the second half. The TR analysis confirmed that players spent more time at low-intensity (ST, W and J) than at high-intensity running, while TM were the most related to reproduce the FM demands. ## THE NUTRITIONAL STATUS OF YOUNG ELITE SOCCER PLAYERS

ANDJELKOVIC, M.1, BARALIC, I.2, RADIVOJEVIC, N.1, DIKIC, N.1, DJORDJEVIC, B.2, VUJIC, S.1

1: SPORTS MEDICINE ASSOCIATION OF SERBIA (OUTPATIENT CLINIC VITA MAXIMA), BELGRADE, SERBIA, 2: INSTITUTE FOR BROMATOLOGY, FACULTY OF PHARMACY, BELGRADE, SERBIA

Introduction The condition of health and ability of athlete to compete both physically and mentally is influenced by the intake, absorption and utilization of nutrients and it is estimated through nutritional status (NS). Inadequate nutritional strategies can have negative impact on sports performance in endurance and energy demanding sport such is soccer. The aim of this study was to analyze NS of soccer players and correlate with blood, biochemical, anthropometric and ergospirometric parameters. Methods In this cross-sectional study 40 male elite soccer players completed 3-day dietary record at the beginning of training season. At the same time anthropometric measurement and ergospirometry test were conducted. Lipid status, hematological, biochemical, oxidative and anti-oxidative stress parameters were sampled from athletes as well. The fluid, energy, macronutrient and micronutrient intakes were calculated using COSMED FMed 2.0

software. Results Athletes had a mean age, height, weight, BMI and F% of  $16.7 \pm 0.7$  years,  $179.2 \pm 6.1$  cm,  $71.5 \pm 7.0$  kg,  $22.2 \pm 1.5$  and  $9.33 \pm 2.7$ , respectively. Daily energy intake (EI) was  $3042.9 \pm 905.9$  kcal which is significant lower ( $p < 0.001$ ) than the calculated values. EI was derived from carbohydrate, fat and protein by  $52\% \pm 8.2$ ,  $31.0\% \pm 5.5$  and  $17\% \pm 3.5$ . Fluid intake (ml) was very low  $1782.3 \pm 714.7$  and there is doubt about the validity of reported values. In terms of micronutrient intake, players had variation from DRI (%DRI) for Ca (71.6), Mg (94.8), Fe (134.5), K (71.2), Na (277.6), Vit.C (210.8), Vit.B6 (23.8) and Vit.B12 (61.1). Cholesterol (112.0) and saturated fatty (157.6) intake was above DRI. 22 players had iron deficiency without anemia ( $11.6 \pm 1.5$ ) that is already described in literature as a factor that can have impact on endurance. EI was positively correlated with Fe ( $p < 0.01$ ) and Ca ( $p < 0.05$ ) intake. F% demonstrate significant difference ( $p < 0.05$ ) for various soccer position in offense. The ANOVA showed that EI had significant effects on  $VO_{2max}$ . Discussion According to our and literature data, NS assessment of young soccer players suggests that they should increase EI together with a higher carbohydrate proportion. Research indicates that fluid and micronutrient intake is inadequate, so players should adopt dietary habits that ensure DRI. Interactions between EI and  $VO_{2max}$  clearly show that energy availability affects sports performance and this should be considered when training and nutritional strategies in soccer are planned. ## FOOTBALL, HEALTH AND HOMELESSNESS. THE COMPLEXITIES OF ENGAGING HOMELESS MEN IN REGULAR PHYSICAL ACTIVITY.

DUNN, K., DRUST, B., FLOWER, D., RICHARDSON, D.

LIVERPOOL JOHN MOORES UNIVERSITY

Introduction: At present, there are over 6,000 single homeless men living in England (Department for Communities and Local Government, 2010). Single homeless people have, on average, worse health than the population as a whole (Bines, 1994). Participation in regular recreational football can significantly improve the health of men (Krustrup et al., 2010). This study explores the biological, psychological and social effects of engaging homeless men in regular physical activity through a Football in the Community programme. Methods: 15 homeless men (mean  $\pm$  SD: age  $24.4 \pm 3.5$  years, height  $175.9 \pm 4.8$  cm, mass  $74.0 \pm 14.2$  kg) engaged in a 12 week programme consisting of 4 hours of football training per week. Indices of health (body composition, blood pressure and resting heart rate) were measured pre and post the intervention. The 1st author adopted a practitioner-cum-researcher role and was immersed in the planning and delivery of the programme. Social and psychological issues were discussed with participants through informal client-researcher interactions and data was collated through field notes and personal reflections. Results: Total % body fat and total fat mass decreased from pre ( $19.20 \pm 3.96$  % and  $16 \pm 8.5$  kg respectively) to post testing ( $18.25 \pm 5.02$  % and  $15.4 \pm 9.1$  kg). Lean mass increased from  $64.5 \pm 21.5$  kg to  $65.5 \pm 20.9$  kg, whilst blood pressure and resting heart rate decreased from  $130/84 \pm 20$  and  $82 \pm 30$  bpm respectively to  $123/78 \pm 5$  and  $76 \pm 27$  bpm. However, although 100% of participants reported that the programme had vast appeal to them, adherence to the complete programme was poor ( $n=2$ ) due to the complexities and irregular lifestyles of this population. Issues with transport, lack of motivation and poor health were common explanations for irregular and non attendance. Discussion: Adherence to a regular physical activity programme can pose a challenge to homeless, single men. Further research is required to explore the barriers and realities that homeless men face when attempting to engage in physical activity in order to design a programme that is likely to accrue greater health benefits through higher levels of adherence. ## RELATIONSHIP BETWEEN JUMP AND SPRINT ABILITY IN FOOTBALL PLAYERS OF DIFFERENT AGE

DA SILVA GRIGOLETTO, M.E., GÓMEZ-PUERTO, J.R., BENÍTEZ SILLERO, J.D., GUILLEN DEL CASTILLO, M.

JUNTA DE ANDALUCIA

Introduction The relationship between jump and sprint ability has been widely assessed, analyzing different jump types, and different sprint distances (Stolen et al., 2005). Lately, sprint distances of 5m and 30m have been widely used in football testing, so, the objective of the present study is to report reference values and to analyze the correlation of squat jump (SJ) and countermovement jump (CMJ) with sprint ability using such distances in three base categories of a Spanish professional football team. Methods A total of 102 players have been assessed from three categories: U15 (age:  $14.02 \pm 0.273$ ;  $N=36$ ), U16 (age:  $15.45 \pm 0.505$ ;  $N=37$ ), U18 (age:  $17.55 \pm 0.801$ ;  $N=39$ ), excluding the goalies. Training load was controlled during the two days prior to testing (two days before: light training, day before: no training). Jump ability (SJ, CMJ) was assessed by using a contact mat, and sprint ability (5m, 30m) by using three pairs of photo cells positioned at 0.5m from ground level. Both systems were connected to a laptop to collect data. All testing was performed in-season and when the coach deemed the players were at their best performance level. Data (mean $\pm$ SD), and correlation studies are presented. Results The values obtained for jump ability were the following for U15, U16, and U18: SJ ( $33.7 \pm 4.5$ cm,  $34.9 \pm 4.3$ ,  $38.6 \pm 3.3$ cm, respectively;  $p < 0.05$ ), and CMJ ( $37.1 \pm 4.5$ cm,  $37.1 \pm 4.9$ cm and  $42.5 \pm 4.1$ cm, respectively;  $p < 0.05$ ). With regards to sprint ability, the values obtained were: for 5m sprint ( $1.004 \pm 0.0481$ sec,  $0.984 \pm 0.501$ sec, and  $0.939 \pm 0.047$ sec, respectively;  $p < 0.05$ ), and for 30m sprint ( $4.454 \pm 0.36$ sec,  $4.285 \pm 0.213$ sec, and  $4.191 \pm 0.116$ sec, respectively;  $p < 0.05$ ). The correlation found between the 5m sprint and the jump testing was  $r = -0.566$  ( $p < 0.05$ ) for SJ and  $r = -0.551$  ( $p < 0.05$ ) for CMJ. Furthermore, the correlation found between the 30m sprint and the jump testing was  $r = -0.634$  ( $p < 0.05$ ) for SJ and  $r = -0.617$  ( $p < 0.05$ ) for CMJ. It was observed that, when analyzing each category separately, the correlation, although statistically significant in all categories, was stronger as we move up; therefore, correlation tends to be lower in U15 and greater in U18. Discussion The values presented show the evolution of jump and sprint ability, improving from the inferior category to the superior ones. The observed sprint values are in agreement with those reported in the literature while jump values are inferior and, thus, improvable. Moderate correlations were found between jump ability and sprint, increasing as players move up from one category to the following; from the results it can be derived that there is possibly greater influence of coordinative factors in the lower categories, losing influence as strength becomes more important over the years. ## 5 WEEK OF REPEATED SPRINT TRAINING CAUSE MODERATE EFFECT ON YO-YO IR1 AND 35M SPRINT TIME IN ADULT AMATEUR SOCCER PLAYERS

NYGAARD, O., OLSEN, A., INGEBRIGTSEN, J.

UNIVERSITY OF NORDLAND

Introduction Research indicates that the ability to perform high intensity running is important in soccer. Hence, it has been suggested that athletes in soccer can benefit from the inclusion of speed-endurance and high-intensity training (Iaia and Bangsbo 2010). Therefore, the aim of this study was to investigate the effect of repeated sprint training on repeated sprint ability (RSA) and Yo-Yo IR1 on adult amateur soccer players. Methods Fourteen male amateur soccer players (age  $22.7 \pm 3.1$  yrs, mass  $77.2 \pm 8.6$  kg, and height  $181 \pm 0.06$  cm) from Norwegian national level four, were tested in RSA (7x35m) and Yo-Yo IR1. These tests were conducted on two separated days. Further, the subjects were divided into one repeated sprint group (RS) and one contrast group (CG), both training twice weekly during team practices. The RS training consisted of 4 sets x 7 x 35m sprints with start every 30th second interspersed with 3 min active recovery between sets. The CG training consisted of four sets of 3.5 min. running with a ball in a specific "dribbling track", with 3 min. active recovery between sets. Differences between pre- to post-test were calculated using paired t-test. Possible between group differences in performance were tested by unpaired t test. Differences were considered significant at  $p < 0.05$  and results are presently expressed as mean  $\pm$  standard deviations (SD). Also, Cohen's d was calculated (Rosnow and Rosenthal 1996) to determine the effectiveness of the repeated sprint and contrast training. Results No significant changes were found in RSA, maximal speed or Yo-Yo IR1. However, improved (not significant) Yo-Yo IR1 performance was observed within both RSG ( $\sim 10\%$ , from  $1444 \pm 562$  to  $1590 \pm 342$  m) and CG ( $\sim 5\%$ , from  $1710 \pm 505$  to  $1800 \pm 512$  m). Based on the scale developed by Batterham and Hopkins (2006) we found a moderate effect on Yo-Yo IR1 ( $d = 0.34$ ) and 35m sprint time ( $d = 0.20$ ) and a trivial effect on mean 35m repeated sprint time ( $d = 0.06$ ) within the RSG. The contrast training within CG gave a moderate effect on 10m ( $d = 0.27$ ) and 35m ( $d = 0.59$ ) sprint time, as well as on mean 35m repeated sprint time ( $d = 0.40$ ), while only trivial effect on Yo-Yo IR1 ( $d = 0.19$ ). Discussion Present results indicate that 5 weeks of twice weekly repeated sprint training cause a moderate effect on Yo-Yo IR1 and 35m sprint performance. Although present changes were not found to be statistical significant, a 10% improvement in Yo-Yo IR1 performance could indicate an improved ability to perform high-intensity running in soccer matches. However, we speculate that to gain significant improvements, present players would need a longer period of systematic repeated sprint training as this was a new form of physical training for them. ## CHANGES IN HORMONAL CONCENTRATIONS AND BLOOD BIOCHEMISTRY OVER THE PRESEASON AND FIRST COMPETITIVE SOCCER MESOCYCLE IN STARTERS AND NON-STARTERS

PATRAS, K., GIANNITOPOULOS, T., SIARAVAS, S., EVAGGELOU, A., GEORGOULIS, A.D.

ORTHOPAEDIC SPORTS MEDICINE CENTER, UNIVERSITY OF IOANNINA

CHANGES IN HORMONAL CONCENTRATIONS AND BLOOD BIOCHEMISTRY OVER THE PRESEASON AND FIRST COMPETITIVE SOCCER MESOCYCLE IN STARTERS AND NON-STARTERS Kostas Patras<sup>1,3</sup>, Thomas Giannitopoulos<sup>3</sup>, Spyridon Siaravas<sup>3</sup>, Aggelos Evaggelou<sup>2</sup>, Anastasios D. Georgoulis<sup>1</sup>. 1Orthopaedic Sports Medicine Center, School of Medicine, University of Ioannina, Greece 2Laboratory of Physiology, School of Medicine, University of Ioannina, Greece 3F.C PAS Giannena 1966 INTRODUCTION: Soccer is a sport that is characterized by the application of a complex training nature thought out the season [1]. The ability of the bodily systems to adapt to composite stresses is influenced by the interaction between training and competition [1, 2]. Therefore the potential greater competitive responsibilities being placed on the regular starters in soccer may have a greater impact on the hormonal and biochemical response. The present study examined whether differences existed between starters (S) and non-starters (NS) professional soccer players over the course of the pre-season and first competitive mesocycle. METHODS: Twenty-one professional soccer players participated in the study. Blood samples were collected before the initiation of the preseason mesocycle (July, PRE), before the first competitive game (September, END-PRE) and at the end of the first competitive mesocycle (October, MESO 1). Samples were analyzed for haematocrit (HCT), haemoglobin (HGB), creatine kinase (CK), ferritin (FER), free testosterone (Free T) and cortisol (C). Players were divided as S (n=10) having played >75% of the total game time during MESO 1 (7 games) and as NS (n=11) having played <25% of the total game time. A two way ANOVA (group as between and time interval as within factor) with Tukey post-hoc analyses was used for statistical analysis. RESULTS: HCT was higher for both groups at MESO 1 and END-PRE than PRE ( $p < 0.001$ ), HCT was higher for both groups at MESO 1 and END-PRE than PRE ( $p < 0.001$ ), CK was lower for both groups at MESO 1 than END-PRE and PRE ( $p < 0.01$ ), FER was lower for both groups at MESO 1 and END-PRE than PRE ( $p < 0.001$ ), Free T was higher for both groups at MESO 1 than END-PRE and PRE ( $p < 0.001$ ) and C remained unchanged for both groups from PRE to MESO 1. DISCUSSION: The first seasonal competitive mesocycle does not induce significant differences in the hormonal and biochemical response of S soccer players compared to NS. Both groups adapt to the training loads by increasing Free T levels [3]. Additional stress from competitive games is not translated into an exacerbated C response [3]. Although increases in both HCT, HGB are observable after the end of the preparatory period, they occur in conjunction with reduced iron stores which may indicate that these positive changes will plateau or even decrease in the long term. ## RELATIONSHIP BETWEEN THE EXPERIENCED IMPACT OF FATIGUE AND PHYSICAL AND NERVOUS SYSTEM CHARACTERISTICS IN FOOTBALL PLAYERS

OLM, T., BASKIN, K., HERDE, K.

TALLINN UNIVERSITY

RELATIONSHIP BETWEEN THE EXPERIENCED IMPACT OF FATIGUE AND PHYSICAL AND NERVOUS SYSTEM CHARACTERISTICS IN FOOTBALL PLAYERS Olm, T., Baskin, K., Herde, K. Tallinn University (Estonia) Introduction The aim of the study is to find out which characteristics of physical and cognitive abilities are related to athletes' experienced impact of fatigue on their technical skills and will to fight. Methods The subjects were 21 male football players of the best club of Estonia (FC Flora). Their average age was  $20.5 \pm 2.8$  years. The test battery included anthropometric measurements, electro-, echo- and polycardiography, and incremental treadmill test to volitional exhaustion. Blood lactate concentration, maximum oxygen uptake, the anaerobic threshold were recorded. Anticipation speed and correctness, and ability to concentrate were assessed using the software WinPsycho 2000 (Thomson 2001). Before the treadmill test the athletes estimated how substantial is the impact of fatigue on their: a. technical skills; b. will to fight, giving grades from 0 to 3. The mean values of the indices and Pearson product moment correlation coefficients between physical indices, nervous system indices and the grades of the

experienced impact of fatigue were calculated. Results Most anthropometric indices, body fat, echocardiographic indices and indices characterizing anaerobic and aerobic metabolism have statistically significant correlations between themselves. But there are no correlations between them and the nervous system indices, except for the anaerobic threshold which has significant correlations with anticipation speeds. Anticipation speed, measured before and after treadmill test, alone has substantial correlations with athletes' esteem grade points of athletes. Discussion From the correlation analysis for all 42 average indices we can see that there is considerable variability in the relationships between the indices according to the different systems. The indices of physical abilities, while having numerous significant mutual correlations, have low correlations with the indices of the nervous system. In our earlier work (Olm et al., 2003) we observed tendencies towards correlations between the latter and the anaerobic metabolic indices. Here we found positive correlation between the anaerobic threshold and the anticipation speed. As anticipation speed has crucial importance for the perception of moving objects and is very sensitive to fatigue, it is understandable that these indices are related to players' subjective estimations of the impact of fatigue. Conclusions As football performance can be divided into many multidimensional performance characteristics (Elferink-Gemser, et al., 2004) the current results showed that complex investigations can be useful for identifying the players' performance level. References Thomson K.(2001).FEPSAK Bulletin,Vol 13, 2-7. Olm T, Thomson K, Baskin K, Herde K.(2003).Proc.8th Ann congr ECSS,224. Elferink-Gemser M. (2004). J Sports Sci, 22,1053-1063.

### SEASONAL CHANGES IN ANTHROPOMETRY, PERFORMANCE, HORMONAL STATUS AND MUSCLE DAMAGE OF ELITE AUSTRALIAN RULES FOOTBALL PLAYERS

BILSBOROUGH, J.C., GREENWAY, K., OPAR, D., CORDY, J., COUTTS, A.J.

UNIVERSITY OF TECHNOLOGY SYDNEY/CARLTON FOOTBALL CLUB

SEASONAL CHANGES IN ANTHROPOMETRY, PERFORMANCE, HORMONAL STATUS AND MUSCLE DAMAGE OF ELITE AUSTRALIAN RULES FOOTBALL PLAYERS Bilsborough, J.C. 1,2), Greenway, K. 3) Opar, D. 3) Cordy, J.2) Coutts, A.J. 1,2) 1) Elite Performance Unit, Carlton Football Club, Australia, 2) University of Technology Sydney (UTS), Australia, 3) Royal Melbourne Institute of Technology, Bundoora, Australia. Keywords: Introduction Australian Football (AF) players typically complete two distinct phases of training during the season, the preseason (PS) and the inseason (IS). The PS phase typically consists of higher load training where physiological and technical/tactical skills are developed. During the IS, training loads are lower as the focus of training is to recover players for the regular weekly competitions. At present, the seasonal changes in anthropometry, hormonal status and performance are not well known. Therefore the purpose of this study was to examine the seasonal changes in these parameters in professional AF players. Methods Forty seven professional AF players were assessed for anthropometry (body mass (BM), lean mass (LM) and body fat (BF)) with a pencil beam DEXA (Lunar DPX-IQ, GE) five times during the 2010 season (start-PS, mid-PS, start-IS, mid-IS, end-IS). Salivary testosterone (S-Test), cortisol (S-Cort), blood creatine kinase (CK) and physical performance characteristics (bench press, bench pull, BM jump squat) were also taken at these times. A one-way ANOVA was used to detect differences between tests. Pearson's correlations were determined. Significance was set at  $P < 0.05$ . Results BF decreased during the PS ( $P < 0.01$ ) but was maintained through the IS. Since BM was unchanged during the season, %LM was increased during the PS ( $P < 0.01$ ) and remained constant thereafter. Compared to the start-PS, the S-Test was lower at mid-PS until the end of IS ( $P < 0.01$ ). S-Cort was reduced from the beginning of PS to the end-IS ( $P < 0.01$ ). T-C remained constant throughout the PS but was reduced at mid-IS ( $P < 0.01$ ). CK was higher at the end of PS and declined during the IS ( $P < 0.01$ ). Upper body strength increased during the PS and was maintained during the IS. Peak distance and peak velocity from BM squat jumps increased during the PS and decreased during the IS ( $P < 0.001$ ). Changes in LM were related to changes in upper body strength performance ( $r = 0.23-0.35$ ,  $P < 0.05$ ). Discussion These findings show that the training program for this team was effective for maintaining LM and strength/power characteristics during the PS. However the reductions in jump performance during the preseason may be due to the lower training dose or accumulated fatigue during the season. Although the hormonal and muscle damage markers changed during the season they were not related to changes in physical performance. Future studies should examine factors influencing these seasonal changes and to assist scientists manage training during the AF season.

### SEASONAL BIRTH EFFECT AND PHYSICAL FITNESS OF SUCCESSFUL YOUNG SOCCER PLAYERS

FERREIRA, J.I, FRAGOSO, I.I, MASSUÇA, L.I,2

1: FMH-UTL (LISBON, PORTUGAL); 2: ICPOL-ISCPSI / FEFD-ULHT (LISBON, PORTUGAL)

Introduction It is commonly accepted the idea that physical fitness, particularly speed, resistance and strength has a great influence in sports performance. The purpose of this study was to show how seasonal birth effect influence physical fitness variables and the performance level of young elite soccer players, disregarding the effect of bone age. Methods A total of 133 under-15 young soccer players were studied. Aerobic capacity, speed, reactive strength and soccer-specific evaluations were measured. The aerobic capacity was evaluated through the Yo-Yo Intermittent Test (Bangsbo, 2002). The speed was evaluated through the Linear 30-m Speed Test (time in 10-m and 30-m). The reactive strength was measured through the Squat Jump and the Countermovement Jump. Soccer-specific performance was obtained according to the success level achieved by each soccer player: Level 1, representing those who were dismissed from the club (27.8%); Level 2, a player that stayed on the club but was never called to a youth selection (28.6%); Level 3, a player that is called to the district selection (23.3%) and; Level 4, a player of youth international level (20.3%). Maturity (bone age) was evaluated through Tanner-Whitehouse III Method (TW III). The 4 groups were compared with ANCOVA using the SPSS for windows (v.18.0). Permissions from parents and from the boys (self assent) were obtained before data collection. Results The athletes that achieve a higher degree of success in soccer are the ones that obtain better scores in the speed (1-2;1-3;1-4) and in resistance (1-4) tests (all,  $p < .05$ ) and it should also be noted that most of the athletes are born during the first semester of the year (77.4%). The results showed some differences between the studied groups (trimesters) even after removing the bone age effect. The athletes born in the first and second trimester are significantly faster than the athletes born in the others (1-3;1-4;2-3;2-4). In addition, the athletes born in the first trimester performed worse in Squat Jump test, although the results were only significant between the first and second trimester (1-2) as result of the number of subjects included in other groups. Discussion Soccer coaches reveal a tendency to choose athletes with superior aerobic capacity and faster, which demonstrates that they do not choose athletes only because of their technical skills. They make a more global analysis where they include fitness, in particular speed, as part of their perception of success in the game. The results above show the relevance of the seasonal birth effect in physical fitness tests particularly in speed even after removing the bone age effect. References Bangsbo J (2002). Entrenamiento de la condición física en el fútbol. Barcelona: Editorial Paidotribo.

## OPINION FROM ELITE YOUNG SOCCER ON CARDIOVASCULAR HEALTH ISSUE

MEMA, F.1, KURIU, A.1, MARTIRI, A.1, QELESHI, A.1

UNIVERSITY OF SPORTS, TIRANE

Opinion from elite young soccer on Cardiovascular Health issue Mema,F .1, Kuriu ,A.1,Martiri,A.1,Qeleshi, A.1, 1: UNIVERSITY OF SPORT OF TIRANA Introduction: Participation in physical activity during childhood may have an indirect effect on risk-factors for cardiovascular disease, by helping children to prevent excess weight gain or helping overweight children to lose weight (Department of Health, 2004). Although chronic diseases are infrequent in youth, risk factors are present and track from childhood to adult life. (Goran, M.I., et. al 1999, Rolland-Cachera, M.F., et. al 1999) .This modest study try to see what's the opinions of young profesionist soccer on this debate topic .They are so young and training so hard but are they aware about Cardiovascular Health etc? Objectives: To objectively see and investigate the cardiovascular problem and they opinion among young soccer from best Albanian team U 17 and U19. Subjects: This study engages 125 young between 17 and 19 years old that participate in five football teams: S.K.Trana, Patizani, Dinamo, Shkendia including in national championship football under 17 and 19 years old. Methodology: questionnaire assessment cardiovascular has been applied. (Poul M.Insel and Walton T .Roth 1988). Results: Data from questionnaire according to scale show: In U 17 at moderate level 19.5 %, superior level 27.5 %, optimal level 53 % In U19 at moderate level 36 %, superior level 28%, optimal level 36 % Discussion: This study show a interesting data analyzed and compared with transformation socio-economic status that our country is going throw, changing mentality hand by hand with our way of thinking. The young soccer 17 years old for five team seem to have better data than U 19 and in general for both ages values are optimistic and significant showing that actually we have a awareness and understanding in the most of them about Cardiovascular Health issue. ### PP-PM29 Children and Ageing

#### A MATHEMATICAL MODEL OF THE RELATIVE AGE EFFECT

WERNINGER, L.

TECHNICAL UNIVERSITY MUNICH

A MATHEMATICAL MODEL OF THE RELATIVE AGE EFFECT (RAE) Werninger, L., Lames, M. TUM (Munich, Germany) Introduction There is some debate on the methodological treatment of the RAE. To test its significance a Chi-Square test or the Kolmogorov-Smirnov test are frequently used. Moreover, Augste and Lames (2011) suggest characterizing the strength of a RAE by the median of the birth days in the corresponding sample. This paper suggests a mathematical model for a RAE and provides two indices that characterize the underlying selection process leading to the respective RAE. STA (Selection Threshold Applied) is an estimate for the percentage of the population eligible to the sample, and MLA (Maturity Level Applied) is the corresponding biological age expressed in years ahead of the maturation level of the population. Method The probability of being selected is assumed to be proportional to having a certain maturity level or biological age at time of selection. Biological age may be assumed to be normally distributed with chronological age as mean value and a standard deviation spop that is typical for the population the sample is drawn from (Sherar et al., 2007). From these assumptions one may calculate the probability of having a certain biological age x. The probability of being selected is considered to be proportional to this biological age. As the sample is composed of athletes born at the kth of n time intervals the probability distribution selection probabilities can be calculated dependent on x. MLA is the x-value that gives the best approximation of the sample's empirical distribution. STA is the probability of having MLA as biological age. Results The model was applied to four different samples in youth football of different selection level and sample size. RMSE as goodness-of-fit indicator varied from 0.49% in the largest (national training camps, n=22,238) to 3.25% in the smallest (U17 first league team, n=26) sample. Correlations between observed and expected values ranged from 0.917 to 0.986. Processes employed to select German national youth team players are characterized by a MLA of 2.58 years ahead of population that corresponds to 0.5% of the population being eligible. Discussion Modeling the RAE based only on the assumption that a biological threshold is applied has turned out to be successful in terms of conceptual considerations and the goodness of fit results in different samples. Although problems of prediction grow with decreasing sample size even results for small samples give a valid description of the underlying selection process. References Augste, C., Lames, M. (2011). *J Sports Sci*, (subm.). Sherar, L. B., Baxter-Jones, A. D., Faulkner, R. A., Russell, K. W. (2007). *J Sports Sci*, 25(8), 879-886.

#### SCALING OF AEROBIC FITNESS IN 9-11 YEAR OLD LIVERPOOL CHILDREN

GRAVES, L.E.F.1, STRATTON, G.1, BATTERHAM, A.M.2

1 LIVERPOOL JOHN MOORES UNIVERSITY, 2 TEESIDE UNIVERSITY

Objective: How aerobic fitness (VO2 peak) data is scaled to partition out the influence of body size is important to our understanding of current and secular trends in youth fitness. The ideal method is to scale VO2 peak to a direct quantification of the metabolically active muscle mass during the fitness test (Tolfrey et al., 2006). The aim of this study was to investigate the appropriateness of using lean mass of both legs as a scaling variable for VO2 peak compared to total lean body mass and total body mass. Methods: 126 girls (age mean 10.2, SD 0.9) and 87 boys (age mean 10.4, SD 0.9) provided acceptable VO2 peak scores from an incremental treadmill protocol to volitional exhaustion. Dual-energy x-ray absorptiometry measured total lean mass of the body and the sum of both legs. We used allometric regression models of the form  $\log \text{VO2 peak} = \log a + b (\log \text{body size})$ , adjusted for biological sex and maturity offset (years from peak height velocity; PHV). Three models were compared, each using a different index of body size; total body mass, total lean body mass, lean mass of both legs. We assessed goodness of fit using the Akaike Information Criterion (AIC) with Akaike weights for each model computed from the derived AIC values. Results: The Akaike weight for the model using the lean mass of both legs as the index of body size was 0.91; this is the probability that this model is the best from the set of candidate models. The Akaike weight for the next best model (total lean body mass) was 0.09. The size exponent (b) for lean leg mass was 0.59 (95% CI, 0.48 to 0.71). Both sex and maturity offset contributed substantially to the model. After controlling for body size and maturity offset the VO2 peak in boys was 19% higher than

in girls [95% CI, 13 to 26%]. After controlling for body size and sex a 1-year increase in maturity offset (closer to PHV) was associated with a 5% higher VO<sub>2</sub> peak [95% CI, 2 to 8%]. Conclusion: The model using the lean mass of both legs was more than ten times as likely to be the best model as that using total lean body mass. The model using total body mass as the indicator of body size was very unlikely. Compared to surrogate markers of metabolically active muscle mass during a fitness test, such as total body mass, lean mass of both legs appears a more appropriate scaling variable for VO<sub>2</sub> peak in children. #### **A STUDY OF STRESS RELATED TO URINARY INCONTINENCE IN HIGH SCHOOL AND UNIVERSITY-AGE FEMALE ATHLETES IN JAPAN**

SAHO, Y., SHIGEHIO, T.

*INSTITUTE FOR HEALTH AND EXERCISE SCIENCE*

**A STUDY OF STRESS RELATED TO URINARY INCONTINENCE IN HIGH SCHOOL AND UNIVERSITY-AGE FEMALE ATHLETES IN JAPAN** YAMAMOTO Saho, TANAKA Shigehiro Introduction The occurrence of urinary incontinence is not so rare in female athletes, however there have not been clear reports of the urinary incontinence in female athletes in Japan. Therefore, we investigated the prevalence of urinary incontinence and urge incontinence in younger female athletes in Japan. Methods We studied the prevalence of urinary incontinence in high school and university-age female athletes in Japan aged 15-22 (n=245) by questionnaire (response rate 100%). Statistical analyses of the results included the test and chi-square test. Results of  $P < .05$  was considered significant. Results The prevalence of stress urinary incontinence (SUI) and urge incontinence was reported by 53 of the 245 participants. The athletes who experiencing SUI and urge incontinence were heavier and older than non-SUI athletes. Activities which were most likely to provoke SUI included jumping (37%), running (37%), high-impact activities (16%). The age the participants reported first noticing SUI and urge incontinence was during a sports related activity: 24% (elementary school), 22% (junior high school) and 7% (high school). The time of SUI people spent exercising was significantly longer than that of non-SUI people. There were no significant findings between the effort to prevent SUI and the outcome of SUI prevention. Discussion As for weight, one of the risk factor of SUI is being overweight. Intra-abdominal pressure and pressure in the bladder rise with weight gain, then these factors may the chance of increase SUI (Yasuhiro. S et al., 2005). Concerning age, the cause may possibly be the insufficient of estrogen. However, as this study is intended to analyze high school and university-age participants, it is unlikely that estrogen is the root of SUI. University-age participants have more opportunity to exercise than high-school age participants. This difference is thought to be a significant factor between SUI and non-SUI. The previous studies, in which non-Japanese elite athletes were surveyed about when they first noted incontinence, reported 40% in high school and 17% in junior high school (Nygaard I. E et al., 1994). This leads us to the fact that the younger female athletes are, the more likely the risk of SUI they have. Studies concluded that not all of female athletes with SUI were willing to treat SUI. References Yasuhiro, S., Midori, M., Hiromitsu, M. (2005). Risk Factors of Stress Urinary Incontinence. Sanfujinka Chiryo, 91, 392-393. Nygaard I. E., Thompson F. L., Svengalis S. L., Albright J. P. (1994). Urinary incontinence in elite nulliparous athletes. Obstetrics and Gynecology, 84(2), 183-187.

#### **CAN A 6 WEEK SCHOOL BASED ACTIVE PLAY INTERVENTION INCREASE MODERATE-TO-VIGOROUS PHYSICAL ACTIVITY AND DECREASE SEDENTARY BEHAVIOUR?**

O'DWYER, M.V.1, KNOWLES, Z.1, FAIRCLOUGH, S.J.1, RIDGERS, N.D.2, FOWEATHER, L.1, STRATTON, G.1

*1 THE REACH GROUP, LIVERPOOL JOHN MOORES UNIVERSITY, UK 2 CENTRE FOR PHYSICAL ACTIVITY AND NUTRITION RESEARCH, DEAKIN UNIVERSITY, AUSTRALIA*

**Introduction** There is concern that preschool children are not physically active enough to benefit health, yet few interventions have attempted to increase physical activity (PA) in this population. This study aimed to investigate the effectiveness of a 6-week school based Active Play intervention on children's moderate-to-vigorous physical activity (MVPA) levels and sedentary behaviour. **Methods** Participants (n=240; 52% male, Mage = 4.4 ± 0.6 years) were recruited from 12 schools in one large city in England and were randomly assigned to an intervention or comparison group. Intervention schools received one Active Play session (~30 min) per week for 6-weeks from a trained Active Play deliverer. Comparison schools received the Active Play resource pack, which was delivered by the class teacher during curriculum time. PA was measured by uniaxial accelerometer (GT1M Actigraph) for 7 consecutive days using a 5 second epoch before and after the intervention. Data were analysed using age specific cut points (Sirard et al. 2005). For inclusion in the analyses, participants were required to have worn the monitors on 3 days (including one weekday day). A mixed between-within subject's analysis of variance assessed the effectiveness of the two different groups on children's MVPA and sedentary behaviour. **Results** At baseline, preschoolers spent 6.9% (average: 42.3 minutes) of the day in MVPA while 81.5% (average: 642.5 minutes) was time spent sedentary. There was no significant interaction between intervention type and time for weekday MVPA ( $p=0.7$ ) and sedentary behaviour ( $p=0.8$ ). Weekend sedentary behaviour decreased in both groups (average decrease: 31.2 minutes) although this decrease was not significant ( $p=0.6$ ). **Discussion** Low levels of PA at baseline emphasises the need for interventions to increase PA engagement among this population. However, the Active Play intervention did not significantly increase MVPA or decrease sedentary time, possibly because there may not have been an adequate dose of activity. In addition, Bronfenbrenner's Ecological Model (Bronfenbrenner 1989) proposes that for a preschooler the two main influencing factors are parents and teachers; the absence of involving parents may have contributed to the lack of behaviour change. Future interventions focusing on preschool children should aim to include the home environment and run over a longer period of time. **References** Sirard, J.R. et al. (2005) Calibration and evaluation of an objective measure of physical activity in preschool children. Journal of Physical Activity and Health, 3, 357-435. Bronfenbrenner, U. (1989) Ecological systems theory. Annals of Child Development, 6, 187-249.

#### **THE EFFECTS OF A 12 MONTH GROUP-RANDOMISED TRIAL ON FUNDAMENTAL MOVEMENT SKILLS, PHYSICAL ACTIVITY, AND PERCENT BODY FAT IN PRIMARY SCHOOL CHILDREN: THE A-CLASS PROJECT.**

FOWEATHER, L., MCWHANNELL, N., RIDGERS, N.D., GRAVES, L.E.F., HENAGHAN, J., HEPPLER, J., STRATTON, G.

*LIVERPOOL JOHN MOORES UNIVERSITY*

The effects of a 12 month group-randomised trial on fundamental movement skills, physical activity, and percent body fat in primary school children: The A-CLASS Project. Fowweather, L.1, McWhannell, N.2, Ridgers, N.D.3, Graves, L.E.F.1, Henaghan, J.1, Hepples, J.1, & Stratton, G.1 1. Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, UK, 2. Department of Sport and Exercise Sciences, University of Chester, UK, 3. School of Exercise and Nutrition Sciences, Deakin University, Australia. **Background:** Physical activity interventions conducted in UK children are sparse. This study evaluated the effectiveness of a 12 month intervention to increase physical

activity, prevent excess body fat gain, and improve fundamental movement skills among 9-10 year old children. Methods: 152 children (58% response; 41% male), average age 9 years 8 months, were recruited from 8 primary schools in areas of high deprivation. Children were randomised by school to one of four conditions: a bi-weekly high-intensity physical activity after-school club (HIPA; n=36); a bi-weekly multi-skill (fundamental movement skill) after-school club (FMS; n=37); a behaviour-modification programme (PASS; n=45); or a control-comparison (CON; n=34). Outcome measures were assessed at baseline, 9 months and 12 months (post-test) and included 8 fundamental movement skills, measured using video-analysis and process-orientated measures; percent total body fat, determined by means of dual-energy x-ray absorptiometry; and moderate-to-vigorous physical activity (MVPA), assessed by accelerometers over 7 days. Intervention effects were calculated using ANCOVA techniques, with baseline scores as the covariate. Findings were checked for both practical relevance and statistical significance. Results: Fundamental movement skills: At post-test, compared with controls, children in the FMS group significantly improved competence in locomotor (adjusted mean difference (AMD) = 2.52; 90% CI: 1.65 to 3.38,  $P < 0.01$ ) and object-control skills (AMD=3.14; 2.08 to 4.19,  $P < 0.01$ ), whilst HIPA also enhanced competence in locomotor skills (AMD=1.28; 0.35 to 2.19,  $P = 0.024$ ). Body fat: After adjusting for changes in maturation, no intervention effects on percent total body fat were observed compared to controls. Physical activity: No group differences were found for MVPA, which increased from baseline to mid-test but fell sharply at post test in all conditions. Discussion: Multi-skill after-school clubs can improve fundamental movement skills, though skill competence gains were not associated with increased participation in physical activity or lower percent body fat. A subsequent follow up study is warranted to assess long term impact. After-school clubs and behaviour-modification programmes may need to be combined, or supplemented by other intervention strategies (e.g. nutrition), to facilitate positive changes in body composition and increased participation in habitual physical activity.

### A CLUSTER-ANALYTIC CLASSIFICATION OF CHILDREN'S PHYSICAL ACTIVITY: THE CHANGE! PROJECT

MACKINTOSH, K.A.1,2, RIDGERS, N.D.4, BODDY, L.M.1,2, HACKETT, A.F.1,2, DAVIES, I.G.1,2, WARBURTON, G.L.1,2, GOBBI, R.1,2, STRATTON, G.1,3, FAIRCLOUGH, S.J.1,2

LIVERPOOL JOHN MOORES UNIVERSITY

Introduction: Physical activity is a major public health concern as trends show inadequate levels of physical activity for health and rising levels of obesity. A research priority is understanding key explanatory variables underpinning children's physical activity participation. Despite this, there are few studies identifying "clusters" of children based on their physical activity classification levels. This study used cluster analysis in identifying physical activity patterns of children, examining whether different physical activity clusters differ on key explanatory variables. Methods: Two hundred and eighty-nine children (54.7% girls) aged 10-11 years old from 12 primary schools in North-West England completed the Children's Physical Self-Perception Profile, items of Enjoyment, items of Self-Efficacy, and wore a physical activity monitor (GT1M ActiGraph) for seven consecutive days. Sample-specific cut points were generated using a ROC analysis approach in a sub-study based on the recommendations of Welk (2005). Anthropometric measures were completed to estimate maturity status. Cluster analysis was performed to identify homogeneous groups of children based on similar time spent in sedentary, light physical activity (LPA), moderate physical activity (MPA), moderate-to-vigorous physical activity (MVPA) and vigorous physical activity (VPA). Multivariate analyses of variance were then performed to examine differences between clusters on psychological variables and gender. Results: Cluster analysis yielded a four-cluster solution, reflecting low activity, average activity, moderate activity and vigorous activity groupings. There were significant differences in physical activity classifications between all clusters ( $p < .001$ ). There were significant gender differences between the clusters, with the more active clusters consisting of more boys. In addition, clusters of higher activity were associated with higher ratings of self-perception. When controlling for maturity, physical activity differences remained yet all other significant differences between clusters were removed. Discussion: Children who spend more time in MPA and VPA have higher self-perceptions for sport competence, physical condition, body attractiveness, perceived strength, physical self-worth and global self-esteem, but not for enjoyment or self-esteem. Notably, these results also indicate maturity status may differentially influence boys' and girls' physical self-perceptions. References Welk, G.J. (2005). *Med Sci Sports Exerc*, 37, S501-S511.

### REVISITING SOME METHODOLOGICAL APPROACHES OF THE USE OF GPS IN MEASURING THE FREE-LIVING PHYSICAL ACTIVITY OF YOUNG PEOPLE

COLLINS, P., AL-NAKEEB, Y., NEVILL, A., LYONS, M.

NEWMAN UNIVERSITY COLLEGE

Previous literature has recommended specific guidelines with regard to how many days of testing are necessary to provide an accurate reflection of an individual's 'average day' when measuring free-living physical activity (PA) levels (Tudor-Locke et al., 2005). However, whilst technological advancements have led to methodological development in measuring young people's PA levels, this has not transcended into updating the traditional guidelines. Trost et al (2000) has been widely supported in stating that when objectively measuring PA levels, a minimum of four days including weekend and weekdays are necessary. The recent technological development in the global positioning system (GPS) has led researchers to combine the use of GPS with more traditional tools to objectively measure PA levels. However, whilst guidelines regarding the number of days necessary for PA measurement with traditional objective tools such as pedometers and accelerometers are continually supported, no research has specifically addressed this issue with regard to the use of GPS. This has led to the majority of studies adopting a four day testing policy when utilising GPS to measure PA. Recent reviews have highlighted the potential in utilising GPS effectively as a measure of PA (Maddison and Mhurchu, 2009). Hence, the current study attempts to investigate whether the traditional method of 4 days testing is the most appropriate for measuring PA with GPS. This study explores the possibility of measuring young people's free-living PA over a whole week (instead of a four day period) to ascertain whether this helps eliminate some of the drawbacks of utilising GPS. The study reviews recent research literature and investigates different methodological procedures for measuring PA using GPS combined with heart-rate monitoring. A total of 50 adolescents (22 M, 28 F) wore GPS and heart rate devices over a period of 7 days. 16 participants wore the devices for 7 consecutive days, with 34 participants wearing the devices consecutively for four days (Monday to Thursday) before having a short break (several days) after which the devices were worn over a weekend period (Friday to Sunday). Statistical procedures were performed to reveal significant differences between various methods of measuring PA. This entailed testing for participant reactivity, variance in daily moderate-to-vigorous PA, and analysing the pattern of participant compliance over the 7 day testing period. Gender and school type differences were also analysed. The results of the study draw several insightful conclusions which should be considered by future researchers measuring PA with GPS.

## ENERGY EXPENDITURE MEASUREMENTS UNDER CONTROLLED CONDITIONS AND IN THE FIELD - COMPARISON OF OVERWEIGHT AND NORMAL WEIGHT WOMEN USING INDIRECT CALORIMETRY AND ACTIVITY MONITORS

GRAMS, L.1, TEGTBUR, U.1, MARSCHOLLEK, M.2, KUECK, M.1, KERLING, A.1

MEDICAL SCHOOL HANNOVER

Introduction Physical Activity (PA) is an important factor to remain physical and mental health. Activity monitors are widely used to detect physical activity (PA) and quantify energy expenditure (EE) (Garatachea, 2010). For developing strategies against the worldwide increase of physical inactivity and its related health problems, accurate EE measurements are essential. Therefore physical activities of daily living (PADL) have been measured in normal weight (NW) and overweight (OW) women using accelerometer and indirect calorimetry. Methods 35 women (age=41±13) were divided in two groups (NW: n=19, BMI=21±2; OW: n=16, BMI=29±3) and completed PADL (15min of Resting Metabolic Rate (RMR), computer work, vacuuming, stair stepping, cycling and 6min walking), wearing the multisensor device SenseWear Armband (SW), a triaxial accelerometer (RT3) and the portable ergospirometry system Oxycon Mobile (OM). Additionally participants wore SW at home (SWH). Results EE measurements of SW and RT3 are significant ( $p<0.01$ ) compared to OM for both groups for walking, stair stepping and cycling. SW is not significant in RMR and vacuuming compared to OM, whereas RT3 shows significant results for vacuuming in both groups. EE differences of both sensors compared to OM increase with higher levels of PA. Comparing OW vs. NW, OW showed higher EE in RMR (7%), walking (12%) and stair stepping (20%). Analysis of SWH over 24 hrs showed less PA ( $p<0.01$ ) in OW (501 kcal/d) compared to NW (active EE 897 kcal/d). Discussion Activity monitors are helpful to detect the quantity of physical activity. SW, as multi-sensor device, measures more accurate than RT3, which shows a lack of accuracy in activities with less vertical or horizontal acceleration (Jacobi, 2007). Overweight women showed greater EE in activities with moderate intensity than normal weights (LeCheminant 2010). When referring EE results to nutrition analysis, using accelerometer in health care programs to reduce body weight and increase PA requires careful interpretation due to possible under- or overestimated EE by accelerometer. References LeCheminant J et al. (2009). *Eur J Appl Physiol*, 106, 675-682. Garatachea N et al. (2010). *Nutr. Hosp*, 25 (2), 224-230. Jacobi D et al. (2007). *Obesity*, 15 (4), 950-956.

## THE EFFECT OF STRUCTURED AND LIFESTYLE PHYSICAL ACTIVITY INTERVENTIONS ON BODY FAT IN 9-11 YEAR OLD CHILDREN.

MCWHANNELL, N.

UNIVERSITY OF CHESTER

The effect of structured and lifestyle physical activity interventions on body fat in 9-11 year old children. McWhannell, N.1,2, Henaghan, J.2, Fowweather, L.2,3, Reilly, T.3, Stratton, G.2,3. 1: UC (Chester, England), 2: REACH (Liverpool, England), 3: LJMU (Liverpool, England). Introduction Increasing the physical activity (PA) levels of children is a key objective in health promotion strategies. Physical activity intervention studies attempting to reduce body fat have had limited success and have been less than robust methodologically. This study implemented different structured exercise interventions alongside a lifestyle intervention and compared changes in body fat and habitual PA over a 12 month period. Methods 144 children (girl n=86, boy n=58), from 8 randomly selected schools participated in the 12 month study, 2 schools were randomly allocated into 1 of 4 groups: high-intensity (HIPA), skill development (FMS), lifestyle (PASS) and control (CONT) groups. The HIPA and FMS groups participated in an after-school club (2x60 min.week-1), the PASS group attended a weekly classroom session (40 min) delivered by a lifestyle coach. The CONT group received health information. Dual-energy x-ray absorptiometry (DXA) was used to measure body fat mass (kg) and percent body fat (%) and habitual PA levels were quantified using accelerometer at baseline and 12 months. ANCOVA, with baseline scores and maturity offset values as the covariates, was used to evaluate the effect of the intervention on body fat. ANCOVA, with baseline habitual PA as a covariate was used to evaluate the effect of the intervention on PA. Results The CONT group displayed the greatest increase in fat mass, percent body fat and percent trunk fat over the 12 month intervention. All intervention groups changes in fat mass were significantly less than changes observed by CONT group (all  $P<0.05$ ), with the HIPA group showing the least change ( $P=0.03$ ). No significant changes were found in % body fat. The FMS group displayed the least change in % trunk fat ( $P=0.03$ ). Neither group displayed a significant change in time spent in PA compared to CONT group. Discussion All treatment groups showed significantly smaller increases in fat mass compared to CONT group. On the basis that the HIPA group gained fat at a slower rate than other groups, the HIPA intervention had most effect on minimising the fat mass accumulation. This finding supports the consensus that time spent in vigorous PA is associated with lower levels of body fat (Gutin et al., 2008; Ruiz et al., 2006). Neither intervention increased PA levels. A 60 min programme of structured PA (HIPA and FMS) performed twice weekly stimulated a significant effect on minimising the accumulation of body fat in 9-11 year old children. References Gutin, B., Yin, Z., Johnson, M. and Barbeau, P. (2008). *Int J Pediatr Obes*, 3, 3-9 Ruiz, J.R., Rizzo, N.S., Hurtig-Wennlof, A., Ortega, F.B., Warnberg, J. and Sjostrom, M. (2006). *Am J Clin Nutr*, 84, 299-303.

## ARE RURAL CHILDREN REALLY HEALTHIER? CASE OF CROATIA.

NOVAK, D., PODNAR, H., NELJAK, B.

FACULTY OF KINESIOLOGY, UNIVERSITY OF ZAGREB, CROATIA

Are rural children really healthier? Case of Croatia. Novak Dario (Faculty of Kinesiology, University of Zagreb), Podnar Hrvoje (Faculty of Kinesiology, University of Zagreb) INTRODUCTION This study aims to determine health status of 5th to 8th grade pupils through registering health-related indicators and compares physical fitness level of students from urban areas and their peers from rural domain. METHODS Subjects were school children enrolled in grades 5th to 8th. Sample consisted of 9685 students, 4924 girls and 4761 boys from urban and rural areas of Croatia. A battery of fifteen tests was applied for the evaluation of motor abilities. Coordination, agility, flexibility, explosive and dynamic strength were estimated each with three tests. The differences between the children's physical fitness profiles from urban and rural areas were determined using Anova. A series of t-tests for independent samples were made to compare additionally the subjects. Statistical significance was set to  $p < 0.05$ . RESULTS The results suggest that there are differences in children's health-related physical fitness profiles depending on the rural-urban characteristics. Namely, urban male students had better results in tests for the assessment of agility, flexibility, explosive and repetitive strength than the rural male students, while the urban female students are more successful in tests of agility, flexibility and explosive strength than their peers from rural areas who performed better in flexibility and repetitive strength tests. DISCUSSION AND CONCLUSION Although former researches have shown that students from urban environment hold lower level of kinanthropology characteristics (Pena et al., 2003; Tsimeas et al., 2005; Ozdirenc et al., 2005; Felton et al., 2002) it is to assume that induction of mechanization and lower need for physical work on farms, while maintaining the nutritional habits that involve traditional, high calorie meals, also because of richer offer of organized sport events and programmes in the cities, they change men-

tioned state in benefit of students from urban environment. REFERENCES Ruel M, Garrett J, Morris S, Maxwell D, Oshaug O, Engle P, Me-non P, Slack A, Haddad L. ### ETHNIC DIFFERENCES IN PARENTAL ATTITUDES AND BELIEFS ABOUT CHILDHOOD OBESITY

TRIGWELL, J., WATSON, P.M., MURPHY, R.C., STRATTON, G., CABLE, N.T.

LIVERPOOL JOHN MOORES UNIVERSITY

Introduction Childhood obesity in the UK is a serious public health concern, particularly in ethnic groups where prevalence is higher (Department of Health, 2010). It is important to understand ethnic differences in parental attitudes to childhood obesity so that interventions can be tailored appropriately to the needs of ethnic groups (NICE, 2006). The aim of this study was to examine how parental attitudes and beliefs about the causes of overweight in childhood varied with ethnic background. Methodology A self-report questionnaire was designed to explore parental attitudes surrounding childhood weight and beliefs about the causes of overweight in childhood. Eight hundred and eight parents of children aged 4 to 16 years who self-identified their ethnic background as White British (n=603, 75%), Black Somali (n=43, 5%), Chinese (n=41, 5%), Black African (n=40, 5%), South Asian (n=28, 3%), Asian British (n=27, 3%) or Yemeni (n=26, 3%) completed the questionnaire. Differences in parental attitude were analysed using Chi-Squared and significance was set at  $p \leq 0.05$ . Results There were significant ethnic differences in parental attitudes and beliefs about overweight in childhood. Black Somali parents (64%) were more likely than South Asian (19%) and Yemeni (20%) parents to view overweight children as healthy ( $X^2(12, n=780)=25.17, p<0.05$ ). Eighty-six percent of White British, 83% of Chinese and 81% of Asian British parents believed both dietary and physical inactivity factors played a role in the development of overweight in childhood, compared to only 38% of Yemeni parents ( $X^2(6, n=803)=62.95, p<0.001$ ), who attributed overweight in childhood to dietary but not physical activity causes (50%). Conclusion Parental attitudes and beliefs about overweight in childhood were significantly associated with ethnic background. It is important to draw on these differences in the design of and recruitment to childhood obesity interventions aimed at ethnic minority groups. References Department of Health. ### AGING AS A NATURAL PROCESS AND VALUABLE HUMAN RESOURCE

KAPEDANI, K.

UNIVERSITY OF SPORT TIRANA

Aging as a natural process and valuable human resource Kapedani,K.1,Fortuzi,I .1,Qeleshi, A.1, 1: UNIVERSITY OF SPORT OF TIRANA Introduction: This study explore the understanding of aging .Using questionnaires for some groups of the population also need specific questionnaires that are related to their habits and surroundings (Montoye H .J .at al1996 ; Kohl H.W,at al 2000) and in mean time questionnaires, either self-reported or interviewer-based are commonly used ( Sallis J.F.at al 2000; Sirard JR at al 2001). Our study tries to light inside thoughts and memories of young generation (students) about aging facing with trendy and tendency changes that go throw to mentality and transitory society . Objectives: To objectively investigate the understanding problem of aging in our student, the avant-garde of our society. Subjects: This study engages 510 student 19 years old -boys at University of Tirana including 4 Faculty Methodology: Questionnaire assessment for understanding and debating of aging has been applied. (Poul M.Insel and Walton T .Roth 1988). Results: Data from questionnaire , according to scale , show: Faculty of economic - Marginal level 0 %(boys % girls %) , moderate level 43 %(boys 5 % girls 38%), superior level 49 % (boys 6 % girls 43 %), optimal level 8 %(5 boys 3 % girls Faculty of Jurisprudence - Marginal level 14%(boys 2% girls 12%) , moderate level 38%(boys10 % girls28 %), superior level 42 % (boys 10 % girls 32%), optimal level 6%( boys 2 % girls4%) F of History & Philology - Marginal level 12.5 %(boys 2.5% girls 10%) , moderate level 45%(boys 2.5% girls 42.5 %), superior level 35 %(boys10 % girls 25%),optimal level 7.5 %( boys 0% girls 7.5%) F of Foreign Language - Marginal level 7 %(boys 2% girls 5 %) , moderate level 42%(boys0 % girls 42%), superior level 44% (boys 7% girls 37%), optimal level 7%( boys0 % girls 7 %). Discussion: This study demonstrates a significant awareness about aging among students 19 years old of four faculty ,specially Faculty of Economy with data superior level 49 % (boys 6 % girls 43 %), optimal level 8 %(5 boys 3 % girls, where according to scale these levels consider old age as e stage in life ,consider aging as a natural process ,feels older people as a valuable human resources that can make significant contributions . #### EFFECTS OF COMPENSATORY STRENGTH TRAINING PROGRAM ON SHOULDER ROTATOR CUFF BALANCE AND MUSCULAR FATIGUE IN YOUNG SWIMMERS

BATALHA, N.,1 RAIMUNDO, A.1,2, TOMAS-CARUS, P.1,2, PEREIRA, C.1, SILVA, A.J.3,4

1:UNIVERSITY OF ÉVORA, PORTUGAL, 2:HEALTH SCIENCE AND TECHNOLOGY RESEARCH CENTRE, 3:UNIVERSITY OF TRÁS-OS-MONTES AND ALTO DOURO, PORTUGAL, 4:RESEARCH CENTRE OF SPORTS, HEALTH AND HUMAN DEVELOPMENT.

Introduction The purpose of this study was to evaluate de effects of 16 week compensatory strength training program in shoulder rotators balance and muscular fatigue in young swimmers. Methods A total of 40 male swimmers were assessed and randomly divided in two

groups: experimental group (n=20; age: 14.65±0.67 years old, height: 173.48±6.87 cm, body mass: 63.15±5.68 kg) and control group (n=20; age: 14.60±0.60 years old, height: 170.79±6.48 cm, body mass: 61.73±4.68 kg). Experimental subjects participated in a 16 week shoulder strength program with Thera-Band® elastic bands (3 times a week). The external rotator /internal rotators ratio (ER/IR) and fatigue ratio were measured in both groups at baseline and after 16 weeks. Concentric action at 60°/s (3 reps) and 180°/s (20 reps) were measured, in a seated position, with the shoulder at 90° of abduction and elbow flexion, using an isokinetic dynamometer (Biodex System 3). The muscular fatigue protocol consisted in 20 maximal-effort repetitions of ER and IR at 180°/s. Anova with repeated measures was used to determine significant main effects in unilateral ER/IR ratios and fatigue ratios. The level of significance was set at 0.05. Results Considering ER/IR ratio, a compensatory strength training programme induces significant differences in both shoulders at 60°/s (Dominant: P=0.001; Non dominant: P=0.001). At 180°/s we just found significant effects on the Dominant shoulder ER/IR ratio (P=0.002). With respect to fatigue ratios, we found no differences between groups from baseline and 16 weeks. Discussion Our results show that 16 weeks of compensatory strength training improve ER/IR ratio, nevertheless, were not enough to improve fatigue ratios, representing the rotators shoulder muscular resistance. This results support earlier research (Malliou et al., 2004) that showed that the unilateral shoulder strength ratios increases substantially after a period of a strength training program. Since the ratios describe the quality of muscular balance/imbalance (Ellenbecker & Davies, 2004), we can conclude that a 16 week compensatory shoulder strength training program using Thera-Band® elastic bands, reduces muscular imbalances in rotator cuff of competitive young swimmers. These results highlight the useful of this kind of compensatory program to prevent shoulder injuries. References 1. Malliou, P.C. Giannakopoulos, K. Beneka, A.G. Giotsidou, A. and Godolias, G. ### EFFECTS OF LOCALIZED AND GENERAL FATIGUE ON POSTURAL CONTROL IN MALE TEAM HANDBALL ATHLETES

STEIB, S., ZECH, A., HENTSCHE, C., ECKHARDT, H., PFEIFER, K.

UNIVERSITY OF ERLANGEN-NUREMBERG

Introduction: In team sports, muscular fatigue and sensorimotor impairments have been identified as factors contributing to an increased injury risk (Hawkins & Fuller, 1999; Plisky et al., 2006). However, little is known to what extent exercise-induced fatigue influences sensorimotor mechanisms. This study determined the effects of general and localized fatigue on static and dynamic postural control in team handball athletes. Methods: Nineteen healthy male youth handball players (age: 16.8±0.6 years; height: 179.9±6.9 cm; mass: 73.5±10.8 kg, first and second division) performed (1) a treadmill fatigue protocol and (2) fatiguing single-leg step up exercises in two sessions separated by one week. Before and immediately after the fatiguing exercise, center of pressure (COP) sway velocity during a single-leg stance on a force plate and maximum reach distances of the star excursion balance test (SEBT) were used to assess static and dynamic stability during upright standing. A two respectively three factorial linear mixed model, was specified for each of the main outcomes. The experimental factors 'fatigue', 'protocol' and 'eyes condition' were included as fixed factors nested in the individual's factor. Results: COP sway velocity increased significantly ( $p<.05$ ) following general (+47%) and localized fatigue (+10%). No fatigue effects were found for the SEBT. No association was identified between COP sway velocity and SEBT mean reach distance. Discussion: In conclusion, the increase in COP sway velocity following general and localized muscle fatigue suggests, that both fatigue dimensions change neuromuscular/sensorimotor control mechanisms and may influence the injury risk in team handball athletes. Further research is needed to clarify the impact of fatigue on dynamic balance. References: Hawkins RD, Fuller CW (1999). Br J Sports Med 1999, 33(3), 196-203. ### THE FACTORS RELATED TO LOW BACK PAIN IN JAPANESE ELITE JUNIOR DIVERS- ANALYSIS OF PHYSICAL AND TECHNICAL CHARACTERISTICS-

TAKAYA, N., KOJI, K., MASAHIRO, T., SHUMPEI, M., YOSHIRO, S., TAKAMICHI, N.

HEALTH SCIENCE UNIVERSITY

During Competitive diving, divers jump up from 1-3m springboards or 5-10m platforms and dive into the water. The impact forces are very large in the water entry phase, and therefore, microtraumatic injuries are common because of tremendous physical stress placed on a diver. This study aimed, 1) to describe the prevalence of injuries during a 6-year period and 2) to extract possible risk factors related to low back pain (LBP) from physical and technical characteristics, in Japanese elite junior divers. One hundred and seventeen (61 males, 56 females) elite junior divers in Japan were included in this study. LBP that the divers experienced were assessed by questionnaires, interviews, and physical examinations during national training camps. Morphological data, physical fitness, and diving skills were evaluated. The factors related to LBP were extracted with logistic-regression analysis using the forward selection method (likelihood ratio). In total, 114 reports of pain were recorded. 39.4% of pain occurred in the lumbar lesion (forty-nine reports), and most occurred in the water entry phase. Shoulder flexibility and age were recognized as factors related with the LBP in male elite junior divers, while only age was a factor in female elite junior divers. Our results suggested that shoulder flexibility is important to prevent LBP in the elite male junior divers, since divers require full shoulder flexion in the water entry phase. Limited shoulder flexibility could cause lumbar hyper-extension when adjusting the angle of water entry. The major findings of this study were: 1) Among all types of injuries, there was high prevalence of low back pain (39.4%) in elite junior divers in Japan. 2) Most injuries occurred in the water entry phase. 3) Shoulder flexibility and age were related to low back pain among the males. 4) Age was related to low back pain among the females.

### BENEFICIAL EFFECTS OF AEROBIC TRAINING IN ADOLESCENT PATIENTS WITH MODERATE IDIOPATHIC SCOLIOSIS

VILLAR AURA, J., GOMEZ-CABRERA, M.C., ROMAGNOLI, M.

CATHOLIC UNIVERSITY OF VALENCIA

BENEFICIAL EFFECTS OF AEROBIC TRAINING IN ADOLESCENT PATIENTS WITH MODERATE IDIOPATHIC SCOLIOSIS Villar Aura J.1, Gomez-Cabrera MC2, Romagnoli M. 1,3. 1Department of Sports, Catholic University of Valencia, Spain, 2Department of Physiology University of Valencia, School of Medicine, Spain. 3Department of Physical Education and Sports, University of Valencia, Valencia, Spain. INTRODUCTION Several studies have shown the decrease in the capacity to produce aerobic work in young subjects with mild to moderate AIS (when scoliosis exceeds 25°) [1,2]. These abnormalities may lead to an increase in the energy required for walking or performing other physical activities [3]. However the frequency and the relevance of the restricted work capacity is uncertain and a matter of controversy. MATERIALS AND METHODS 6 weeks of aerobic training in AIS girls that suffer from mild scoliotic curvatures (n=6) and healthy controls (n=6) in different biochemical, anthropometric and cardio respiratory parameters. The groups performing a cycling training program

were subjected to a training program of 3 sessions per week during a period of 6 weeks with an approximate duration of 1 hour per session (table 2). The training intensity was increased from 65% to 85% VO<sub>2</sub>max. All the girls trained every day with a Pulsometer 810R Cardio Polar. RESULTS The maximal power output and the power output achieved at the anaerobic threshold, during the maximal exercise test, were significantly increased in both experimental groups. The training program caused significant changes in body composition (i.e. a decrease in body fat %) only in the scoliotic group. Regarding the cardio respiratory measurements, VO<sub>2</sub>max was increased by 17% in AIS group and by 10% in the healthy group. DISCUSSION We measured in our study the degree of the curve according to Cobb and we did not find any significant modification after 6 weeks of training in a cycle ergometer. Our results suggest that physical activity should be encouraged in scoliotic girls with mild curvatures. BIBLIOGRAPHY 1. ## **MEDIUM-TERM EVALUATION THROUGH RASTERSTEREOGRAPHY OF DORSAL AND LUMBAR SPINE OF VARSITY ATHLETES WITH DIFFERENT TYPES OF LOAD**

BONAVOLONTÀ, V., FRANCIOSI, E., GALLOTTA, M.C., EMERENZIANI, G.P., TITO, A., BALDARI, C., GUIDETTI, L.

UNIVERSITY OF ROME FORO ITALICO

**Introduction** There is a lack of information about modifications of the spine due to the practice of different sport disciplines in non-professional population. Therefore, aim of this study was to investigate about the contribution of different sport disciplines on spine modification in a sample of adult varsity athletes across a six-month sport season. **Methods** 44 varsity athletes (24.5 ± 3 years) were divided into two groups according to the typology of the Sport Team they belonged to: 22 athletes formed the symmetric sports group (S) (track and field running, n=14; cycling, n=8 respectively) and the others 22 formed the asymmetric sports (tennis, n=19; fence, n=3 respectively) group (A). Participants' spine was evaluated through Formetric® 3D (Diers, Germany) rasterstereographic analysis at the beginning (BE), in the middle (MID, after 3 months) and at the end (END, after 6 months) of a sport season. The following parameters were measured and recorded in Average 4D modality: trunk length, trunk imbalance, pelvic tilt, pelvic torsion, kiphotic angle, lordotic angle, pelvic inclination, pelvic dimples inclination, rotation correction (pelvis), kiphotic apex, inflection point ITL, lordotic apex, inflection point ILS, cervical fleche, lumbar fleche, pelvic ante-retroversion, right surface rotation, left surface rotation, trunk torsion, right lateral deviation, left lateral deviation. **Results** Results showed that Intervention factor (BE vs END) had a significant main effect on dimples distance (P<0.05) and on pelvic inclination (BE vs END, P=0.05). Left lateral deviation was also affected by the Intervention factor (BE vs END and MID vs END, P<0.01 and P<0.01 respectively). **Discussion** No statistical differences were found for Sport Typology factor for all the parameters, maybe due to the non-professional technical level of the sample; however, previous studies did not find clinically significant differences even in high-level athletes (Sward, 1992). Instead, referring to Intervention effect on dimples distance, it could be hypothesized that a six-month sport season led an increase of the parameter through pelvic mass hypertrophy. Pelvic inclination, which is related to dimples distance, showed statistical difference in line with that parameter. About left lateral deviation, no modulation was found for Sport Typology: for all athletes, Intervention had an increasing effect suggesting that a deviation can occur independently from the sport load. Asymmetric versus symmetric sport load showed neither statistically significant nor clinically significant differences in a non-professional sample of adult athletes. **References** Sward L. (1992). *Sports Medicine*, 13, 357-364.

## **HUMAN BALANCE EVALUATION IN SUBJECTS WITH CERVICAL INJURIES COMPARED TO HEALTHY SUBJECTS: RESULTS OF A PILOT STUDY.**

BIANCO, A., POMARA, F., PETRUCCI, M., MANCUSO, E., BATTAGLIA, G., BELLAFORE, M., PAOLI, A., PALMA, A.

UNIVERSITY OF PALERMO, UNIVERSITY OF PADUA, SCUOLA DELLO SPORT CONI SICILIA

**Introduction** It is very important that forensic medicine properly calculates the biological damage not only through the disturbance indicated by the patient, but more accurately through instrumental diagnosis. Our aim was to verify through posturography the qualitative and quantitative alterations of postural stability in subjects with cervical trauma, compared to the control group. **Methods** We analysed 78 subjects, selecting 42 volunteers and distinguishing a control group of 22 normal men (NM) and a group of 20 men (WM) with a positive anamnesis of whiplash injury for six months. Through a force platform, we recorded the Centre of Pressure (CoP) movements of these groups, both with their eyes open, and closed. The data was used to compare between the two groups, with both open and closed eyes. **Results** During the closed eyes test, those subjects with cervical injuries, displayed a significant increase in anterior-posterior oscillation velocity (p<0.05) compared to the control group, with a significant reduction (p<0.01) of ratio between Shifting Length (SL) of CoP on the polygon support and total envelop area (EA, mm<sup>2</sup>) of CoP movements in the polygon support (SL/EA-ratio, mm<sup>-1</sup>). During the closed eyes test, subjects with cervical injury showed a significant anterior shifting of the mean position of CoP compared to the other group performing the open eyes test. **Discussion** Our results suggest that posturographic tests can be used to assess and confirm human body imbalance in subjects with whiplash injury. Further studies with more subjects from both sexes are necessary to confirm this pilot study. **References** Endo K, Suzuki H, Yamamoto K: Consciously postural sway and cervical vertigo after whiplash injury. *Spine*. 2008, 33(16):E539-42. ## **THE PREVENTION OF BASKETBALL PLAYERS IN VERTEBRAL PAIN <15-16 YEARS>**

MONDONI, M., CASOLO, F., AJANI, A., BOTTINI, L., PARRAVICINI, F.

UNIVERSITÀ CATTOLICA SACRO CUORE

**The prevention of basketball players in vertebral pain (15-16 years)** **Introduction** In many sports there are combinations of linear and angular movements and in particularly in basketball player movements are carried out on vertical planes, horizontal, in space and time. Some investigations on the lumbar pains among basketball players, show that 60% suffer from periodic or recurrent back pain. **Materials and methods** Before the start of the season 2009-2010, 18 basketball players were undergo a sport medical examination to ascertain their competitive state of health. Before the first training session, the players have compiled one questionnaire containing general news and after the posturologist has completed an evaluation form for each posture. After consideration of responses received, we found that

most of the players complained intermittent back discomfort or pain, especially in the lumbar spine. We subjected the players to 5 test (20 m race, standing long jump, jumping 5 times, Ergojump, tapping). After 2 months another postural control and we proposed to the players the 5 initial tests. During this time, the players have been training continuously on rigid floors and on different types of parquet. After 5 months, the players repeated the 5 test, were subjected to another postural examination and completed a final questionnaire. Results From the results: for 6 players the work was very effective, for 7 fairly effective and for 5 extremely useful. The posturologist, after the final postural examination, showed that the work done during the activation phase has produced undoubted benefits and found that some of the pain had disappeared and that many had trouble at the lumbar spine were weakened or even disappeared. Test results have provided encouraging data, as 13 players have performed better in all tests, 4 players were stable in the results, only one player negative results. Compared to the beginning, the 5 players that early work is not too much pain or discomfort, have maintained the same situation and also improved the executive technique, while those who accused pain at the beginning of work, 6 improved, 5 had a good improvement and 7 do not feel any more pain. Conclusions The exercises to try to reduce the pain were carried out at the start of training with the trainer, so that players could start work in the gym with increasing intensity, with no more pain in the spine. The work, done over 5 months, has raised awareness further players to pay more attention to 'what does' the body during training and competition and to behave accordingly. The tests were useful indicators on the initial, intermediate and final motor situation of the players, note that some key individuals with and without the ball, since the beginning has been made technically better. References B. Toso, Back School, Milano, 2005

## CHANGES IN ROMAND COS OF THE CERVICAL SPINE BY RELAXATION, STRETCHING AND NEURAC-TRAINING

BICHLER, S., PACHATZ, W.

CENTRE OF SPORT SCIENCE AND UNIVERSITY SPORTS, UNIVERSITY OF VIENNA

Introduction Selective neuromuscular reeducation is the basic principle underlying specific training aimed to gain muscular stability and flexibility. Referring to PhysioAustria (2009) sport medicine and sport physical therapy offer a variety of training approaches. However, most of these studies are not evidence based. The research study on hand aims to evaluate a typical training with application for soldiers having high and fasten load on the cervical spine. Method The training program consisted of 3 phases, each 4 weeks in length and a daily training of 10min. Phase 1 included progressive muscle relaxation training (Jacobson, 1990), in order to improve the range of motion (ROM) of the head. Phase 2 followed up with stretching techniques (Evjenth, 1991). Phase 3 aimed at the progression in local joint stability and dynamic stability (Kirkesola, 2010). To rate stability in this context the measurement parameter was the centre of stability (COS). It was defined as the difference of head alignment between participants' subjective middle position and the neutral zero position. 3D-ROM and 3D-COS were measured by XSens™ before and after each phase. The normative values for ROM are depicted as the following: axial rotation left-right (ROT): 140°, extension-flexion (EXFL): 120°, lateral flexion left-right (LAFL): 90°. Male soldiers (mean age 22±2.7 years) of the 1.MilFü2 of HUAk at Enns had to undergo medical examinations to ensure their fitness and health. Results Comparing the ratios and Pearson correlations of beginning and end there are no significant mean differences of ROM between TG (n=18, ROT: 1.02±0.09, 1.06±0.09, r=0.47; EXFL: 0.78±0.13, 0.78±0.12 r=0.55; LAFL: 0.4±0.22, 0.4±0.19, r=0.48) and CG (n=15, ROT: 1.04±0.13, 1.08±0.13, r=0.64; EXFL: 0.71±0.11, 0.68±0.17, r=0.5; LAFL: 0.4±0.14, 0.39±0.12, r=0.51). At the beginning there is a high deficit to the norm in EXFL and also in LAFL, but remains to the end. COS shows a similar pattern for the differences between the beginning and end: TG (ROT: 8.77°±4.21°, 3.62°±11.78°, p=0.19; EXFL: -0.17°±5.27°, -6.09°±5.26°, p=0.13; LAFL: -1.99°±2.07°, p=0.3), CG (ROT: 7.09°±7.71°, p=0.11; EXFL: 0.6°±14.58°, p=0.24; LAFL: -1.59°±3.28°, p=0.19). Discussion However, there are no significant differences between TG and CG. At this stage the training program's preventative goal to gain muscular stability and flexibility cannot be effectively illustrated. Furthermore, it needs to be reconsidered, whether the measurement of COS or the parameter itself allows the accurate display of stability. References Evjenth, O. (1991). Auto Stretching. ## INCIDENCE OF SCOLIOSIS AND BACK PAIN IN YOUNG TENNIS PLAYERS: A TRASVERSAL STUDY

MONDONI, M.

UNIVERSITÀ CATTOLICA SACRO CUORE

INCIDENCE OF SCOLIOSIS AND BACK PAIN IN YOUNG TENNIS PLAYERS: A TRASVERSAL STUDY Mondoni M.1, Negrini S.1, Casolo F.1, Ajani A.1, Bottini L., Vantellino E. Department of Motor Science - Università Cattolica del Sacro Cuore di Milano INTRODUCTION AND OBJECTIVES The purpose of this research is to identify whether the incidence of scoliosis and low back pain (LBP) is most common in young tennis players compared to persons who do not practice this sport. MATERIALS AND METHODS The groups tested (mean age 12-16 years) are the group of players, comprising 50 males and 50 females and the control group (100 males and 100 females), consisting of persons who do not practice courts, for a total of 300 subjects. All subjects were given a questionnaire to fill out anonymously, comprised of 68 questions, whose purpose is to gather data on physical activity and back pain. Were also carried out surveys of the spine to assess the incidence of scoliosis through two instruments: the plumb line and scoliometro (ATR). RESULTS Comparing the ATR measurements, shows that for females, the average is 2.8 in the control group and 3.2 in the Bunnell group of players, whereas in males the average is 2.6 in the control group and 2.8 in the group of players. What has been noted is that a greater number of players present for values of 3 and 4, greater incidence than the control group, but the difference is not aimed at statistical significance, because this is the group of players by 56% (females) and 54% (males). By analyzing the most significant application of the questionnaire, when asked if they had never had back pain, there is no substantial difference between the two groups also are mostly those who have never had. In females, the prevalence of low back pain is greater in the control group compared to the group of players, even if not tending to statistical significance. The male tennis players said they had suffered from back pain than the control group, in fact 77% of the control group and 66% of the players responded 'never' to the question. Comparing males and females, both in the control group is that of tennis, there is a statistical significance from the point of view: the episodes of low back pain are greater in females than males. CONCLUSIONS The study shows that the practice of competitive tennis (boys and girls) does not lead to an increased incidence of scoliosis compared with the control group. From our results, it appears that males and females in the group of players, records of slight asymmetries compared to the control group, but without statistical significance from the point of view. The results of the research shows that females belonging to the control group suffer more back pain than women's tennis team, while, in the case, the male tennis players suffer somewhat higher percentage of back pain than the group of control, but the data are not significant from statistical point of view. ## EVALUATION OF THE OUTER AND INNER SHOULDER ROTATOR MUSCLES OF SWIMMING ATHLETES

MEDEIROS, A.I.A.1, MELISCKI, G.A.2, MONTEIRO, L.Z.3, VASCONCELOS, E.E.4, FURUMOTO, M.A.2

UNIVERSITY OF PORTO – FACULTY OF SPORT, PORTUGAL1, DEPARTMENT OF PHYSICAL THERAPY - UNIVERSITY OF RIBEIRÃO PRETO-SP, BRAZIL2, UNIVERSITY OF SÃO PAULO-SP, BRAZIL3, DEPARTMENT OF PHYSICAL THERAPY OF TH

Introduction: Muscle imbalance has been identified as a common occurrence induced by training (1). Repetitive swimming movements may stress the shoulder joint and swimmers frequently develop rotator cuff tendonitis (2). Objective: To assess the force of the inner (IR) and outer shoulder rotators (OR) of elite swimmers. Methods: Fifteen elite swimmers of the swimming team of the University of Ribeirão Preto, SP, Brazil, aged 18 to 27 years were evaluated. The following data were obtained: age, main swimming style, time of practice (years) and anthropometric data: body mass (kg), height (cm), and body mass index (kg/m<sup>2</sup>). An isometric dynamometer was used to determine the force of the shoulder IR and OR. Data were analyzed statistically by the t-test for paired samples and by Pearson correlation (r), which analyzed the ratio of IR and OR strength of the left and right shoulders of the swimmers. Analysis was performed using the SPSS software, version 16.0. Results: The mean age of the 15 athletes was  $20.5 \pm 2.4$  years, mean weight was  $76.6 \pm 4.7$  kg, and mean height was  $183 \pm 4.9$  cm. The main swimming styles were crawl and butterfly and the time of practice was  $9.28 \pm 4.08$  years. Comparison of the IR/OR strength ratio of the right and left shoulder showed a significant difference. Regarding rotator strength, the swimmers presented a lower IR and OR strength of the left shoulder compared to the right shoulder ( $p < 0.05$ ). We observed that the OR ratio was higher than that of the IR ( $p < 0.05$ ). Conclusion: We conclude that swimming causes changes in OR and IR strength, which may become worse as the swimmers become older and require physical training outside the water to improve their performance. We believe that these results can be used for comparison with data to be obtained in future studies, thus helping the technical committee for the prescription of exercises focusing on the prevention of injuries and on sport performance. 1. #### THE CORRELATION BETWEEN ANTHROPOMETRIC CHARACTERISTICS OF IRANIAN BASKETBALL WOMEN CHAMPIONS WITH THEIR PERFORMANCE IN COMPETITIONS

ADELI, B.

I.R.IRAN BASKETBALL FEDERATION

Mostafail Sabz Persian and Thinking House B.Aadeli, F.Haadavi Belgheis Adeli: I.R.IRAN Coach, Farideh Hadavi: Professor Associate of IAU Introduction In Basketball, the Performance level of champions in a particular sport and achieving athletic success are the subjects to which coaches and athletes have special attention. Assessing players' performances (positive / negative) are rated according to particular position standard indices of (FIBA).Hence, anthropometric parameters take on great importance as some major factors in champions' performance level. Those are focused on: Determining body size (BS), assessing body composition (BC), measuring somatotype(ST) (ISAK level I). Therefore, the aim of this study was to find the Correlation between anthropometric characteristics of Iranian Basketball women champions with their Performance in Competitions. Methods Statistical population for this study included Iranian basketball women champions who were the members of teams participating in national Premier league (2005-2006). According to I.R.IRAN reports, this group consisted of 65 women, using simple random sampling, 21 individuals (guard, forward, center). Through using anthropometric kit; variables of the participations composed of reliability coefficient,  $r = 94$ , and concurrent validity coefficient,  $r = 1$ . Descriptive statistical methods and Pearson correlation were used to data analysis. For comparing a group of anthropometric and performance variables, multiple regression method in alpha 0.05 was employed. All data collected by using SPSS version 16 were analyzed. Results The following paragraph indicates clearly some of these results: ST with positive performance ( $P = 0.62$ )  $F(4,16) = 0.68$   $R^2 = 0.14$   $R = 0.38$  ST with positive performance ( $P = 0.62$ )  $F(4,16) = 0.68$   $R^2 = 0.14$   $R = 0.38$  Results showed that there was no significant relationship between women champions' ST with certain position ( $p < 0.05$ ). Discussion Statistical description of present research findings indicates that ST,BS and BC in the positions (G,F,C) are different. Furthermore, the anthropometric characteristics have considerable effects on players' various performance in different positions through the competition. Results obtained from recent study are consistent with Heath Carter (1990) which indicated players' performance in different positions was affected by ST, BS and BC. General Results of this study may show that ST of players with their positive and negative performances in various positions is inconsistent. Moreover, there is a significant relationship between player's BS and BC with positive and negative performance in the various positions. #### RELATIVE AGE EFFECT OF GERMAN BASKETBALL TALENTS – PHYSICAL AND ANTHROPOMETRIC DIFFERENCES BETWEEN FIRST HALF AND SECOND HALF OF THE YEAR BORN PLAYERS

STADTMANN, T., HOLST, T.

RUHR UNIVERSITY

The aim of our project "Basketball-Talents" is to evaluate and optimize the U16 German Basketball Talent Program. To analyze the output of the talent system, a multidimensional performance assessment was developed: physical condition testing, psychological diagnostic, a sociological questionnaire, regular training documentation and a questionnaire for coaches to evaluate tactical and technical skills. The present study is focused on RAE in combination with results of physical condition testing. Our first question was if there is a RAE in German competitive basketball at all and if this phenomenon is reflected in the anthropometric data and the data of physical condition testing. The physical conditioning testing of 1009 male and 613 female players included: body height (bh), body weight (bw), range of arms (ra), 20 m sprint time (20 m), 5 m sprint time (5 m), 20 m agility-run (20 ar), 20 m agility dribbling (20 ad), jump & reach (jr), standing jump (sj), chest pass (cp), mid distance shot precision (sp) and the multistage fitness test (mf). The chi-square test of the birthdates of regional selected players (U12-U16) divided into born in first half (FH) and second half of the year (SH) showed a significant effect ( $p < 0.05$ )

for boys (65% to 35%) and girls (58% to 42%). A MANOVA (factors: age and half year) showed a main effect (half year) for the anthropometric data of male players (bh, bw, ra): body height and the chest pass. For the female players, there was no main effect (half year) or interaction effect for the physical test performance. In tendency, FH showed better results than SH. The first result of our study is that there is a significant RAE in the German talent program. A player is more likely to be nominated for a regional selection team if she/he is FH than SH. The FH-male players are significantly taller than SH, up to 6cm in early years (U12-1 158,0  $\pm$  8,3 vs. U-12-2 151,7  $\pm$  8,0), which might be an important advantage in playing basketball. Female players in U12 are up to 5 cm taller (U12-1 157,6  $\pm$  7,2 vs. U12-2 152,9  $\pm$  6,8). Surprisingly there aren't many significant effects for conditioning testing even if the FH show better results than SH in tendency. One conclusion might be that SH (and maybe retarded) are not getting the same access to the developing system (better and more training, minutes per game, responsibility) than FH. In U16 the differences in anthropometry and conditioning results between FH and SH are adapting. But in the selection of U16 there are still more FH than SH (male: 68,5%/female: 57,6%). FH still have a profit from their advantage of early years. They are probably more experienced and supported (training, playing time, responsibility) than SH.

## EVALUATION OF PEAK POWER PREDICTION EQUATIONS IN ADOLESCENT BASKETBALL PLAYERS

HANKEY, J.1, LYONS, M.2, DUNCAN, M.1

1: COVENTRY UNIVERSITY (UK), 2: NEWMAN UNIVERSITY COLLEGE (UK)

**Introduction** The ability to generate power is key to successful performance in many sports. Vertical jump height has been widely used in the assessment of power within field settings due to the cost and inaccessibility of force platforms outside the laboratory (Canavan and Vescovi, 2004). Prediction equations have been developed to estimate power from jump height but the validity of these equations is questionable, and research examining the soundness of prediction equations in different athletic groups is needed (Duncan, Lyons and Nevill, 2008). This study sought to evaluate peak power prediction equations in adolescent basketball players. **Method** Following ethical approval and informed consent, 62 elite adolescent male basketball players ( $M = 16.82 \pm 0.86$  years) performed three maximal counter movement jumps (CMJ) on a force platform (Kistler, Amherst, New York). Peak power (PPactual) was compared to peak power estimated (PPest) from four previously validated regression equations (Harman et al., Sayers squat jump (SSJ), Sayers CMJ (SCMJ) and Canavan and Vescovi (CV)). Pearson product moment correlations were used to determine the relationship between PPest and PPactual. Repeated measures ANOVA was used to examine any differences (bias) between PPest and PPactual. Results Significant relationships were evident between PPest and PPactual from all four equations (all,  $P < 0.001$ ). The coefficient of determination for all four equations ranged from 48-67%. Repeated measures ANOVA showed a significant main effect ( $P < 0.001$ ). Bonferroni post hoc tests revealed that SSJ significantly underestimated power ( $P < 0.001$ ) compared to PPactual. While there were no significant differences between PPactual and Harman et al, SCMJ, and CV equations ( $P > 0.001$ ), the Harman et al equation showed the least bias (mean difference = -2.07 Watts) compared to PPactual. Discussion Results indicate that not all of the regression equations used to estimate peak power from CMJ height are appropriate to use for this cohort supporting prior claims (Duncan et al., 2008). Current results support conclusions made previously that the Harman et al equation is valid for predicting CMJ power despite being originally developed using a SJ (Sayers et al. 1999). Therefore, it can be suggested that the Harman et al. equation is best suited in this cohort as the values for PPest and PPactual were not significantly different and the discrepancy between values for PPest and PPactual was less than the other equations investigated. ## PROFILE CHARACTERISTICS OF CRITICAL MOMENTS ON BASKETBALL: GAME BALANCE AND GAME RHYTHM EFFECTS

FERREIRA, A.P., NUNES, N.

FACULTY OF HUMAN KINETICS, TECHNICAL UNIVERSITY OF LISBON

**Introduction** Ferreira (2009) has defined the situational profile of the basketball critical moments (CM) for balanced and unbalanced games on professional Portuguese basketball. However, no studies are available about the influence of game rhythm on the game criticality conditions. This study aimed to replicate the characteristics and profile determination of basketball CM, analyzing the game balance and the game rhythm effects. **Methods** Point's difference of sixty-four basketball games from the European Under-20 Championship – Division B – were reconstructed ball possession by ball possession. Each game was analyzed according the Dynamical of Coach's Thought Approach (Ferreira; 2010). CM were defined as independent objects and categorized by quarter, local in quarter, intensity, nature and the phase transition involved. Game balance was defined by a dichotomist division: balanced games, less 10 point of difference on the final score; the unbalanced games, 10 or more points between teams (Ferreira, 2009). Game rhythm was determined by the games' number of ball possessions. Using a statistical cluster analysis, game rhythm was divided into three groups: slow, moderate and fast games. Descriptive statistics were used to compare the games by balance and rhythm. An Homogeneity Analysis (HOMALS) was used to determine the specific associations among the categories in which the CM episodes were classified. Results Balanced games showed a higher number of CM during the 4th quarter than the unbalanced games ( $t=1,969$   $df=46$ ;  $p \leq 0,05$ ). The categories nature ( $\chi^2=9,549$ ;  $df=2$   $N=92$ ;  $p \leq 0,05$ ) and phase transitions ( $\chi^2=19,249$   $df=2$   $N=92$ ;  $p \leq 0,05$ ) also demonstrated significant differences on 4th quarter when balanced and unbalanced games were compared. No differences were found for the influence of game rhythm on CM characteristics. The Cronbach's Alpha average obtained on the profiling model for 4th quarter (0,70 for both dimensions) was consistent to explain the data variance of balance and unbalance games. **Discussion** These results confirm what Ferreira (2009) defined as the criticality context of 4th quarter on the balanced basketball games. The CM profile of balanced and unbalanced games emphasized the disadvantage recovering episodes with transitions from the Transition State to Alarm State and also from the Misbalance to Transition State. Fast and moderate rhythm games highlighted the beginning of the 3rd quarter as a preferential moment for critical occurrences. Ferreira, A.P.; Sampaio, J.; Volossovitch, A.; Gomes, F. (2009). 3rd International Workshop International Society of Performance Analysis of Sport, 55, University of Lincoln, 55. Ferreira, A.P., Volossovitch, A., Gomes, F., Infante, J. (2010). ## PHYSICAL, TECHNICAL FITNESS & BODY COMPOSITION PROFILE IN YOUTH BASKETBALL AGED 7-17 YEARS

MATULAITIS, K., SKARBALIUS, A.

LAPE (KAUNAS, LITHUANIA)

**Introduction** In long-term athletes development (Balyi & Williams, 2009) body composition of a basketball players and their physical, technical fitness are vital factors for managing training process (Matulaitis et al., 2010). The aim of the research was to compose physical and technical fitness normative profile for youth basketball players' (7 to 17 years). **Methods** Subjects: Basketball players aged 7-17 years

(from 30 to 172 in every age category, overall – 1051 subjects) took part in the study. Indices of body size (height, body mass), physical (speed – 20 m, leg muscle power – squat jump [SJ] and counter movement jump [CMJ]), technical fitness (dribbling, movement in defense, free throws, 1 minute shooting) were tested using well known methods of basketball (Matulaitis et al., 2010). Cross sectional analysis between age groups were assessed using independent sample t-test with unequal variance. Statistical significance was set at  $P < 0.05$ . The SPSS 17.0 for Windows software was used to form the range scale of body size, physical and technical fitness (excellent 80–100%; very good 60–79%; good 40–59%; average 20–39%; poor 0–19%). Results The greatest changes ( $P < 0.05$ ) in height were assessed in the years of 13th (5.1%) and 15th (5.2%) compared to previous years. The greatest changes ( $P < 0.05$ ) in body mass were assessed in the years of 11th (13.8%) and 15th (13.2%) compared to previous years. The power of leg muscles (SJ) increased the most ( $P < 0.05$ ) in 12th (12%) years, but CMJ in 15th (11.1%). Speed increased ( $P < 0.05$ ) in the years of 15th (6.1%). The indices of technical fitness increased ( $P < 0.05$ ) in such a way: 1 minute shooting (11th – 23.2%), dribbling (13th – 7.2%), movement and free throw (15th – 13.5% and 19.7% respectively). Discussion Genotypic and phenotypic factors might have influenced those results (Malina et al., 2004). Different changes in height and body mass of 11 and 12 year-old players might be affected by the juncture of pre-puberty and puberty (Malina et al., 2004). Increasing of SJ and CMJ, as well as technical fitness might be valuable factor for basketball coaches in order to design right training programs for improving specific fitness features for players (Balyi, 2001). ## PERSONALISED ENDURANCE TESTING IN TOP LEVEL BASKETBALL PLAYERS

RIBERA-NEBOT, D., REVERTER-MASIÀ, J.

*INSTITUTE OF HIGH PERFORMANCE CENTER (ST. CUGAT - BARCELONA), BARCELONA UNIVERSITY*

**Introduction** After more than 25 years designing specific endurance tests for basketball players and having applied them in different basketball teams (Spanish under-20 national team, young-player teams, ACB-1st div, LEB1-2nd div, LEB2-3rd div and EBA-4th div of Spanish leagues, NCAA Division I and High School of USA leagues), it is evident the need for a dynamic personalization of endurance testing. The aim of this study was to analyze the evolution of the endurance capacity, measured with personalized tests, in five professional basketball players during two consecutive seasons (LEB1 2nd division and ACB 1st division of the Spanish leagues). **Methods** One test with specific offense and defense actions for interior players (centers and power forwards) and another test with specific offense and defense actions for exterior players (point guards and forwards) in which the player had to perform the sequence of specific actions as many times as possible during four 2-minute effort periods alternated with 30-second rest periods were used to measure the endurance capacity during the first season (LEB1 2nd division). One test with specific offense and defense actions for each players (AO, FL, JP, JC, JS) consisting on eight 1.5-minute effort periods alternated with 30-second rest periods were used to measure the endurance capacity during the second season (ACB 1st division). The number of actions performed (each period and total), recovery heart rate (each 30-second rest period and at 1, 2 and 3 minutes of end) and performance index (number of actions/heart rate for each period and total) were evaluated and the test was performed six times (at beginning and end of pre-season and after three mesocycles of each season). **Results** Total number of actions and recovery heart rate at 1-minute in tests 1,2,3,4,5 and 6 are, respectively, for player AO: 225/135, 238/148, 245/136, 357/146, 370/147 and 389/144, for player FL: 216/164, 236/145, 248/153, 346/157, 372/152 and 399/153, for player JP: 220/146, 231/153, 240/149, 345/143, 365/149 and 403/161, for player JC: 236/147, 242/150, 248/156, 349/158, 364/148 and 402/140, and for player JS: 223/158, 212/135, 225/144, 330/142, 339/137 and 391/141. **Discussion** The type of endurance testing proposed, with options to personalize the type of actions and the duration and number of effort-rest periods, is useful for making effective analysis of the evolution of the endurance capacity of each player, if also other factors, such as specific training and minutes played during competition, are considered. In addition, the specific information on the endurance capacity is relevant for planning the special endurance-strength training and for effective guidance of training process. **References** Ribera-Nebot D. (1991). Endurance testing in basketball for point guards, forwards and centers. Barcelona University Report. Ribera-Nebot D. (2005). Evaluating Conditioning Capacities of Basketball Players. ## PHYSICAL FITNESS COMPONENTS ASSOCIATED WITH LINE DRILL PERFORMANCE IN ADOLESCENT BASKETBALL PLAYERS

HANKEY, J.1, LYONS, M.2, DUNCAN, M.1

*1: COVENTRY UNIVERSITY (UK), 2: NEWMAN UNIVERSITY COLLEGE (UK)*

**Introduction** Basketball entails repeated episodes of short, intense activity involving rapid changes in direction (Abdelkrim, El Fazaa and El Ati, 2007). The line drill test (LD) is proposed as a viable and appropriate field test for anaerobic performance (Seminick, 1990) due to its high reliability and acceptable validity in adolescent basketball players (Carvalho et al., 2010). The analysis of factors that influence performance in the LD has practical implications for coaches and sports scientists. This study sought to determine the components of fitness associated with performance in the LD in adolescent basketball players. **Method** Following ethical approval and informed consent, 46 elite adolescent male basketball players ( $M = 16.82 \pm 0.86$  years) took part in LDs, lateral quickness test (LQT), aerobic capacity test (VO<sub>2</sub>max estimated via 20m shuttle run), back and leg strength test (Takei Instruments Ltd), upper body strength test (Concept II Dyno), vertical jump test with measures of jump height, actual peak power (PPactual) and peak power relative to body mass (PPrel) using a force platform (Kistler, Amherst, New York). Pearson product moment correlations were used to determine the relationship between the fitness variables and LD. Multiple-regression analysis (backward stepwise;  $p$  to enter  $< 0.05$ ,  $p$  to remove  $> 0.1$ ) was conducted to determine which combination of measured characteristics could predict LD performance. **Results** Significant relationships were evident between LDs and all fitness variables (all,  $P < 0.001$ ). Multiple-regression analysis indicated that together lateral agility, aerobic capacity and PPrel could account for approximately 73.9% of the variance in LDs ( $p < .001$ ), according to the following regression formula: LD performance =  $25.291 - 0.082$  (PPrel) +  $0.795$  (LQT) –  $0.058$  (aerobic capacity). **Discussion** Performance in the LD is predicted best by a combination of factors which include PPrel, LQT and aerobic capacity rather than by any single component of fitness. As previously mentioned the LD is recommended as an appropriate field test for measuring anaerobic performance in adolescent basketball players (Carvalho et al., 2010). The results imply that aerobic capacity has a significant contribution to performance of the LD, disagreeing with previous research, which suggests the LD is an anaerobic test (Seminick, 1990). Therefore, it can be suggested that training which results in improvements in any of these factors may result in improved performance in LD. **References** Abdelkrim NB, El Fazaa S, El Ati J (2007) Br J Sports Med, 41, 69-75.

## RELATIONSHIP OF PLAYERS TO BIRTHPLACE AND BIRTHDATE AMONG JAPAN BASEBALL LEAGUE

SAKAMOTO, N.

*HYOGO COLLEGE OF MEDICINE*

Relationship of players to birthplace and birthdate among Japan baseball league Naomasa Sakamoto, Knnihiro Sakamoto, , Preventive medicine, Hyogo College of Medicine (Hyogo, Japan) Introduction : There were many reports that the birth condition especially temperature or nutrient as social environment effected to the personality and physical activity in adults, and there were reports that chronic disease might be connected with the birthdate. In this study, Japan baseball league players were analyzed on birthplace and birthdate. Method: baseball players of Central and Pacific league were analyzed on birthplace and birthdate in 780 persons using Nippon Professional Baseball Players guide 2010. Nippon sports Kikaku Shupannsha(Tokyo). The median age of players were 26 years old and the distribution of age was 19-41 years old. The birthplace was analyzed by 47 prefecture unit(Pre.). And the birthdate was analyzed by the month. The analyses was down using the odds ratio and chi-square test. Results: The distribution of blood type of the players were A type 0.374, B type 0.236, O type 0.313, AB type 0.077 as same pattern with Japanese. The median value of frequent of players per Pre. was 20 persons. Correlation coefficient(r) between the numbers of players and the populations of Pre. was 0.811. Odds ratios of the players to the populations of Pre. were high to 3.039 of Wakayama Pre. and 2.356 of Fukui Pre., and were low to 0.215 of Aomori and 0.216 of Nagano Pre.. Thus, relatively warmer south part of Japan showed relatively high frequent appearance of players, and the heavy snowed region showed low appearance of players in north part of Japan. The relation of tax rate per person per Pre. to the frequent appearance of players was analyzed. The r between numbers of players and tax amount of Pre. was 0.556. The odds ratios of players to the tax amount of Pre. were high to 2.437 of wakayama Pre., 2.034 of kyoto Pre. and 2.020 of Nara Pre., and were low to 0.171 of Aomori Pre. and 0.219 of Nagano Pre.. The distribution of birthdate of players was high in June and July. The r between birthdates of players and monthly birth rates of the population was 0.479. Odds ratios of birthdate to monthly birth rate were high to 1.561 for June and 1.512 for July, and was low to 0.475 of February and to 0.513 of March. Thus, there were tendency to concentrate the birthdate on summer season in players. Discussion: The birthplaces of professional baseball players were distributed frequently in the prefectures of relatively moderate temperature and economy rich area in Kinnki district located in middle part of Japan, The birthdate of players seemed to accumulate to June and July, and a few in February. ## EVALUATION OF PERIPHERAL VASCULAR IMPAIRMENT IN THE FINGERS OF BASEBALL PLAYERS BY USING A LASER DOPPLER BLOOD PERFUSION IMAGER

TERADA, K.1, MIYAI, N.2, NADAMOTO, M.1, NAKATANI, T.1, MIYASHITA, K.2

*1: TENRI UNIVERSITY (NARA, JAPAN), 2: WAKAYAMA MEDICAL UNIVERSITY (WAKAYAMA, JAPAN)*

Introduction Digital vessel trauma from repetitive impact on the fingers and hand is a concern for baseball players (Sugawara, 1986). Laser Doppler blood perfusion imaging (LDBPI) is a technique employing two-dimensional horizontal scanning of the blood flow in a specific tissue without the necessity for surface contact (Wärdell, 1993). The LDBPI method may have the benefit of detecting vasospastic abnormalities and occlusion of the digital artery, which generally appear with an inhomogeneous reaction to cold. This study aimed to examine whether LDBPI is useful for detecting peripheral vascular impairment in baseball players exposed to repetitive impact due to catching a ball. The changes in finger skin blood flow in response to a cold water immersion test were evaluated using LDBPI in baseball players suffering from disturbances of finger peripheral circulation and in healthy players without the symptoms. Subjects and Methods The subjects were 10 male university baseball players (age, 18-21 years) suffering from peripheral vascular impairment of the index finger on the catching side and 22 healthy players of a similar age as controls. A cold provocation test was carried out by immersing a subject's hand on his catching side into cold water at a temperature of 10°C for 10 minutes. Repeated image scanning of skin blood flow on the palm was performed every 2 min before, during, and after cold water immersion using a PIM-3 LDBPI (PERIMED, Sweden). The mean blood perfusion values in the finger area were calculated on each color-coded image. The finger skin temperature was recorded using an electrode thermistor attached to the skin on the dorsal side of the index finger. Results The cold provocation test showed that the finger skin temperature was not significantly different between the symptomatic players and controls. However, mean blood perfusion values were significantly different between the controls and the symptomatic players at almost every measurement point. The difference in the responses of skin blood perfusion under the condition of cold provocation between the symptomatic players and controls were clearly demonstrated in color-coded images. Discussion These findings suggest that the LDBPI technique employing multiple point recording and spatial mapping is an important quantitative tool for studying changes in finger skin blood perfusion after cold water immersion. Thus, this method can be used for the assessment of peripheral circulatory function in baseball players.

## ACUTE INFLUENCE OF MONOCULAR VISION ON SPECIFIC SKILLS IN HANDBALL – A PILOT STUDY

LENZ, F., WUNSCH, P., LÜNING, S., KITTMANN, V.

*RUHR-UNIVERSITY BOCHUM*

Introduction: The quality of vision in high-performance sport is a basic requirement to react on steady changing game situations. The visual system is an essential condition for performances in sports with differences in binocular and monocular visual function (left and right). Numerous athletes have on-sided visual impairments, very often they remain undetected. The present study examines the influence of on-sided visual impairments on game skills in Handball. Methods: 11 physical education students took part in our study (age: 21.91±1.13 years; 9 male and 2 female, Visus L: 1.59±0.24; R: 1.64±0.22). Every subject performed four handball-specific tests on one experimental day, catching quotas in ten levels 20km/h -84km/h quantity 0-10 (1), pass quality in terms of precision in points-based system 0-5(2.1) and speed in km/h (2.2), slalom dribbling in sec(3) and depth perception in cm(4). The test were conducted in crossover-design without distraction of the visual function (BI) and only monocular right (MOR) or monocular left (MOL) seeing. Results: In catching quotas we found a significant impairment between BI and MOR(p=0.023)and BI and MOL(p=0.181) (1)BI:5.18±1.41;MOR:3.64±1.69;MOL:3.27±2.41(p=0.014).In the testsituation, which analyses the pass quality and precision we found no changes (2.1) BI:39.18±5.49; MOR:36.18±8.37;MOL:37.27±3.52(p=0.284)(2.2)BI:63.93±5.6;MOR:63.25±5.76;MOL:63.13±5.34(p=0.579).There were no changes in slalom dribbling time for all testsituations (3) BI:7.47±0.50; MOR:7.73±3.55;MOL:7.59±0.50(p=0.331).In

depth perception we found a significant impairment in BI and MOR ( $p=0.074$ ) and BI and MOI ( $p=0.02$ ) (4) BI:  $1.81 \pm 1.77$ ; MOR:  $11.09 \pm 10.24$ ; MOI:  $18.36 \pm 13.92$  ( $p=0.009$ ). Discussion: The reduction of the monocular visual function leads in our study to a deterioration on game skills in handball especially on standard game situations in mid-tempo, this shows especially test no. 1 and test no. 4, which represent essential parts of the handball game. Undetected visual impairments will lead, with a high probability, to a significant loss of performance, because our results show how the visual function and our tested game skills get significant worse if the subject is monocular. Unanswered is the question of compensation and possibilities of specific training. Prospectively it is still to examine if a monocular practice leads to an optimization of binocular visual performances in sports. Literature: Olivier, I., Weeks, D.-J., Lyons, J., Ricker, K.-L., Elliot, D. (1998). ## INSTRUMENTS FOR FATIGUE'S CONTROL IN HANDBALL TEAM PLAYERS IN ECOLOGICAL SITUATIONS: CMJ AND 10 M SPRINT TIME.

ORTEGA-BECERRA, M.1, JIMÉNEZ-REYES, P.2, PÁRRAGA-MONTILLA, J.A.3, MORCILLO-LOSA, J.A.3

1: US (SEVILLA, ESPAÑA), 2: UAX (MADRID, ESPAÑA), 3: UJA (JAÉN, ESPAÑA)

Introduction In handball team, the possession or not of the ball it determines the own player's behaviors, existing a constant relation offensive - defense that takes place during the game. This correlation implies that the actions players realize are characterized by rapid direction changes, accelerations, sprints, jumps and throws, all of them performed to high intensity and opposite to an opponent what implies that the handball team players develop high degrees of fatigue specially in muscles' legs (Ronglan, Raastad and Borgesen, 2006). Therefore the aim of this study is acquiring more specific knowledge regarding development of fatigue following real handball matches. Such sport specific knowledge may facilitate the adjustment of more adequate training and competition procedures within elite handball. Methods Sixteen male players from Spanish First Division (age  $25.6 \pm 4.4$  yr, body mass  $86.3 \pm 7.9$  kg, height  $184.4 \pm 14.6$  cm; body fat  $12.7 \pm 8.2\%$ ) participated in this study. They realized 5 counter-movement jumps (CMJ) and 10 m. sprint test just after finishing the warming and before the celebration of match, these measures were repeated at the half and the end of match. Results We analyse CMJ height and 10 m. sprint time losses during four official matches. There were significant differences between CMJ height loss ( $p < 0.001$ ) before and after match and between 10 m sprint time loss ( $p < 0.005$ ) before and after match. Furthermore, these differences also were found between first and second half of the match. Discussion During the match development the players are fatiguing measured like CMJ height loss and the increase in time to travel 10 m. During the measurements realized at half time of and at the end of match, being this reduction even more accused in the last measurement. Therefore, it is possible to conclude that the use of the CMJ and 10 m. sprint time are valid and reliable tools for estimating the neuromuscular fatigue produced (Jiménez-Reyes, 2010). ## THE EFFECTS OF MENSTRUAL CYCLE PHASE ON THE DEVELOPMENT OF PEAK TORQUE UNDER ISOKINETIC CONDITIONS

GORDON, D.1, HUGHES, F.2, YOUNG, K.2, KEILLER, D.1, SCRUTON, A., BARNES, R.2

1: ANGLIA RUSKIN UNIVERSITY, 2: CAMBRIDGE UNIVERSITY

Introduction: It is widely recognised that during the menstrual cycle there are decrements in athletic performance. However the association between menstrual cycle phase and the rate of force development is less well understood. Therefore the purpose of this study was to examine the effects of menstrual cycle phase on the development of peak torque across a range of isokinetic speeds. Methods: Following local Institutional ethics approval 17 well trained female participants agreed to participate. 11 of the participants formed the non-oral contraceptive group (n-OC) (age  $20.7 \pm 1.4$  yrs, mass  $59.2 \pm 6.9$  kg, height  $166.8 \pm 7.1$  cm) and reported a regular menstrual cycle. The remaining 6 participants formed the oral contraceptive control group (OC) (age  $20.3 \pm 0.5$  yrs, mass  $60.5 \pm 4.2$  kg, height  $164.8 \pm 4.8$  cm). Concentric strength of the knee flexors and extensors were assessed using an isokinetic dynamometer at speeds of 60 °/s, 120 °/s, 180 °/s and 240 °/s with the participant completing 5 repetitions at each speed separated by a recovery period of 180 s. The participants completed this protocol on four occasions which corresponded to menstruation (MEN), mid-follicular (mFOL), mid-luteal (mLUT) and immediately pre-menstrual (pMEN). Also recorded from the non-OC group at the onset of each visit to the laboratory were progesterone and 17β-oestradiol via enzyme immunoassay. Results: There was a significant decrease in peak torque production (Nm) of the extensors for non-OC at 120 °/s ( $P = 0.0207$ ) (MEN) and of the flexors at 60 °/s ( $P = 0.0116$ ) (MEN) and 120 °/s ( $P = 0.0282$ ) (MEN). There was no significant difference for peak torque development across menstrual cycle phase for the OC group ( $p > 0.05$ ). Re-analysis of the data using test order instead of menstrual phase indicated that there was no learning effect on peak torque production of the knee flexors or extensors in both the non-OC and OC groups ( $p > 0.05$ ). There was a significant increase in progesterone (pg/ml) during mLUT compared to MEN and mFOL ( $P = 0.0010$ ) and a significant decrease in oestrogen during MEN compared to mLUT ( $P = 0.0207$ ). Discussion: The decrease in peak torque production at 60 and 120 °/s would appear to be associated with decreased oestrogen concentrations. The data suggests that it is the amount of force produced by the muscle fibres rather than fibre recruitment patterns that are affected by stage of menstruation as evidenced by no change in peak torque at 180 and 240 °/s. Oestrogen receptors have been shown in skeletal muscle suggesting that oestrogen could have a direct effect on force production. Furthermore high oestrogen levels have been associated with increased availability of ATP and PCr.

### COMPARISON BETWEEN YOUNG AND POSTMENOPAUSAL WOMEN FOR CHANGES IN MARKER OF MUSCLE DAMAGE FOLLOWING TWO DIFFERENT VELOCITIES OF ECCENTRIC EXERCISE

GASPARI, A., NOGUEIRA, F., Vechin, F., CONCEIÇÃO, M., BERTON, R., FERRARI, S., BONGANHA, V., LIBARDI, C., MADRUGA, V.A., CHACON-MIKAHIL, M.P.T.

STATE UNIVERSITY OF CAMPINAS - BRAZIL

**Introduction** It is known that unaccustomed eccentric exercise induces muscle damage (Lavender and Nosaka, 2006). Some parameters could influence in this process, such as age (Dedrick and Clarkson, 1990) or contraction velocity (Chapman et al., 2006). This study investigated if different velocities of eccentric exercise could interfere in the magnitude of losses and repair of isometric strength (IS) in postmenopausal women when compared to young women. Isometric strength is the best marker for muscle damage (Warren et al., 1999), therefore, one can infer that greater losses of IS indicates greater muscle damage. We hypothesize that fast eccentric actions should promote greater losses in IS for both groups, with greater muscle damage for the postmenopausal group. **Methods** 19 young and 18 postmenopausal (PM) women volunteered for the study, divided into 4 groups, 2 of fast velocity ( $210^{\circ} \text{ s}^{-1}$ ): young fast (YF,  $n=10$ ) and postmenopausal fast (PMF,  $n=10$ ); and 2 of slow velocity ( $30^{\circ} \text{ s}^{-1}$ ): young slow (YS,  $n=9$ ) and postmenopausal slow (PMS,  $n=8$ ). The groups performed 5 sets of 6 maximal isokinetic eccentric actions (Biodex System 4 Pro, Medical Systems, USA) of elbow flexors in the non-dominant arm. The maximal isometric muscle strength (IS) was assessed before the session of eccentric exercise (Pre), immediately after (Post), and 24, 48, and 72h after the protocol. **Results** No significant difference was found at IS nor between ages or velocities. However, IS values were different in YS, YF and PMS throughout the moments. Pre values were significantly higher from: 24h ( $p < 0.044$ ) and 48h ( $p < 0.005$ ) for YS; 24h ( $p < 0.003$ ) and 72h ( $p < 0.024$ ) for YF; Post ( $p < 0.001$ ), 24h ( $p < 0.017$ ), 48h ( $p < 0.001$ ) and 72h ( $p < 0.001$ ) for PMS. No significant difference was found in PMF. **Discussion** It is known that estrogen could possibly attenuate muscle damage (Kendall and Eston, 2002). Despite the PM state of the group, and thus the reduced protection of estrogen, no changes were observed in the IS values between ages. What concerns velocity, we expected that fast velocity would promote greater muscle damage in men (Chapman et al., 2006). In the present study the velocity did not affect IS. **In conclusion**, for women, we found no influence of age or velocity in this marker of muscle damage. **References** Chapman D, Newton M, Sacco P, Nosaka K. ### EFFECTS OF QUASI FOLLICULAR AND QUASI LUTEAL PHASE-BASED STRENGTH TRAINING ON MUSCLE CELL PARAMETERS IN SUBJECTS WITH ORAL CONTRACEPTION

SUNG, E.I., HAN, A.I., HINRICHS, T.I., VORGERD, M.2, PLATEN, P.I

IRUHR-UNIVERSITY BOCHUM

**Purpose:** The modern monophasic oral contraceptive (OC) administration consistently suppresses circulating endogenous sex steroid hormone concentrations in OC users. OC provide the women with fixed doses of estrogen and progestogen over 21 days (consumption phase), followed by a 7 days break (withdrawal phase). These hormone concentrations might be important influence factors on strength capacity. The aim of this study was to investigate effects of quasi follicular phase-based (qFT) in comparison to quasi luteal phase-based strength training (qLT) on cellular parameters such as muscle fiber composition, diameter and cell nuclei to fiber ratio of skeletal muscle. **Methods:** Six healthy untrained or moderately trained women (age:  $22.8 \pm 3.0$  yrs, height:  $164.5 \pm 5.09$  cm, weight:  $65.0 \pm 10.0$  kg) using OC completed a strength training program of the m. quadriceps femoris for each leg on the leg press for 3 menstrual cycles (12 weeks). The subjects trained (4 time a week) one leg mainly in quasi follicular phase (qFO) and the other leg mainly in quasi luteal phase (qLU). Muscle fiber composition (F%no: relative fiber number, F%area: relative fiber area), muscle fiber diameter (Fdm) and cell nuclei to fiber ratio (N/F) were determined in skeletal muscle biopsy samples of both legs (m. vastus lateralis) prior to and after 3 months of strength training using histochemical analysis (ATPase and HE staining). **Results:** F%area of type II increased after 3 months strength training of qFT ( $+7.0\% \pm 10.9$ ) and qLT ( $+6.7\% \pm 13.3$ ). Mean value of F%no of type II increased by  $7.0\% \pm 7.5$  after qFT and by  $1.0\% \pm 11.0$  after qLT. Moreover, Fdm showed increases in type II after both qFT ( $+5.1 \pm 8.8\mu\text{m}$ ) and qLT ( $+6.6 \pm 7.8\mu\text{m}$ ). N/F ratio increased after qFT ( $+0.6 \pm 0.7$ ) and decreased after qLT ( $-0.1 \pm 0.6$ ). **Conclusions:** In a small sample of 6 subjects we were not able to demonstrate any relevant differences between the two training modes concerning adaptation of skeletal muscle. This finding will have to confirm in larger sample, which might be explainable by the artificially constant hormone levels in OC users. The confirmation of this finding would suggest that untrained or moderately trained OC users could perform strength training independently from phases of menstrual cycle. **Acknowledgement** The study was supported by the Federal Institute of Sport Science Bonn, Germany (BISp: IIA1-070106/09-10).

### TRAINING STATUS AND SKIN MICROVASCULAR VASODILATION IN ADOLESCENT FEMALES

ROCHE, D.M., HOLLOWAY, K., MARWOOD, S., GARRARD, M., UNNITHAN, V.B.

LIVERPOOL HOPE UNIVERSITY

**Introduction** Detrimental vascular changes begin in youth and are seminally characterised by endothelial dysfunction. Therefore, the procurement of systemically intact endothelial function from a young age is pivotal in the prevention of atherosclerotic morbidity. We have previously reported superior endothelial vasodilatory responsiveness of the skin microcirculation in the limbs of trained versus untrained male adolescents (Roche et al., 2010). However, no study has exclusively investigated the vasodilatory responsiveness of the skin microcirculation in healthy young females in relation to training status. **Methods** 14 trained and 9 inactive females ( $\text{VO}_{2\text{peak}}$ :  $43.7 \pm 3.4$ ;  $35.3 \pm 4.2$  mL/kg/min,  $p < 0.01$  respectively), matched for maturity status (age:  $15.0 \pm 0.8$  yrs; tanner stage:  $3.8 \pm 0.98$ ; mass:  $55.7 \pm 7.8$  kg; stature  $160.7 \pm 4.6$  cm), had their skin microcirculation interrogated via laser Doppler flowmetry (Periflux 5000) on the forearm and dorsal foot. Maximal skin blood flow (SkBFmax) was attained by heating the skin to 44 degrees using integrated probe heaters, whilst peak forearm post-occlusive reactive hyperaemia (PORH) was determined as the highest blood flux value following the rapid deflation of a cuff (50mmHg above systolic blood pressure for 3 mins). Peak  $\text{VO}_2$  was assessed through a maximal treadmill test to volitional exhaustion. Between group comparisons were made using independent t-tests. Maximal cutaneous vascular conductance, during the thermal plateau (CVCmax), was calculated as  $\text{SkBFmax}/\text{MAP}$  (mean arterial pressure). **Results** SkBFmax was significantly higher in the skin of the dorsal foot of trained girls (trained:  $293.9 \pm 139.7$ , inactive:  $186.6 \pm 75.4$  PU,  $p < 0.05$ ). Likewise foot CVCmax was significantly higher in the trained versus inactive girls (trained:  $3.8 \pm 1.45$ , inactive:  $2.8 \pm 1.8$  PU/mmHg,  $p < 0.05$ ). In the forearm, SkBFmax, CVCmax and PORH did not vary significantly between groups (SkBFmax trained:  $267.4 \pm 139.5$ , inactive:  $211.4 \pm 124.5$  PU; CVCmax trained:  $3.4 \pm 1.7$ , inactive:  $2.8 \pm 1.8$  PU/mmHg; PORH trained:  $55.3 \pm 46.7$ , inactive:  $34.6 \pm 19.4$  PU). **Discussion** We have demonstrated that in healthy adolescent girls,

regular physical training that is sufficient to elevate  $\text{VO}_{2\text{peak}}$  is associated with superior maximal endothelial vasodilation and cutaneous vascular conductance, at least in dorsal foot skin microcirculatory tissue. This has implications regarding the remedial role of physical activity from a primary prevention stand-point in healthy young females. ### EFFECTS OF MENSTRUAL CYCLE PHASE AND EXERCISE TRAINING TYPE ON CENTRAL ARTERIAL COMPLIANCE IN YOUNG WOMEN

HAYASHI, K., MIYACHI, M., SUGAWARA, J., KOMINE, H., YOKOI, T., ONODERA, S., MESAKI, N.

KOKUGAKUIN UNIVERSITY

[Introduction] Decreased central (e.g., carotid and aorta) arterial compliance with aging is an independent risk factor for mortality and morbidity of cardiovascular diseases. Though estradiol and progesterone, major ovarian hormones, have potentials for changing arterial compliance, the effects of their natural fluctuations during the menstrual cycle are not fully understood. Meanwhile, in young men, regular aerobic exercise increases arterial compliance, but it is decreased by resistance training (Otsuki et al., 2007). However, little data related to the exercise training type on arterial compliance are available in young women. In this study, we determined whether carotid arterial compliance is affected by menstrual cycle phases (study 1) and/or regular exercise training (aerobic or resistance training) (study 2). [Methods] Study 1; Ten eumenorrheic sedentary healthy women (mean age: 20.7 yrs.) were studied. We investigated variations in blood pressure (carotid and brachial), carotid arterial compliance (simultaneous ultrasound and applanation tonometry) and serum estradiol and progesterone concentrations at the five different crucial hormonal time points during the menstrual cycle (menstrual: M, follicular: F, ovulatory: O, early luteal EL, late luteal: LL). Study 2; we determined the relation between the exercise training type and the carotid arterial compliance in healthy young women: 26 healthy young women who were sedentary (CO, n=9), endurance-trained (ET, n=9), and resistance-trained (RT, n=8) groups. [Results] Study 1; Carotid arterial compliance varied cyclically, with significant increase from M and F to O phase, and sharp falls in the EL and LL phase ( $F=5.590$ ,  $p<0.05$ ). The fluctuation in carotid arterial compliance was synchronized with the changes in the balance of blood estradiol and progesterone concentrations. Study 2; No significant difference was found in the carotid arterial compliance among the ET, RT, and CO groups. [Conclusion] These results suggest that it is necessary to consider the menstrual cycle phase rather than exercise training status when interpreting arterial elasticity in young women. ### THE EFFECT OF EXERCISE AND/OR TESTECTOMY ON CONCENTRATIONS OF ADIPONECTIN AND TESTOSTERONE IN BOTH BLOOD AND ADIPOSE TISSUE

KIMURA, M., MATSUSHITA, Y., KUSAKABE, R., TAKIUE, Y., HOSOYAMADA, M., SAITO, H.

KEIO UNIV.

INTRODUCTION and PURPOSE There is little evidence that the effect of exercise and/or testectomy on production and secretion of adiponectin from adipocyte. The purpose of this study was to investigate the effect of exercise and/or testectomy on concentrations of adiponectin and testosterone in both blood and adipose tissue. MATERIALS and METHODS Male Wistar rats were used in this study (12-week-old at the end of experiment). The rats were randomly assigned to either the 3 weeks voluntary wheel running exercise (Ex-) or sedentary control (Co-) groups. Both groups had testectomy (-Tx) and sham (-Sh) operation groups. All rats subjected to these operations at 8-week-old, and took one week of recovery and acclimatization period. The cages of exercise group attached freely accessible running wheels with digital revolution counters, but access to the wheel was prohibited during the recovery and acclimatization period. The rats were provided with water and standard chow food ad libitum. At the end of experimental period, blood and fat tissue samples were collected and analyzed using enzyme immunoassay methods. RESULT and DISCUSSION Testectomy provided remarkable decreases in blood testosterone concentrations in both Co-Tx and Ex-Tx groups. Compared to Co-Sh group, Co-Tx group exhibited the significant increase in blood adiponectin concentration and the tendency to decrease in adiponectin and testosterone concentrations in adipose tissue. Ex-Sh group did not show any significant changes in these parameters. Compared to Co-Tx group, Ex-Tx group exhibited the decrease in blood adiponectin concentration and the tendency to increase in adiponectin and testosterone concentrations in adipose tissue. These findings may indicate that testosterone in adipose tissue negatively regulate adiponectin secretion from adipocyte.

### SEX DIFFERENCES IN ELECTROMECHANICAL DELAY OF THE HAMSTRINGS DURING ECCENTRIC MUSCLE ACTIONS

DE STE CROIX, M., EL NAGAR, Y., JAMES, D.

UNIVERSITY OF GLOUCESTERSHIRE

SEX DIFFERENCES IN ELECTROMECHANICAL DELAY OF THE HAMSTRINGS DURING ECCENTRIC MUSCLE ACTIONS De Ste Croix, M., El Nagar, Y. and James, D. University Of Gloucestershire, Department of Sport and Exercise, Gloucester, UK Introduction Increased relative risk of non-contact ACL injury has been attributed to numerous biomechanical, anatomical and neuromuscular factors. One of the proposed reasons for an greater incidence of non-contact ACL injury in females is a reduced capacity for neuromuscular functioning to stabilise the knee joint effectively (Hewett et al. 2007). Therefore the purpose of this study was to examine sex differences in the electromechanical delay (EMD) of the hamstring muscles during eccentric muscle actions. Methods One hundred and ten participants (55 males and 55 females) provided written informed consent to participate in the study. Prone isokinetic eccentric torque of the hamstrings was determined at 60, 120, 240°/s with the hip flexed at 0°. Range of movement of the knee joint was 90°. Surface electromyography was simultaneously recorded from the semitendinosus (ST), semimembranosus (SM) and biceps femoris (BF) of the dominant limb using an 8-channel DelSys EMG telemetry system. The biodex square wave synchronization pulse was configured with the EMG software via a trigger system so that EMG and torque data were completely time aligned. EMG data were collected at a sampling frequency of 1024 Hz and included a common mode rejection ratio of <80 dB and an amplifier gain of 1000. Raw EMG data was band pass filtered at 20 – 450 Hz. EMD was determined as the time delay between the onset of muscle activation (change in activation of +15  $\mu\text{V}$ ) and onset of torque production (9.6Nm) according to the procedures described by Zou et al (1995). A 2 (sex) X 3 (muscle group) X 3 (movement velocity) ANOVA was performed with subsequent post hoc analysis using bonferroni correction. Results There were no significant differences between the EMD of the 3 muscles examined at any of the movement velocities ( $p>0.05$ ). EMD for all muscles significantly increased with increasing movement velocity ( $p<0.05$ ). Irrespective of muscle examined or movement velocity no sex differences were found ( $p>0.05$ ). Discussion During eccentric hamstring muscle actions there are no differences in the delay time of the 3 muscles examined indicating these 3 hamstring muscles activate at a similar rate. Irrespective of sex, as movement velocity increases the delay time also increases indicating a reduced

capacity to stabilise the knee during fast velocity movements with potential for increased risk of injury. We found no significant sex differences in EMD irrespective of movement velocity or muscle examined, suggesting that females do not have impaired neuromuscular performance of the hamstring compared with males during eccentric hamstring muscle actions. References Hewett, T., Shultz, S., and Griffin, L. (2007) Understanding and preventing non-contact ACL injuries. *Human Kinetics*

### **MENSTRUAL CYCLE PHASE AND ORAL CONTRACEPTIVE USE: NO EFFECT ON ENDURANCE PERFORMANCE IN ROWERS**

VAIKSAAR, S.

UNIVERSITY OF TARTU

**MENSTRUAL CYCLE PHASE AND ORAL CONTRACEPTIVE USE: NO EFFECT ON ENDURANCE PERFORMANCE IN ROWERS** Vaiksaar, S.I, Jürimäe, J.I, Mäestu, J.I, Purge, P.I, Jürimäe, T.I 1: UT (Tartu, Estonia). Introduction Oestrogen and progesterone fluctuate predictably across the menstrual cycle (MC) in normally cycling eumenorrhoeic women (Oosthuyse & Bosch, 2010). The oral contraceptive (OC) use may provide a more stable environment to evaluate the effect of reproductive hormones on physiological variables and exercise performance in women (Rechichi et al., 2009). The aim of this study was to examine whether variables commonly used in aerobic exercise testing to predict performance over 2000 m distance are influenced by MC phase and OC use in female rowers. Methods Twenty-four eumenorrhoeic female rowers distinguished on the basis of both menstrual status and athleticism participated in this study and were divided into competitive cyclic athletes (CCA; n=8), recreationally trained cyclic athletes (RCA; n=7) and recreationally trained athletes taking oral contraceptive (OC) pills (ROC; n=9). Rowers performed two incremental tests on a rowing ergometer during two different phases of the MC: the follicular phase (FP) and the luteal phase (LP). The study variables were power output (Pa), heart rate (HR), oxygen consumption (VO<sub>2</sub>), carbon dioxide production (VCO<sub>2</sub>), minute ventilation (VE), the mean respiratory exchange ratio (RER), and ventilatory equivalents of O<sub>2</sub> (VE/VO<sub>2</sub>) and CO<sub>2</sub> (VE/VCO<sub>2</sub>), which were measured at maximal and at the aerobic-anaerobic transition intensities. In addition, maximal blood lactate (La) values after the test were obtained. Results When comparing Pa, VO<sub>2</sub>, HR and La values, no significant differences ( $p>0.05$ ) between FP and LP at maximal load and at threshold intensity were found in all three groups of studied rowers. However, we observed higher values ( $p<0.05$ ) for VE/VCO<sub>2</sub> at both intensities in LP compared with FP in ROC group. Discussion Similarly to other studies, no effect of MC phase on P<sub>max</sub>, VO<sub>2max</sub> and HR<sub>max</sub> values were found in highly active women with normal MC (Forsyth & Reilly, 2005). Although the glycogen-sparing effect of oestrogen in the LP may cause a decrease in La production in muscle during exercise (Forsyth & Reilly, 2005), MC phase did not affect aerobic-anaerobic transition intensity at least in more trained athletes. However, some cyclical variations in ventilatory response should be considered when interpreting physiological test results in OC users. Therefore, normally menstruating rowers and rowers taking OC pills should not be concerned about the timing of their MC with regard to optimized sport-specific endurance performance. ### **PET OWNERSHIP AND MATERNAL ACTIVITY DURING PREGNANCY**

WESTGARTH, C.I, LIU, J.2, HERON, J.3, NESS, A.3, BUNDRED, B.I, GASKELL, R.I, COYNE, K.I, GERMAN, A.I, MCCUNE, A.A, DAWSON, S.I

1. UNIVERSITY OF LIVERPOOL

**PET OWNERSHIP AND MATERNAL ACTIVITY DURING PREGNANCY** Westgarth, C.I, Liu, J.2, Heron, J.3, Ness, A.3, Bundred, B.I, Gaskell, R.I, Coyne, K.I, German, A.I, McCune, A.A, Dawson, S.I 1: University of Liverpool (Liverpool, UK), 2: University of South Carolina (Columbia, USA), 3: University of Bristol (Bristol, UK), 4: WALTHAM Centre for Pet Nutrition (Melton Mowbray, UK) Introduction Maternal obesity has adverse outcomes for both mothers and their offspring, which have led to recent guidance that clinicians should advise pregnant women to manage their weight and to exercise (Sayburn, 2010). The objective of this study was to examine whether pregnant women that own pets, in particular dogs, were more active and less likely to be obese, than those who did not. Methods Data came from a cross sectional analysis of 14,273 pregnant women enrolled in the Avon Longitudinal Study of Parents and Children (ALSPAC) in the UK. The main outcome measures were self reporting of strenuous (enough to work up a sweat) activity (hours per week) at 18 weeks of gestation, types and hours spent in leisure-time physical activities, and maternal overweight defined as pre-pregnancy BMI = or above 25 and obese BMI = or above 30. The assumption was made that pre-pregnancy BMI was a proxy for weight status during pregnancy. Pet ownership was self reported at 8 weeks gestation. Logistic regression models were used, with adjustment for confounding factors known to be associated with pet ownership, activity and weight status. Results There was evidence for a positive relationship between participation in activity at least once a week and dog ownership (OR=1.27, 95% CI=1.11-1.44,  $P<0.001$ ). Dog owners were 50% more likely to achieve the recommended 3 hours activity per week, equivalent to 30 minutes per day, most days of the week (OR=1.53, 95% CI=1.35-1.72,  $P<0.001$ ). Dog owners were more likely to participate in brisk walking activity than those who did not have a dog, (compared to none; 2-6 hrs per week OR=1.43, 95% CI=1.23 to 1.67; 7+ hrs per week OR=1.80, 1.43 to 95% CI=2.27). No association was found between dog ownership and participating in other types of activities such as jogging, keep fit classes or swimming. There was no evidence of an association between dog ownership and weight status pre-pregnancy. Discussion Pregnant women who own dogs were more likely to be active, particularly through brisk walking but were no less likely to be obese (based on pre-pregnancy BMI). Walking is considered a low risk exercise and it is a readily available and economical. Although the effect sizes were modest, encouraging people to walk their dogs might help to increase activity levels in pregnant women. Further work needs to examine the motivation and barriers to owning and walking dogs in pregnancy. References Sayburn, A. (2010) Challenge pregnant women to manage their weight, NICE says. *British Medical Journal*, 341(c4107).

### **LIFESTYLE AND HOMA INDEX IN POST-MENOPAUSE**

DI DONATO, F., DI BLASIO, A., IZZICUPO, P., D'ANGELO, E., BUCCI, I., NAPOLITANO, G.

CHIETI-PESCARA UNIVERSITY

**Introduction** Menopause is characterised by both hormonal and metabolic changes linked with an increased risk of cardiovascular disease. Insulin resistance increases the cardiovascular risk, and it has been shown linked to a negative lifestyle, including poor movement and bad dietary habits. To better know whether movement and diet are negatively affected by the same problems (i.e. qualitative, quantitative or distributive problems) or not, the aim of our study was to individualize the influencing factors of the onset of insulin resistance in post-menopausal women without counselling on diet and daily movement. **Methods** Eighty-four post-menopausal women were

enrolled in the study, the 47 of them ( $57.34 \pm 4.78$  yrs) without history of diabetes mellitus, cardiovascular diseases, hormone-replacement therapy, controlled diet and physical exercise program participation were used for the analysis. Body composition was assessed by electrical bioimpedance technique, while the SenseWear Pro3 Armband measured daily physical activity characteristics. The device gives information about mean values of daily energy expenditure, intensity of daily physical activities (METs m/die), daily steps (STEPS m/die) and both time (TPA m/die) and energy spent (PAEE m/die) on physical activities with intensities  $> 3$  METs. A dietician estimated dietary habits and calories intake from three-day dietary records. The sum of kcal intake with breakfast, morning snack and lunch (FIRST%) gave information about energy intake of the first part of the day as percentage of daily energy intake. The sum of kcal intake with afternoon and evening snacks, and dinner (SECOND%) gave information about energy intake of the second part of the day. Maximal stress test was performed to assess maximal aerobic capacity (Max METs). Blood was collected to measure plasma glycaemia and insulin. HOMA index was calculated to assess insulin-resistance. Results Pearson's correlation showed the HOMA index positively correlated with body weight, BMI, waist circumference (WC), waist to hip ratio, percentage fat mass, SECOND% and dinner energy intake, expressed as percentage of daily energy intake. On the contrary, METs m/die, STEPS m/die, PAEE m/die, TPA m/die and FIRST% have been found inversely correlated with HOMA index. Linear regression, performed in stepwise modality ( $F=11.637$ ,  $p<0.001$ ), indicated WC ( $p=0.010$ ), SECOND% ( $p=0.005$ ) and STEPS m/die ( $p=0.005$ ) as predictive variables of HOMA index. Discussion Visceral adiposity, quantity of daily physical activity and the way to share daily energy intake between first and second part of the day are useful to predict insulin resistance of postmenopausal women, and suggest useful fields of intervention to promote health and to prevent cardio-metabolic diseases.

### **NO RELATIONSHIP BETWEEN TESTOSTERONE OR MACRONUTRIENT INTAKE WITH MUSCLE STRENGTH AND SIZE CHANGES DURING 12 WEEKS OF ELBOW FLEXOR STRENGTH TRAINING**

HANSON, B., ERSKINE, R.M., FLETCHER, G., FOLLAND, J.P.

LOUGHBOROUGH UNIVERSITY.

**Introduction** There is considerable individual variability in the muscle strength and size adaptations to resistance training (RT) that may be influenced by testosterone and dietary intake of protein and fat. This study investigated the relationship between macronutrient intake and basal testosterone with changes in muscle strength and size over 12 weeks of elbow flexor RT. **Methods** Thirty-three untrained healthy males (18-30 yr) took part in 12 weeks of RT; 2-3 sets each of unilateral and bilateral elbow flexor curls at 8-10 repetition maximum (RM) 3 x per week. They were randomly assigned to a protein (PRO; 20g protein, 7g carbohydrate (CHO), 250ml H<sub>2</sub>O; n=17) or placebo (PLA; 7g CHO, 250 ml H<sub>2</sub>O; n=16) drink taken immediately before and after each RT session. Pre and post RT muscle strength (isometric elbow flexion strength (IEFS) at 120°, 1RM) and size (elbow flexor volume (FVOL), anatomical cross-sectional area (ACSA) of the biceps brachii, brachialis and brachioradialis muscles, determined from magnetic resonance imaging (MRI)) measurements were made of the dominant arm. Participants completed a 3-day weighed food intake during the 5th week of RT. Total testosterone (TT) and sex hormone binding globulin (SHBG) from fasted, early morning blood samples pre and post RT were measured by ELISAs and used to calculate free testosterone (FT). Pearson's correlation coefficient was used to assess bivariate relationships (critical p value  $<0.05$ ). **Results** RT increased IEFS (263 to 298 N;  $13.4 \pm 9\%$ ); 1RM (12.8 to 17.8 kg;  $49.3 \pm 19.7\%$ ); FVOL (401 to 463 cm<sup>3</sup>;  $15.7 \pm 6.1\%$ ); ACSA (28 – 32 cm<sup>2</sup>;  $16.3 \pm 5.7\%$ ) respectively ( $p<0.01$ ). Training adaptations were not influenced by PLA or PRO supplementation. Therefore, both groups were subsequently considered together for further analysis. Testosterone fractions were unaffected by the RT (TT, FT:  $p>0.18$ ) and therefore the mean was used for subsequent analysis. There were no associations between TT and FT and changes in measures of muscle strength and size after RT (IEF, 1RM, FVOL, ACSA:  $R<0.15$ ,  $P>0.43$ ). No relationships were found between macronutrient intake expressed as g.kg<sup>-1</sup> or % energy intake and changes in muscle strength and size (protein, SFA, PUFA, MUFA;  $R<0.09$ ,  $P>0.07$ ). There were also no correlations between TT or FT with PUFA, SFA, MFA and protein intake (all:  $R<0.09$ ,  $P>0.4$ ). **Discussion** In the current study, serum testosterone and macronutrient intake did not influence the muscle strength and size gains that occurred with RT in healthy young men. Other factors, including as local paracrine hormones and genetics, may be more important in explaining the individual responses to RT. **Acknowledgement** This study was sponsored by GlaxoSmithKline Nutritional Healthcare.

### **EFFECTS OF AEROBIC EXERCISE ON URINARY ESTROGENS AND PROGESTAGENS IN POSTMENOPAUSAL WOMEN.**

TIMON, R., ROBLES, M.C., TORIBIO, F., BRAZO, J., OLCINA, G., MAYNAR, M., MAYNAR, J.I.

SPORT SCIENCES FACULTY. UNIVERSITY OF EXTREMADURA

**Introduction.** Important hormonal changes happen during the menopause. These hormonal alterations could be responsible for the increased morbidity that characterizes this period of life (Santoro et al. 1996). The physical activity could have an important regulating effect on female hormonal metabolism during the menopause (Stoddard et al, 2007) **Methods.** Twenty sedentary postmenopausal women (age  $52.27 \pm 3.80$  years) participated in this study. Each participant completed a 6 months supervised exercise training program (60-70% of the maximal heart rate, 60 min/day, 3 days/week) based on aerobic dance. Anthropometric tests and assessment of VO<sub>2</sub>max were carried out and urine samples were taken before and after the exercise program. The following hormones and metabolites were measured by gas chromatography/mass spectrometry: Testosterone, estradiol, estrone, estriol, progesterone, pregnanediol and pregnanetriol. **Results.** Postmenopausal women improved their VO<sub>2</sub>max and also they increased significantly their urinary excretion of progesterone metabolites (pregnanediol and pregnanetriol) after aerobic exercise training. However, urinary levels of estrone, estradiol, progesterone, testosterone and estriol did not change significantly. **Discussion.** The adrenal gland is converted into an important source of progesterone production in postmenopausal women (Sablík et al. 2008), so the increase in urinary excretion of pregnanediol and pregnanetriol would indicate an activation of the suprarenal gland produced by the exercise program. In addition, it may be that there is an adaptive effect of exercise on pregnanetriol and pregnanediol changes and that moderate physical activity does not act on these metabolites in the same way as estrogens. This increase in progesterone would have a beneficial effect on the health of postmenopausal women. **References.** Sablik Z, Samborska-Sablík A, Goch JH. ## PP-PM33 Thermoregulation

**STUDIES OF PHYSIOLOGICAL RESPONSES OF THERMOREGULATORY, HORMONAL, AND IMMUNE IN TRACK AND FIELD AND SWIMMING ATHLETES WITH SPINAL CORD INJURY IN HOT AND COLD ENVIRONMENTS**

SUGAWARA, M.1, TAIMURA, A.2

NAGASAKI UNIVERSITY, FACULTY OF EDUCATION<sup>1</sup>, FACULTY OF ENVIRONMENTAL STUDIES<sup>2</sup>

[Introduction] The purpose of this study was to clarify the influences of exercise-related stress on thermoregulatory, hormonal, and immune responses in hot/cold environments in track and field and swimming athletes with spinal cord injury. The subjects consisted of 5 male wheelchair long-distance athletes with spinal cord injury (wheelchair long-distance athlete group: WLG), 5 male wheelchair-using swimming athletes with spinal cord injury (wheelchair-using swimming athlete group: WSG), 5 healthy male college long-distance athletes (school long-distance athlete group: SLG), and 5 healthy male college swimming athletes (school swimming athlete group: SSG). Informed consent was obtained from all subjects. [Method] The measurement periods were August to March 2009/2010. Exercise was performed in a climatic chamber at a temperature of 28°C with 60% RH while hot (42°C) or cold (15°C) water was circulated through a control tubing suit. The measurement items were thermoregulatory parameters (such as the perspiration rate, esophageal temperature, mean skin temperature, and osmotic pressure), a hormone (catecholamine), and an immunological parameter (reactive oxygen production by neutrophils). [Result] After exercise in hot environment (summer), no differences were observed in the thermoregulatory or hormonal responses among WLG, WSG, SLG and SSG. However, immune responses tended to increase more in WLG than in SLG. No difference was observed among the 4 groups in cold environment (winter). After exercise at 15 (cold water) or 42°C (warm water) using the control tubing suit, no differences were observed in thermoregulatory, hormonal, or immune responses among the 4 groups. Using warm water, thermoregulatory responses tended to be poorer in WLG and WSG than in SLG and SSG. Immune responses did not differ among the 4 groups. [Conclusion] These results suggest a risk of heat disorder due to impaired perspiration on exercise at a high temperature in wheelchair athletes with spinal cord injury. Preventive measures such as the use of a cooling jacket are required. In addition, it is important to clarify the degree of perspiration impairment in wheelchair athletes with spinal cord injury.

**INFLUENCE OF EXPOSURE TO COLD TEMPERATURE ON STRESS-INDUCED SALIVARY BIOMARKERS AND MUCOSAL IMMUNITY**

KAWADA, S., KINUGASA, R., MORITA, N., TAKIZAWA, K., YAMAGUCHI, T., TAKADA, S., YAMAUCHI, J.

THE UNIVERSITY OF TOKYO, FIFSS

Background: Exposure to cold temperature increases psychological stress. Psychological stress activates the hypothalamic-pituitary-adrenal (HPA) axis and the sympathoadrenal medullary (SAM) system (1). Under such conditions, immune function is impaired. It has been shown that salivary IgA levels, an index of mucosal immunity are lower in the first 4 months in Antarctic expeditioners (2). However, it remains unclear whether these changes occur immediately after exposure to cold temperature. The purpose of this study was to investigate whether exposure to cold temperature affects salivary biomarkers of the HPA axis, SAM system, and mucosal immunity in a short period. Methods: Ten healthy males and 2 females ( $25.2 \pm 6.3$  years) performed the following 2 experimental trials at least 1 month apart: (i) sat in a cold chamber ( $-15^{\circ}\text{C}$ ) for 30 minutes [cold trial (CT)]; and (ii) sat in a normal room ( $25^{\circ}\text{C}$ ) for 30 minutes [normal trial (NT)]. Salivary samples were collected pre-trial (baseline) and then at 15-minute (mid-point) and at 30-minute (post-point) cold exposure time points. Salivary cortisol (s-cortisol) as an index of HPA axis, s-amylase activity as an index of SAM system, and s-IgA were evaluated. Results: The levels of s-amylase activity in the CT showed a significant increase at mid- ( $P < 0.05$ ) and post-point ( $P < 0.01$ ) compared to baseline, whereas no significant changes were observed in the NT. For s-amylase activity, condition  $\times$  time interactions were observed ( $P = 0.01$ ). The levels of cortisol in the CT showed a significant increase at post-point ( $P < 0.05$ ) compared to baseline, whereas no significant changes were observed in the NT. For s-cortisol, condition  $\times$  time interactions were  $P = 0.11$ . The levels of s-IgA in the CT showed a tendency to decrease at mid- ( $-8.7\%$ ) and post-point ( $-27.8\%$ ) compared to baseline, but the changes were not significant, whereas in the NT, the levels were almost the same throughout the trial. Conclusion: These results suggest that both HPA axis and SAM system are activated immediately after exposure to cold temperature, whereas suppression of mucosal immunity does not occur in a short period. Grants: This study was supported partly by the Grant for The Polar Research Phase VIII Project in National Institute of Polar Research and Joint Research Program of the Institute of Low Temperature Science, Hokkaido University. **HYDRATION STATE EVALUATION BEFORE AND AFTER A HALF-MARATHON**

LUCIANO SALES PRADO, EMERSON RODRIGUES PEREIRA, CAROLINA FRANCO WILKE, GUILHERME PASSOS RAMOS, ANDRÉ MAIA LIMA, RAUNO ÁLVARO DE PAULA SIMOLA, EMERSON SILAMI-GARCIA

FEDERAL UNIVERSITY OF MINAS GERAIS

Introduction: The hydration status of an individual is known to directly influence performance during prolonged activities in warm environments, but the methods for its evaluations are contradictory. Methods: Aim of the present study was to determine the hydration status and ingested fluid volume of 14 amateur road runners ( $29 \pm 4$  y.o.,  $54.3 \pm 5.5$  mL.kg<sup>-1</sup>.min<sup>-1</sup>) before and after an official running road race of 21.1 km. Mean environmental data along the race were  $25.07 \pm 2.13^{\circ}\text{C}$  dry temperature and  $54.7 \pm 2.2\%$  relative air humidity. Ingested water volume was controlled using marked plastic bottles provided at the hydration stations located at 0, 2.5, 5.0, 7.5, 10.5, 14.0, 16.0 e 18.5 km from the start line. Hydration status was assessed using urine specific gravity (Usg), urine osmolality (Uosm), urine sodium and potassium concentrations ([Na+]<sub>u</sub>, [K+]<sub>u</sub>), plasma volume variation ( $\Delta$ plasma), plasma osmolality (Posm), and plasma sodium ([Na+]<sub>p</sub>) and potassium ([K+]<sub>p</sub>) concentrations. Furthermore, body mass variation ( $\Delta$ BM) was assessed by comparing body mass immediately prior and after the race. Results: Subjects consumed  $0.82 \pm 0.40$  L ( $0.45 \pm 23$  L.h<sup>-1</sup>) of water and sweat  $2.67 \pm 0.23$  ( $24 \pm 3.04$  mL.min<sup>-1</sup>) during exercise. Posm and [Na+]<sub>p</sub> increased after the race, accompanied by a decrease on plasma volume and BM, indicating a state of hypohydration after the race. However, in urine, only [Na+]<sub>u</sub> increased, while all other variables remained unaltered. No significant correlations were observed between Posm and  $\Delta$ BM, and between Uosm and Usg. Conclusion: Posm and  $\Delta$ BM appeared to be the most appropriated variables for detecting acute changes on hydration status at the conditions of the present study. References:

### **A COMPARISON OF THE FLUID BALANCE OF UNIVERSITY AND NATIONAL LEVEL FEMALE BASKETBALL PLAYERS BEFORE AND DURING GAME PLAY**

BRANDENBURG, J.

UNIVERSITY OF THE FRASER VALLEY

A comparison of the fluid balance of university and national level female basketball players before and during game play. Brandenburg, J.P., Gaetz, M. University of the Fraser Valley, Abbotsford, BC, Canada Introduction Proper fluid balance is important for athletic performance. Although elite athletes differ from non-elite athletes in a number of psychological, physical, and physiological qualities, it is unknown if these groups differ with respect to fluid balance. The objective of this study was to compare the fluid balance of university (non-elite) and national (elite) level female basketball players before and during game play. Methods Players of a national team (NT) (n: 11; age:  $24 \pm 3$  y; height:  $180.5 \pm 6$  cm; mass:  $78.6 \pm 8$  kg) and university team (UT) (n: 11; age:  $20 \pm 1$  y; height:  $175.5 \pm 8$  cm; mass:  $74.2 \pm 15$  kg) were assessed while competing in preseason games. Sixty - 45min before game time, players emptied their bladder and specific gravity (USG) was measured. Afterward players were weighed wearing a dry t-shirt and shorts. At completion of the game players towed off and were reweighed in the same attire. Throughout the warm-up and game players had access to fluid in individually labeled bottles. Players ingested fluids ad libitum and were not instructed to consume fluids. Fluid intake was determined by the difference in bottle mass prior to and at the end of the game. The duration (playing time) of both games was 40 minutes. Gym temperature and humidity at game time were  $24.5^{\circ}\text{C}$  and 67% for the NT game and  $24^{\circ}\text{C}$  and 63% for the UT game. Data are presented as mean  $\pm$  SD. Results The USG value for the NT players ( $1.004 \pm 0.002$ ) was significantly less ( $p < 0.001$ ) than that of the UT ( $1.017 \pm 0.007$ ). All NT players arrived with a USG  $< 0.010$  whereas only 3 UT players did the same ( $\chi^2=12.5$ ,  $p=0.002$ ). During game play NT players lost  $0.6 \pm 0.6$  kg, equivalent to a  $0.7 \pm 0.8\%$  loss in body mass and UT players lost  $0.25 \pm 0.5$  kg corresponding to a  $0.3 \pm 0.8\%$  loss in mass ( $p=0.2$ ). Sweat losses, for the combined duration of the warm-up and game, equaled  $2.0 \pm 0.8$  L and  $1.4 \pm 0.5$  L for the NT and UT players, respectively ( $p=0.041$ ). Fluid intake during the game for NT players equaled  $1.6 \pm 0.7$  L or 84% of sweat lost while UT players replaced  $1.3 \pm 0.7$  L of fluid or 99% of sweat lost ( $p=0.4$ ). Discussion All members of the NT were well hydrated before game time. In contrast, only 3 members of the UT were so with the remaining 8 players hypohydrated (4 minimally; 4 significantly). Consequently, once games begin UT players are more prone to becoming hypohydrated to levels that impair playing ability and health. Despite differences in sweat losses, players from both teams consumed fluid at volumes sufficient to keep in-game fluid losses to levels below which decreases in basketball playing ability occur. Regular fluid access and modest environmental conditions may have accounted for this. Strategies to improve pregame hydration should be a priority for university players.

### **CARBOHYDRATE INGESTION DURING EXERCISE IN THE HEAT DOES NOT INFLUENCE NEUROMUSCULAR RESPONSE FOLLOWING PROLONGED AND SUSTAINED SUB-MAXIMAL ISOMETRIC EXERCISE.**

MARINO, F.E.1, NASSIF, C.1,2, GOMES, A.R.3, SOARES, D.D.3, CANNON, J.1, SILAMI-GARCIA, E.3

(1)CHARLES STURT UNIVERSITY, AUSTRALIA; (2)WAIKATO INSTITUTE TECHNOLOGY, NEW ZEALAND; (3)FEDERAL UNIVERSITY OF MINAS GERAIS, BRAZIL.

This study examined the effects of either a 6% carbohydrate drink (CHO) and an equivalent 6% CHO mixture ingested as capsules with distilled water versus corresponding placebo (PLA) treatments and a water (W) hydration treatment on neuromuscular parameters following a 60 km self-paced time trial in the heat ( $32^{\circ}\text{C}$  and 50% rh). Ten well-trained male subjects (mean  $\pm$  SD; age =  $26 \pm 3$  yr; mass =  $64.5 \pm 7.7$  kg; maximum oxygen uptake =  $70.7 \pm 8.8$  mL/kg/min; peak power output =  $323 \pm 41$  W) completed 5 x 60 km cycling time trials in a randomised double-blind fashion. The subjects ingested either PLA capsules or beverage in two trials and corresponding CHO in two trials and W in one trial whilst being informed that both drinks and capsules were CHO in all trials, except the W trial. Neuromuscular assessment which included maximum voluntary contraction (MVC), voluntary activation (VA), evoked twitch contractile properties (ECP) and compound action potentials (M-wave) were conducted pre and post 60 km and then immediately following a sustained isometric contraction at 20% MVC. There were no differences in time to complete the 60 km amongst treatments (range 130.2 - 143.1 min). Core temperature at the end of the trial was not different amongst treatments ( $\sim 38.1 \pm 0.5$  deg.C). A comparable reduction in MVC was observed post - exercise across all treatments (-13%,  $P < 0.05$ ). Voluntary activation was reduced post - exercise in the W treatment only (-2.1%). M-waves remained unchanged post exercise across treatments. ECP post - exercise were significantly altered across all treatments displaying both potentiation and fatigue related effects. The MVC, VA, and M-wave amplitude remained unchanged following the sustained submaximal isometric contraction across treatments. However, ECP demonstrated a significant reduction in the rate of relaxation (pre =  $155 \pm 40.2$  vs post =  $127.6 \pm 36.9$  Nm/s,  $P < 0.05$ ) and an increase in contraction duration (pre =  $173.9 \pm 18.1$  vs post =  $203.1 \pm 20.2$  ms,  $P < 0.05$ ) across all treatments. The present data suggest that the development of neuromuscular fatigue following self-paced cycling in the heat and as assessed by sustained sub-maximal contraction is possibly related to peripheral factors and it appears that carbohydrate ingestion during prolonged exercise in either beverage or capsule form may not provide a protective effect on the development of fatigue following such exercise.

### **ARTERIAL BLOOD PRESSURE RESPONSE TO SEVERE PASSIVE HEATING AT REST RELATES TO HYPERTHERMIA-INDUCED HYPERVENTILATION IN HUMANS**

FUJII, N., ICHINOSE, M., HONDA, Y., TSUJI, B., WATANABE, K., KONDO, N., NISHIYASU, T.

JSPS FELLOW (FUJII, N.), MEIJI UNIVERSITY (ICHINOSE, M.), UNIVERSITY OF TSUKUBA (HONDA, Y., TSUJI, B., WATANABE, K., NISHIYASU, T.), KOBE UNIVERSITY (KONDO, N.)

Introduction When subjected to passive heating at rest, individuals may exhibit an increase, a decrease or no change in mean arterial blood pressure (MAP). Passive heating at rest is also known to increase ventilation, but the magnitude of that response also varies greatly among individuals (Fujii et al. 2008). We tested the hypothesis that the arterial blood pressure response to passive heating at rest is associated with hyperthermia-induced hyperventilation in humans. Methods Eighteen healthy males were subjected to passive heating using legs-only hot water immersion and a water-perfused suit until the subject could no longer endure the heat. We then divided the subjects into two groups: in MAPNOTINC (n = 8) MAP did not increase by  $>3$  mmHg ( $-11.5$  to  $2.3$  mmHg), and in MAPINC (n = 10) MAP

increased by  $>3$  mmHg (9.7 to 32 mmHg). Results Heating-induced increases in esophageal temperature were similar in MAPNOTINC and MAPINC ( $+2.3 \pm 0.3$  vs.  $+2.4 \pm 0.4$  °C). However, subjects in MAPNOTINC showed significantly greater increases in minute ventilation (VE) ( $+19.1 \pm 7.8$  vs.  $+7.1 \pm 4.7$  l min<sup>-1</sup>,  $P < 0.05$ ) and greater decreases in end-tidal CO<sub>2</sub> pressure ( $-15.6 \pm 4.3$  vs.  $-5.1 \pm 4.3$  mmHg,  $P < 0.05$ ) than those in MAPINC. Among all subjects, heating-induced changes in VE significantly and negatively correlated with heating-induced changes in MAP ( $r = -0.74$ ,  $P < 0.05$ ). Discussion Although prolonged voluntary hypocapnic hyperventilation does not lower MAP when sympathetic nerve activity is intact, it does lower MAP through hypocapnia-induced vasodilation when sympathetic nerve activity is attenuated or absent (Onrot et al. 1991). Importantly, hyperthermia attenuates sympathetic vasoconstrictor responsiveness to  $\alpha$ -adrenergic agents in resting humans (Cui et al. 2002). We suggest differences in the degree of hypocapnia induced by hyperthermia-induced hyperventilation may have contributed to the variation in MAP seen with passive heating in the present study. In sum, our results suggest the extent of the MAP response to passive heating at rest is associated with the degree of hyperthermia-induced hyperventilation. ### SWEAT ELECTROLYTES CONCENTRATION AFTER 10KM RUN ON ADMINISTRATION NSAID IN ATHLETES

MARTINS, J., PEZZI, F., DA SILVA, E.R.

FACULDADE SOGIPA

Sweat electrolytes concentration after 10km-run on administration NSAID in athletes Bijoldo, J.M.1, Pezzi ,F.2, da Silva, E.R.3 1: Faculdade Sogipa (Porto Alegre, Brazil), 2:ESEF/UFRGS (Porto Alegre, Brazil), 3: LMH/UCS (Caxias do Sul, Brazil) Introduction The NSAID appears to influence the glomerular filtration rate and consequently the body fluid metabolism may alter the volume and electrolyte composition of sweat. The purpose of this study was to compare sweat rate and electrolytes concentration in runners after two simulated 10km runs under administration of NSAID Ibuprofen (IG) or Placebo (PG). Methods Sixteen athletes (30.7 $\pm$ 5.4 years, 63.9 $\pm$ 6.7 kg, 4.5 $\pm$ 1.2%, 172.6 $\pm$ 7.9 cm, 63.2 $\pm$ 5.4ml.kg.min<sup>-1</sup>) participated of the study. There was no case of self-reported recent use of substances that could impair the renal function Furthermore there was no reported case of kidney failure, hepatic problems or recently perceived or diagnosed Ibuprofen hypersensitivity among the participants, this being one of the inclusion criteria of the sample. The subjects performed two simulated 10km runs on an official athletics track (SC1 and SC2) in two distinct situations: under administration of NSAID Ibuprofen or Placebo (SC1bu and SC1pa respectively). The SC2 seven days after SC1 in order to allow the athletes to recover and to avoid the drug carry-over effect. Pharmacological treatment in SCs consisted in previous (1h) administration of a single dose capsule with 1.2g of Ibuprofen or placebo (lactose) and one member of the research team was especially assigned for drug randomization and administration (double blind). Before each SCs, absorptive patches (3M TEGADERM+PAD 3582) were attached on the skin to collect sweat (scapula), and body mass was measured (scale G-TECH, model BALGLA3C, resolution 0.05kg), with the athletes wearing only shorts after empty their bladders. After SCs, the patches were removed and the athletes emptied their bladders to measure body mass again, with them wearing only shorts and their bodies dry. [Na<sup>+</sup>], [Cl<sup>-</sup>] and [K<sup>+</sup>] in sweat were analyzed in duplicates (electrolyte analyzer, AVL 9180, Roche). Independent t-test was employed to compare groups as data were analyzed using the SPSS 13.0. Results For IG and PG, sweat volume corrected by body surface area (1.3 • 0.4 and 1.1 • 0.3 l.h<sup>-1</sup>) were not significantly different ( $p=0.123$ ). Sweat [Na<sup>+</sup>], [Cl<sup>-</sup>] and [K<sup>+</sup>] was similar between groups ([Na<sup>+</sup>]= 75 $\pm$ 25 and 72 $\pm$ 18 mmol.l<sup>-1</sup>; [Cl<sup>-</sup>]= 68 $\pm$ 14 and 65 $\pm$ 16 mmol.l<sup>-1</sup>; [K<sup>+</sup>]= 8 $\pm$ 2 and 9 $\pm$ 3 mmol.l<sup>-1</sup>, respectively). Discussion In this study there was no change in the volume nor the concentration of electrolytes in sweat possibly due to the low volume of the 10km race. Perhaps a longer race, where the metabolic requirement was greater, or administration of the drug in higher doses could influence the reabsorption capacity of sweat gland, reflecting on the concentration and volume of sweat.

### PP-PM34 Social Aspects of Health and Physical Activity

#### SOCIAL ASPECTS OF SPORTS PRACTISING IN INTEGRATED SETTINGS

DJOBOVA, S., NIKOLOVA, M., GESHEV, P.

NATIONAL SPORTS ACADEMY

Introduction Being aware of the many challenges to promote true social inclusion through sports, the National Sports Academy have begun to consider alternative ways to bring youth with and without disabilities together for practicing sports. One such sport program is NSA Adapted Water Sports Camp. The camp is designed to use sports as a vehicle for improving not only campers' sports skills, but also their self-esteem, and confidence in building relationships with peers. We achieve this by carefully structuring all of our activities to ensure success. Participants are youth with disabilities (ID, CP, ASD). Teaching is done by skilled instructors who break tasks down into manageable chunks and present them in a logical sequence. In this way we can be sure that our campers will be successful. We acknowledge every accomplishment, and never miss the opportunity to provide positive feedback and recognition. The majority of the activities are designed as "Unified sports". The general aim of this study was to estimate the impact of this camp. Methods This study employed a qualitative design combining semi-structured interviews and thematic analysis to evaluate different components such as the development of: self-confidence and self-esteem; sport skills; social and adaptive skills; and development of relationships between the campers with disabilities and the students. The primary sources of data were interviews and field notes. The theoretical model is based on social impact assessment (SIA) methodology (Coreen M. at all). Data: 25 interviews with disabled campers, 42 reports from students, 12 parents' opinions, 7 reports from sports instructors, 5 interviews with supporting staff members. Results The integrated water sports camp appears to be a relatively simple idea – bringing together two groups of young people around a common interest in playing sport. Results showed that according to the parents these camps improved the existing sports skills of campers while also introducing campers to new sports. They report for improved self-confidence. Further, we found that campers with disabilities showed remarkable development in their social and adaptive skills while inclusion in social activities with the students wasn't satisfactory. Discussion According to the examined components the NSA camp has greater impact on the development of the participants with ID in both physical and cognitive aspects. Further work on prejudice and stigmatization is needed in order to achieve greater inclusion which in turn will impact the inclusion in the local communities. References 1. Coreen M. Harada, Gary N. ## EFFICACY OF THE FAMILY INITIATIVE SUPPORTING CHILDREN'S HEALTH PILOT PROGRAMME IN THE NORTH EAST OF ENGLAND

DODD-REYNOLDS, C., ALLIN, L., ALLEN, D.

*NORTHUMBRIA UNIVERSITY*

EFFICACY OF THE FAMILY INITIATIVE SUPPORTING CHILDREN'S HEALTH (FISCH) PILOT PROGRAMME IN THE NORTH EAST OF ENGLAND Dodd-Reynolds, C.1, Allin, L.1, Allen, D.2 1:Northumbria University (Newcastle upon Tyne, England), 2:County Durham and Darlington Community Health Services (County Durham, England) Introduction The Family Initiative Supporting Children's Health (FISCH) obesity project was developed in 2005 by the Durham & Chester-le-Street Lifestyle Initiative. It aims to prevent young people requiring further specialist obesity care through provision of a 10 week health and physical activity intervention over one school term. This pilot study examined the physiological and psychological impact of extending the programme over two terms (20 weeks). Methods A mixed methods design was used. Five schools (3 FISCH (n=91, 9.7±0.5y) and 2 control (n=44, 9.8±0.5y)) in County Durham and Derwentside took part. The programme was delivered by trained FISCH staff and teachers over 20 weeks and included weekly healthy-lifestyle sessions and extra-curricular physical activity. BMI, waist circumference, aerobic fitness and self-perception (Harter, 1985; Hill, unpublished) were assessed at baseline, 10 and 20 weeks; focus groups were conducted at 20 weeks to gauge children's experiences of the programme, health behaviour intentions and family involvement. Results No differences in BMI were seen between FISCH and control or over time. Waist circumference increased slightly in the FISCH group from 0-20 weeks (59.5±7.6 v 60.6±7.9 cm, p<0.01). Step test recovery heart rate was lower for both FISCH and control at 20 weeks compared to 0 and 10 weeks (p<0.05). Self-perception was not altered over 20 weeks, although a positive shift in global self-worth and perception of physical appearance was seen for one FISCH school between 0-10 weeks (p<0.05). Findings from focus groups identified changes to perceptions, attitudes and behaviours following FISCH, notably in doing a greater variety of activities, or trying to eat more healthily and experiencing greater physical fitness and mental wellbeing. They enjoyed the programme and indicated it reinforced and built on their existing knowledge of health. Some children talked about FISCH to parents or siblings at home, but whilst some children experienced support, there was also evidence of challenges and barriers to the changing of existing family lifestyles. Discussion The FISCH 20 week pilot showed positive impact overall, but no change in anthropometric and fitness variables over this duration. We recommend continuation of the FISCH programme, but with extended follow-up and a larger cohort, along with enhanced family involvement and support to maximise efficacy. References Harter S. (1985). Manual for the self-perception profile for children. University of Denver.

## EXAMINING THE FOOTBALL FOUNDATION'S EXTRA TIME PROGRAMME: HEALTHFUL CHANGE IN OLDER PEOPLE

TROTTER, L., RICHARDSON, D., PARNELL, D.

*THE FOOTBALL FOUNDATION*

EXAMINING THE FOOTBALL FOUNDATION'S EXTRA TIME PROGRAMME: HEALTHFUL CHANGE IN OLDER PEOPLE Trotter, L.1, Richardson, D. and Parnell, D.2. 1The Football Foundation (Registered Charity 1079309), Whittington House, 19-30 Alfred Place, London, WC1E 7EA. 2 The Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, UK. Introduction There is evidence of poor physical and emotional health alongside high levels of social exclusion in older people (over 55 years) in England (DOH, 2004). Extra Time (ET) aimed to promote positive healthful changes in older people and was delivered by Football in the Community (FitC) schemes, typically the charitable arms of Football Clubs (FC) in England. This research examines the effectiveness of ET in promoting healthful change in older people. Methods 422 participants, 90% over 60 years old (41% male, 59% female) from 14 of the 20 FitC schemes involved in ET completed entrance and exit surveys (after approximately 8 months engagement within ET between Sept 2009 – Jan 2011). The researchers utilised the principles of ethnography during a period of prolonged fieldwork and extensive observations (typically 1 day per week) in 6 of the 20 FitC schemes. Informal interaction and conversations were collated alongside the researchers' personal reflections. This included additional (but limited to one FitC scheme) baseline measurements of stature and body mass (n=10), which was followed up on a 6 weekly basis with participants. Results Pre-to-post programme survey results showed that 70% of participants reported being able to complete daily tasks easier with 56% reporting that they felt stronger. 84% reported having more support to call upon, with 89% feeling 'like they had someone looking out for them'. Participants reported greater feelings of happiness and confidence. 81% stated the involvement of the FC made ET 'more appealing'. The involvement of the club also offered a greater potential for engagement. Further results from the extensive contextual data indicated positive healthful changes in self confidence and lifestyle (e.g., smoking cessation, reduced alcohol intake). Moreover, within one FitC scheme, weight loss was measured and evidenced, alongside participants' stating that the intimate and bespoke support was critical to their sustained engagement. Discussion Both the national and bespoke research data showed positive (physical and emotional) healthful changes. The sense of support via ET staff and fellow participants suggests that ET is building social support and engagement. In this sense, it would appear that ET enables 'real' healthful changes to occur. ## CREATIVITY AND THE INFLUENCE OF THE PARTNER WHEN DANCING CONTACT IMPROVISATION: A MIXED METHODS APPROACH

TORRENTS, C.1, CASTAÑER, M.1, CAMERINO, O.1, ANGUERA, M.T.2

*1INEFC-UDL (LLEIDA-SPAIN) 2UB (BARCELONA-SPAIN)*

Introduction Contact improvisation (CI) is a form of dance based on motor creativity, improvisation and the physical contact between different improvisers dancing together. This generates different ways of moving and a varied use of motor creativity depending on the dancers involved (Torrents et al. 2010). The aim of this study was to detect differences in movement generation and creativity, depending on the partner, by means of an observational analysis combined with the subjective perception of the dancers. Methods Three contact improvisers were video-recorded while dancing in 5 min solos and duets in a space of 10 m x 10 m. A mixed methods approach (Creswell & Plano-Clark 2007) was used to analyse the data. Trials were sequentially observed by three dance experts using the observational instrument OSMOS (Castañer et al. 2009), with the movements of each dancer being analysed separately. The data obtained were then analysed with Theme Coder software. In addition, after observing the videos of their own dances, dancers responded individually to an oral interview about their motor creativity depending on the partner. The interviews were subjected to a content analysis using Nvivo-v8 Software. Results The observational results showed that motor creativity is affected by the partner, and that it is enhanced when dancing in duets (13 repeated T-patterns were obtained from the 3 solos trials, while just 5 were obtained from the 6 duets trials). The interview

data revealed that dancers identify their own style with the most repeated actions. Some of these actions coincided with observational results, such as the use of a spiralling movement by Participant 1 (75 times), the jumps by Participant 2 (45 times) and the locomotion combined with turns by Participant 3 (45 times). Dancers also considered that their style was especially modified due to the influence of the partner, and they agree that this helped them to be more creative. While they identified some original movements in their dance, they also believed that this form of dance is always original because of its improvisational nature. Discussion The sequential mixed methods approach used in this study shows that dancing with a partner enhances motor creativity. The influence of the partner is confirmed by both the quantitative results obtained through the observation of the movements performed and the qualitative approach based on the subjective comments of the dancers. ## THE CORRELATION BETWEEN SELF-PERCEIVED HEALTH STATUS AND PHYSICAL FITNESS, IN SEPTUAGENARIAN AND OCTOGENARIAN

BEZERRA, P., ALVES, D.

IPVC (PORTUGAL); CIDESD (PORTUGAL)

Introduction The health-related quality of life may be assessed by SF-36v2 questionnaire. This questionnaire is comprised of eight measures including physical functioning (PF) and role physical (RP), and combines two scales – physical (PH) and mental health. Handgrip (HT) and 6 minutes walking (6MW) tests may assess physical fitness. Whether or not changes in self-perceived health status are related with physical fitness in septuagenarian (70') and octogenarian's (80') is not clear. The aim of this study was to examine the relationship between the subject's perception of health and the physical fitness, in 70' and 80'. Methods Fifty-five 70' (75.2±3.0 yrs, 67.8±10.8 Kg, 1.53±0.11 m) and twenty-three 80' (84.9±3.5 yrs, 66.0±10.3 Kg, 1.52±0.11 m) volunteers were recruited from local population with fifty-three being women and twenty-five being men. The participants completed the SF-36v2 questionnaire, and were tested on HT of the right and left hand, and 6MW. T-Test was used to compare 70' and 80' on HT, 6MW and SF36v2 parameters. Pearson coefficient of correlation was used to assess the relationship between SF-36v2 results on PF, RP subscales and PH scale, and physical fitness tests. Results Significant differences were found between 70' and 80' in PF (61.55±24.87; 47.61±23.45,  $p < 0.05$ ), RP (52.65±26.15; 38.83±29.36,  $p < 0.05$ ) and PH scale (55.27±19.12; 46.04±15.23,  $p < 0.05$ ). In relation to physical fitness, significant differences were found between 70' and 80' in both hands (left – 22.42±9.99 Kg, 15.26±9.96 Kg; Right – 22.98±10.75 Kg, 17.61±10.31 Kg,  $p < 0.05$ ) and cardiorespiratory capacity (6MW) (364.44±99.36 m, 269.30±88.73 m,  $p < 0.001$ ). Moderate correlations were found between RP, PF and PH scale and HT ( $r = 0.37$  to  $0.46$ ,  $p < 0.001$ ), in 70'. In 80', moderate correlations were found between both PF and PH scale and 6MW ( $r = 0.44$  to  $0.58$ ,  $p < 0.001$ ). Discussion Results showed that 70' were stronger, had better cardiorespiratory capacity, and responded more positively than 80' when assessing self-perceived physical health scale. However, the muscle strength was found to be correlated with RP, PF and PH scale but not with cardiorespiratory capacity, in 70'. On the other hand, cardiorespiratory capacity was found to be correlated with PF and PH scale, in 80'. It appears that the muscle strength contributes significantly to the self-perception on physical health scale in 70' while a good cardiorespiratory capacity promotes self-perception on physical health in 80'.

## REACTION TIME OF CHILDREN WITH AND WITHOUT AUTISTIC SPECTRUM DISORDERS

BAISCH, B., CAI, S., LI, Z.M.

UNIVERSITY OF AKRON, CLEVELAND CLINIC FOUNDATION

Autism has long been associated with movement abnormalities, although the neurobehavioural details of these abnormalities remain poorly defined. The purpose of this study was to compare simple and choice reaction times in students with and without autism. Methods A total of 34 children participated in the study. The group with autism consisted of 17 males and 7 females between the ages of seven and thirteen. The control group consisted of a total of 10 typically developing students. A laptop installed with a reaction time test software known as LabView was used for the tests. Results The means and standard deviations were calculated for comparison and the data were evaluated from the results of a t-test. Significant differences were found among all reaction time tasks ( $p < .001$ ), whereas the group consisting of children with autism demonstrated slower reaction times and greater standard deviations compared to the typically developing/ control group. Discussion The slower reaction time from the group with autism may have been directly related to deficits in the perceptual motor process. The differences in mean reaction times among all tasks ranged from about 350 msec to 387 msec, implying deficiencies at both the response and perceptual levels. The choice reaction time tasks did require motor reprogramming, but due to the similar ranges in mean reaction time differences between the two groups among all tasks, the results did not coincide with the results of Rinehart and associates' study (2001). The prevalence of motor impairments may have also been a factor in why the group with autism demonstrated significantly slower reaction times than the typically developing group. In a retrospective clinical record review by Ming, Brimacombe, and Wagner (2007), results suggested that fine motor control and programming deficits are common co-occurrence of children with ASD in this cohort. The reduced prevalence of motor deficits in older children suggest improvement over time, whether through natural progression, results of interventional therapy, or the combination of the two (Ming, Brimacombe, & Wagner, 2007). Therefore, younger children, such as the adolescents in this study, may not have received the services to improve their fine motor skills, which may be contributing factors in this study's tasks. References Ming, X., Brimacombe, M., & Wagner, G. C. (2007). Prevalence of motor impairment in autism spectrum disorders. Brain and Development, 29(9), 565-570. Rinehart, N. J., Bradshaw, J. L., Brereton, A. V., & Tonge, B. J. (2001). Movement preparation in high-functioning autism and Asperger disorder: A serial choice reaction time task involving motor reprogramming. ## PROVIDING A REFERENCE POINT – PRACTITIONER REFLECTIONS FROM A COMMUNITY BASED FAMILY INTERVENTION DELIVERED WITHIN A PROFESSIONAL FOOTBALL CLUB

PARNELL, D., WATSON, L., NEWLAND, A., BINGHAM, D., RICHARDSON, D.

LIVERPOOL JOHN MOORES UNIVERSITY

Introduction: There is currently a paucity of research into the working practices of employees within Football in the Community (FitC) schemes (Watson, 2000). The Everton Active Family Centre is based at Goodison Park, and the result of a unique collaboration between Liverpool John Moores University (LJMU) and 'Everton in the Community' (Everton Football Club's official charity). The research offers an insight into complex and holistic nature of the work undertaken at the centre, and provides a reference point as to the characteristics that

combine to produce an effective support practitioner within such an environment. Methods: A total of 7 families were utilised in the research over a period of 7 months. The research objectives were facilitated through ethnographic principles. Methods of data collection included field notes, informal interviewing and discussion and more formal semi-structured interviews. Through a series of reflections, the practitioner aims to facilitate the readers understanding of the broad range of challenges they are faced with on a day to day basis, and the skill base required to meet these demands. Results: Interview data illustrated the flexible nature of the practitioner and the differing role it was playing within the family's lives (i.e., personal trainer, lifestyle coach, counsellor). A number of families identified the centre as simply a vehicle upon which to achieve their health targets. Conversely, for others the centre was playing a much more fundamental role, in allowing participants to gain more control of their lives. Reflections throughout the research illuminate the broad skill base the practitioner draws upon and the flexible nature of their role, when required to deal with more fundamental life issues such as mental illness, chronic disease and disability. Discussion: The research indicated that practitioners working in such health related football community programmes were exposed to an eclectic array of potential clients. Whilst each practitioner was experienced in a main area of expertise (e.g., fitness, health and/or social-psychological backgrounds) it is important to note that they each, in-turn, offered the client(s) a 'reference point' for the resolution of a number of health and lifestyle issues. In this regard, the practitioners must possess an adaptable, flexible and holistic approach to their work in order to deal with the diverse range of issues that the client brings in to this environment. ## PROMOTING HEALTH IN HARD TO REACH AND DEPRIVED POPULATION THROUGH ENGAGING LOCAL COMMUNITIES

MINOU, M.

LIVERPOOL JOHN MOORES UNIVERSITY

Promoting health in hard to reach and deprived population through engaging local communities Minou, M.1, Murphy, R.1, Stratton, G.1 1: Research Institute for Sport and Exercise Sciences, Liverpool John Moores University. UK. Introduction People from ethnic backgrounds have low levels of physical activity (PA) (HSE, 2008). Influencing (PA) behaviours and identifying its determinants requires understanding and approaching it from a broader socio-ecological perspective (Sallis and Owen, 1999). Determining barriers to participation and promoting PA in BRM populations is inherent with difficulty (Yancey et al., 2004). This research aimed to develop a process by which BRM groups can be reached in the planning and evaluation phases of PA programme development and implementation. Method Two advisory groups, (Partners Advisory and a Community Research Advisory groups) that included representatives from local communities, leisure, recreation and educational organisations were set up to develop a research and delivery partnership. An action research approach was put into practice with a customised survey designed collectively by the advisory groups. The socio-ecological model (Sallis and Owen, 1999) was used to explore women's PA determinants. Survey findings informed the agenda of focus groups in order to explore key issues raised in the survey. Results Two hundred and thirteen women from 16 ethnic backgrounds completed the survey, whereas 17 women participated in follow up focus groups. Over half of the women consulted were not involved in PA. Findings indicated that PA in BRM women was influenced by intrapersonal, interpersonal, social and physical environmental factors. These included lack of motivation, time, access to information and facilities and the ability to speak English. Discussion This research demonstrated the significance of cultural and community partnership in advocating and empowering communities to collect robust evidence for health promotion and the development of needs-based over product-led based services. The interventions should provide a framework of support in relation to service provision ranging from making sure that women are aware of events and activities taking place through to providing appropriate resources and venues in order to get women to a place where they can start to lead more physically active lifestyles. ## HEALTH PROMOTION INTERVENTIONS AMONG DISADVANTAGED COMMUNITIES

MINOU, M.

LIVERPOOL JOHN MOORES UNIVERSITY

Health promotion interventions among disadvantaged communities Minou, M.1, Stratton, G.1, Murphy, R. 1 1: Research Institute for Sport and Exercise Sciences, Liverpool John Moores University. UK. Introduction Effective physical activity (PA) intervention on a public health level requires an inclusive concept that integrates various delivery approaches that meet specific needs of the target diverse subpopulations (Yancey et al., 2004). The "Work- Out" project involved practitioners (fitness activators) from the local communities and was designed to meet the specific needs and interests of inactive deprived communities through increased participation in PA (Bauman et al., 2002). Methods A bespoke survey was designed to measure the PA levels, maintenance of the behaviour change and service satisfaction. One hundred and fifty three participants completed the survey. Individual interviews guided by the socio-ecological model (Sallis and Owen, 1999) were conducted with participants, practitioners and managers (n=16) to identify the influence of the fitness activators and other social and environmental factors in promoting PA. The RE-AIM framework (Glasgow et al., 1999) was then applied to assess the effectiveness of the intervention in more detail. Results The survey revealed an 85% increase in PA levels. The project reached 1200 individuals from disadvantaged areas and 90% of participants were satisfied with the service. The intervention effectively increased people's engagement in the community and participation in PA. This was through the support system by the fitness activators and the provision of a 12-week free gym pass which removed barriers for participation. Fitness activators adopted a unique marketing strategy to recruit inactive disadvantaged people. The intervention was implemented successfully within the time line and the budget allocated. Participants maintained their activity levels 3 months post intervention. Discussion The multi-component community based intervention effectively promoted participation in PA and promoted social inclusion in a deprived area through providing social support and facilities, and removing barriers such as: cost and lack of access to information and resources. References Bauman, A., Bellew, B., Brown, W., and Owen, N. (2002). Getting Australia active. Towards better practice for the promotion of physical activity. ## BEHAVIOR MODIFICATION PROGRAM FOCUSING PRIMARILY ON NON-EXERCISE ACTIVITY THERMOGENESIS HAVE EFFECT ON SELF-EFFICACY AND THE MODERATE -INTENSITY PHYSICAL ACTIVITY OF UNIVERSITY STUDENTS

YAMAUCHI, T., KITAMURA, K., NAGAYAMA, T., TAKATO, J., KUDO, T., SAKATA, T.

ISHINOMAKI SENSU UNIVERSITY

BEHAVIOR MODIFICATION PROGRAM FOCUSING PRIMARILY ON NON-EXERCISE ACTIVITY THERMOGENESIS HAVE EFFECT ON SELF-EFFICACY AND THE MODERATE -INTENSITY PHYSICAL ACTIVITY OF UNIVERSITY STUDENTS Takeshi Yamauchi 1, Katsuro Kitamura 2, Takahiro Nagayama 2, Jinro Takato 3, Toshimi Kudo 4, Takashi Sakata 1 1: Ishinomaki Senshu University (JPN), 2: Tohoku University (JPN), 3: Tohoku Bunka Gakuen University (JPN), 4: Miyagi Gakuin Women's University (JPN) Introduction One of the important considerations to examine the effectiveness of the non-exercise activity thermogenesis (NEAT) from various angles is thought to be the assessment of self-efficacy, in addition to the amount of physical activity. This intervention study documented the effect of behavior modification program focusing primarily on NEAT on self-efficacy and the amount of physical activity of university students who claimed to be unhealthy. Methods A 10-weeks behavior modification program focusing primarily on NEAT was implemented and the results were analyzed. Fifty participants were randomly assigned to either the intervention group or the control group. Participants in both groups took a 90-min seminar once a month for purposes of understanding health promotion, in particular NEAT. Participants in the intervention group wearing a triaxial physical activity monitor (actimarker EW4800P-K: Panasonic) except the time of bath and sleep underwent an intervention based on the results of physical activity monitor once a week during 10 weeks. Physical activity counts were converted into METs-time and divided into vigorous-intensity physical activity (at least 6 METs), moderate-intensity physical activity (at least 3 and less than 6 METs), and low-intensity physical activity (less than 3METs). A survey method of general self-efficacy was the questionnaire. Results In the intervention group, the results showed an increase in the amount of physical activity among participants who had moderate-intensity physical activity, while an upward trend was observed among the participants with low-intensity physical activity. Additionally, the students in the intervention group experienced a reduction in body weight and an enhancement in general self-efficacy. Summary These results demonstrated the effectiveness of behavior modification program focusing primarily on NEAT among unhealthy students.

## WEIGHT LOSS AND CHANGES IN BODY WEIGHT DUE TO ACTIVE TRAINING PROGRAMS

ROJO, M.A., BENITO, P.J., PEINADO, A.B., CALDERÓN, F.J.

UNIVERSIDAD POLITÉCNICA DE MADRID

WEIGHT LOSS AND CHANGES IN BODY WEIGHT DUE TO ACTIVE TRAINING PROGRAMS Rojo, M. A.1, Benito, P. J.1, Peinado, A. B.1, Calderón, F. J.1 on behalf of the PRONAF Study Group 1: Facultad de Ciencias de la Actividad Física y del Deporte – INEF, Universidad Politécnica de Madrid (Spain). Introduction The world is facing major problems associated with the rapid increase in levels of overweight and obesity, such as chronic diseases and higher rates of disability (1, 2). Some studies (3-5) have analyzed the problem showing that diet is a prerequisite for weight loss. The aim of the present study was to analyze what was the influence of some factors in the body weight loss and generate an equation to predict it. Methods 87 overweight people (BMI: 25-29,9 kg•m<sup>-2</sup>), aged 18-50 years, participated in the study (36 men, 51 women). They were randomly assigned to four intervention groups: resistance training (RT, n=22), endurance training (ET, n=25), combined training (CT, n=23) and control group (C, n=19). All of them in combination with diet restriction during 6 months of intervention. The Pearson Product Moment Correlations were used to assess the relationships between weight loss and different descriptive variables. Step by step regression analysis was used to estimate the weight loss. Determination coefficient (R<sup>2</sup>) and standard error of estimation (SEE) was used to show the accuracy of estimation. Probability level for statistical significance was set at p=0.05. Results We obtained the following correlation coefficients for weight loss and body weight, sex, age, BMI and efficacy BMI 25 Index: r=0,222 (p=0,038), r=0,256 (p=0,016), r=0,184 (p=0,087), r=0,222 (p=0,038) and r=0,569 (p<0,001), respectively. With the regression analysis it was obtained the following predictive weight loss models: Weight loss (kg) = -8,507+0,524\*(BMI)+1,721\*(Sex, men=1, women=0) (R<sup>2</sup>=0,093; SEE=3.8 kg) Weight loss (kg) = -115,4+2,481\*(BMI)+0,541\*(Efficacy BMI 25 Index) (R<sup>2</sup>=0,768; SEE=1,92 kg) Discussion Hagan (6) showed that the weight loss is different according to sex. Other studies (4, 7, 8) have shown differences between the type of intervention realized. Del Corral (4) found that adherence to diet is a strong predictor of weight loss during a wide range of dietary restriction, so this variable should be included in the new prediction models. We conclude that the weight loss is related to the variables BMI and sex. References 1. Macfarlane DJ. British Journal of Sports Medicine. 2010;44(16):1197-201. 2. Worthy SL, et al. ## ANTHROPOMETRIC CHARACTERISTICS OF CLUB AND VARSITY LEVEL GAELIC GAMES PLAYERS AS DETERMINED BY DUAL X-RAY ABSORPTIOMETRY

DORAN, D.1, MC GEEVER, S.1, COLLINS, K.2

1. LIVERPOOL JOHN MOORES UNIVERSITY, UK. 2. INSTITUTE OF TECHNOLOGY TALLAGHT, DUBLIN, IRELAND.

Introduction Assessment of body composition is a central component of performance profiling in Gaelic games. In research and applied settings estimated body fat percentage (BF %) is estimated from skinfold thicknesses (Reilly and Collins, 2008). Gaelic games literature reports wide variances in these estimates despite players being drawn from notionally similar populations. The variances may be due to technical errors in data collection and/or violation of generic assumptions regarding bone and tissue density. Dual X-ray absorptiometry (DXA) represents a methodology which may eliminate issues associated with skinfold based estimates of body composition. The aims of the present study were to establish reference values of body composition in Gaelic games players using DXA and to compare between the codes of Gaelic Football (GF) and Hurling (HRL). Methods Forty-three players; 20 GF and 23 HRL (age 21 ± 1.7 yrs vs 21 ± 2.1 yrs) respectively underwent whole body fan beam measurement by DXA (Hologic QDR, Delphi Series A, USA). Scans were analysed using standardised protocols with the Hologic QDR analysis software version 12.4. Measurement occurred at the midpoint of the competitive season, with all players engaged in training and competition. Derived variables included body mass (BM), fat mass (FM), lean mass (LM), body fat

percentage and bone mineral content (BMC). Results No significant differences in height ( $179.6 \pm 5.7$  cm vs  $180.2 \pm 7.1$  cm) and body mass ( $76.8 \pm 7.8$  kg vs  $81.6 \pm 9.0$  kg) were evident between the codes. BF% ( $16.2 \pm 4.7\%$  vs  $18.7 \pm 4.7\%$ ) did not differ between GF vs HRL ( $P > 0.05$ ). Fat mass was significantly lower in the GF vs HRL ( $11.5 \pm 3.7$  kg vs  $14.6 \pm 4.5$  kg) ( $P < 0.05$ ). No differences in LM ( $58.5 \pm 5.4$  kg vs  $60.0 \pm 7.1$  kg) ( $P > 0.05$ ) or BMC ( $2.5 \pm 0.3$  kg vs  $2.6 \pm 0.3$  kg) ( $P > 0.05$ ) between GF and HRL were apparent. Discussion Gaelic games players present a relatively homogenous anthropometric profile. The hurlers tended to be slightly taller and heavier with higher adiposity and lean muscle tissue mass than the GF although this was significant for FM only. BF% are at the higher end of previously reported values for these populations, reflecting the performance heterogeneity of the players, differing work rate and intensity profile of GF vs HRL codes and potential underestimation of adiposity attributable to skinfold methods. The current DXA BF% values represent the first reported DXA based norms for Gaelic games as such this will provide a data set to which field methods may be compared. Further extension of this data set to elite gaelic games populations is warranted. References, Reilly T, Collins, K. (2008). Eur J Sport Sci, 1, 84–94.

### **MORPHOLOGICAL CHARACTERISTICS AND SITUATIONAL EFFICIENCY OF K-1 SUPER HEAVYWEIGHT FIGHTERS AT THE K-1 GP FINAL TOURNAMENT 2010**

KAPO, S., RADJO, I., HARINCK, T., CIKATIC, B., TORLAKOVIC, A., HASANOVIC, E.

*FACULTY OF SPORTS AND PHYSICAL EDUCATION, UNIVERSITY OF SARAJEVO*

**Introduction** What this article aims to do is to identify K-1 fighters' situational efficiency parameters by registering the use of a group of tactical and technical elements applied by the winners and defeated fighters in the Final K-1 Grand Prix Tournament in Japan in 2010. **Methods** The sample consisted of eight top-level K-1 super heavyweight fighter specialised in different contact sports (boxing, kick boxing, karate, muay thai, etc.) fighting according to K-1 rules. Data were collected on the basis of video recordings of seven fights, based on which the K-1 tournament analysis was performed. The collected data were processed using descriptive statistics. Variables were processed using the formula for the technical and tactical elements application efficiency in K-1 fights  $K-1 = x / Ny \times 100 \%$ . **Results and discussion** The basic descriptive parameters of morphological characteristics of all fighters indicate that the average height is 191.5 cm, ranging from 182 to 212 cm. The average weight is 109.5 kg, ranging from 90 to 133 kg. From the analysis of the punches and kicks frequency we can conclude that the total frequency of punches is 1294 or 67.4%, and kicks 625 or 32.6% of the total number of received blows at the tournament. The most frequent punches were direct punches 783 or 40.80%, whereas the most frequent kicks were low kicks 330 or 17.30%. Hand techniques are more dominant than leg techniques most likely due to their energetic efficiency since they require less energy. From we can gather that the most dominant defence techniques are pulling away 343 or 24%, hand blocks against punches 338 or 23.7%, evasion 331 or 23.2%. Further on, we have hand blocks against kicks 182 or 12.8%, leg blocks against kicks 178 or 12.5% of the total number of blocks applied during the tournament. This coincides with the analysis of punches and kicks frequency. Suggests that the most dominantly used tactical means is combined tactics (6 or 42.9%), followed by offensive tactics 5 or 35.7% and defensive tactics 3 or 21.4%. We can see that the victory was most frequently achieved by decision 4 or 57.1 %, by knock-out 2 or 28.6%, and by forfeit due to injury 1 or 14.2 % . **Conclusion** The analysis of the K-1 GP Final Tournament in Japan in 2010 points out the statistical dominance of the hand boxing technique over the leg techniques since the former require less energy, they are also much faster, simpler, and have a larger impact on the course of the fight The larger frequency of circular kicks and knee blows characteristics of Muay Thai, kick boxing and MMA suggest that boxing, Muay Tahi, kick boxing and MMA are fundamentally important for fighting successfully in K-1. **References** Kapo, S. ### **ANTHROPOMETRIC CHARACTERISTICS OF ELITE KENYAN MARATHON RUNNERS**

VERNILLO, G., BERARDELLI, C., AGNELLO, L., MAGGIONI, M.A., LA TORRE, A.

*FACULTY OF EXERCISE SCIENCES, UNIVERSITÀ DEGLI STUDI DI MILANO*

**Introduction** Despite over the last ten years several studies attempted to explain the success of Kenyan marathon runners proposing explanations included environmental-, psychological-, and physiological-factors, little is known about the anthropometric characteristics of them. Consequently, the aims of this study were to describe the current anthropometric profiles of elite Kenyan marathon runners and establish a set of reference values useful for future investigations on athlete selection, talent identification, and training programme development. **Methods** In a cross-sectional design, 14 male Kenyan runners were assessed for the measurement of skinfolds, segment lengths, breadths, and girths according to previous works (Carter and Heath, 1990; Norton and Olds, 2004; Stuelcken et al., 2007). All variables except body mass and height were measured on the right side of the body in triplicate with the median value used as the criterion. To estimate body density (BD) multiple regression equations were calculated using the sum of 3-skinfolds method (Jackson and Pollock, 1978) and then converted to percentage of body fat (% BF) (Siri, 1961). The somatotype, somatotype dispersion mean (SDM), somatotype attitudinal mean (SAM), and height to weight ratio (HWR) were calculated using the method and equations of Carter and Heath (1990). **Results** The mean (s) of age, height, weight and marathon personal best were 27.7 (3.7) yrs, 171.2 (6.1) cm, 57.7 (4.0) kg, and 02h 07min 16s (01min 55s). The mean (s) of BD, % BF, SDM, SAM, and HWR were 1.13 (0.02), 8.8 (0.07) %, 4.6 (3.6), 0.5 (0.1), and 44.3 (1.0), respectively. The mean (s) endomorphy, mesomorphy, and ectomorphy were 1.5 (0.3), 1.6 (1.8), and 3.8 (0.7), respectively. **Discussion** The mean somatotype of Kenyan marathon runners evaluated could be defined as ectomorph, having ectomorphy as dominant, and endomorphy and mesomorphy more than one-half unit lower. Despite population comparisons would be required to identify any connection between specific anthropometric dimensions, these reference data should be useful to practitioners and researchers, providing useful information for talent identification and for the assessment of training progression in marathon. **References** Carter JEL, Heath BH. ### **PROPOSITION OF EQUATIONS FOR PREDICTING BODY FAT VALUES IN PROFESSIONAL SOCCER PLAYERS**

OSIECKI, R.I, NOVACK, L.F.I, OSIECKI, A.C.V.I, ANANIAS, G., DOURADO, A.C.2

*1: UNIVERSIDADE FEDERAL DO PARANÁ (CURITIBA- BRAZIL), 2: UNIVERSIDADE ESTADUAL DE LONDRINA*

**Introduction** An accurate estimation of body composition in athletes, especially soccer players, provides an important component in a training program, in the control of body weight and the maintenance of a high level of physiological functioning. However, there is a

noticeable lack of specific predictive equations for soccer athletes. Therefore, the aim of this study was to propose mathematical equations for elite soccer athletes, using anthropometric measures for predicting body fat and DXA as a reference method. Methods This study involved 31 male professional footballers who participated in the Professional League of Brazil, with mean values of age of  $21.48 \pm 3.38$  years, body mass  $79.05 \pm 9.49$  kg, height  $181.97 \pm 8.11$  and body fat  $13.68 \pm 4.22\%$ . The athletes underwent an analysis of anthropometric measurements of weight, height, body circumferences, bone width, and skinfolds and as a reference for comparison, we used the Dual-energy X-ray Absorptiometry - DXA. To obtain the equations for estimating body fat we used the multiple regression technique. Results Several equations were proposed from the analysis performed in this study, but the equations that showed the best results for the adjusted coefficient of determination ( $R^2a$ ) and standard error of estimate (SEE) of body fat percentage, were as follows:  $\%BF = 0.83196071$  (midaxillary) +  $0.16367624$  (abdominal) +  $0.75492553$  (thigh) -  $2.33295828$  ( $R^2a = 0.839$ , SEE = 1.690)  $\%BF = 0.67901792$  (midaxillary + thigh) +  $0.07619429$  (abdominal + midaxillary) +  $0.06801188$  (chest + abdominal + midaxillary + thigh) -  $2.37873851$  ( $R^2a = 0.840$ , SEE = 1.689)  $\%BF = 0.75055662$  (midaxillary + thigh) +  $0.13910823$  (abdominal + midaxillary) -  $2.46345040$  ( $R^2a = 0.845$ , SEE = 1.662)  $\%BF = 0.67901792$  (midaxillary + thigh) +  $0.14420618$  (abdominal + midaxillary) +  $0.06801188$  (thigh + chest) -  $2.37873850$  ( $R^2a = 0.849$ , SEE = 1.689) Discussion Considering also other statistical indicators, the mathematical models proposed in this research showed determination coefficients higher than the ones reported by Reilly et al (2009)  $R^2 = 0.78$  in a study involving footballers and Eston et al (2005),  $R^2 = 0.79$  and  $0.67$ , proposed for non-athlete individuals. The adjusted coefficient of determination ( $R^2a$ ), presented by Reilly et al (2009) in their study with the goal of proposing an equation to predict body fat for soccer players, was lower ( $R^2a = 0.73$ ) than the values found in our results. ## MORPHOLOGICAL CHARACTERISTICS AND MOTOR ABILITIES OF THE YOUNG BALLET DANCERS

SUZOVIC, D., PORCIC, B.

FACULTY OF SPORT AND PHYSICAL EDUCATION

MORPHOLOGICAL CHARACTERISTICS AND MOTOR ABILITIES OF THE YOUNG BALLET DANCERS Suzovic, D.1; Porcic, B.2 1 Faculty of Sport and Physical Education, Belgrade, 2 Ballet School "Lujo Davico", Belgrade Introduction Little data are available on growth and development of young classical ballet dancers. The objective of this study was to determine how growth and development processes determine the morphological and motor abilities of young female dancers. The growth and maturation showed influence in morpho-functional abilities at young female dancers (Steinberg, N. et al. 2008). Methods Eighty-four girl students of the Primary Ballet School of 12,84 ( $\pm 1,14$ ) years of age (mean (SD)), and the body height 157,0 ( $\pm 9,0$ ) cm and body mass 43,1 ( $\pm 7, 6$ ) kg. were divided into 4 sub-samples according to the school grade (n = 26 (1st grade); 16 (2nd); 24 (3rd) and 18 (4th), respectively, aged 11,58  $\pm 0,58$  (1st grade), 12,68 $\pm 0,59$  (2nd), 13,33 $\pm 0,57$  (3rd) and 14,13 $\pm 0,68$  (4th). Their BMI was derived from their body height and body mass. The data regarding the motor abilities were obtained by applying the standard EUROFIT test battery which determines the order of implementation of individual tests, recommended for standardized use in the countries of the European Council (Kukulj et al. 1993). It was hypothesized that the maturation have influence on morphological and also on motoric abilities at young dancers. The results were analyzed using descriptive (mean and SD) and comparative (1-way ANOVA) statistical procedures. Results and discussion The obtained findings support the hypothesized effect of maturation. Specifically, the results revealed the differences in morphological characteristics, but not in body composition. The youngest girls were the lightest and with the lowest body mass. They also revealed significantly lower BMI, when compared with the students of the third and fourth grade. The evaluated motor abilities suggested the differences among the groups in the Plate Taping, Standing Abroad and the Agility test 10x5m, where generally the oldest girls revealed better scores than the youngest. Conclusion We can generally conclude that the development at the studied age is not characterized with changes in body composition, while the specific ballet and gymnastic practices could improve motor abilities to reach the necessary requirements for ballet performance. From the practical aspect, however, the obtained findings suggest that the applied EUROFIT battery of motor ability tests could be used as one of the criteria for early selection at classical ballet school (Wyon et al. 2004 ). Acknowledgments The study was supported in part by a grant from Serbian Research Council (#145082). References Kukulj, M. et al. (1993): *Fizicka kultura*, 47, 4: 196-200, Steinberg, N. et al. ## FUNCTIONAL AND BODY COMPOSITION CHARACTERISTICS OF TOP CZECH FEMALE SOCCERS

BUNC, V., HRASKY, P., BALAS, J.

FACULTY OF P.E. AND SPORTS CHARLES UNIVERSITY

FUNCTIONAL AND BODY COMPOSITION CHARACTERISTICS OF TOP CZECH FEMALE SOCCERS Bunc,V. Hráský, P., Baláš, J. Faculty of P.E and Sports Charles University, Prague, Czech Republic Introduction The laboratory testing - evaluation of changes in morphological, cardiorespiratory and metabolic variables during exercise, may help to explain the process of adaptation to the training stimulus, and these variables could be used for training checking. The most frequently used variables for the characterisation of training state are related to the VT. Another variable which may be used for indirect evaluation of changes in adaptation to exercise is the energy cost of exercise. Methods Nowadays could be used together with long time used classical parameters of body composition – body fat content and free fat mass - also other variables which may characterise the BC like are body cell mass (BCM) and extracellular mass (ECM). The fact that differences in body size and BC influence the predisposition and interpretation of parameters such as absolute and relative  $VO_{2max}$  and/or physical performance is well known. Less well studied are the effects of differences of BC on functional variables in top female soccer players. The physiological profiles of 27 top Czech female players (national team members) (mean age =  $23.0 \pm 3.4$  years, mass =  $78.9 \pm 6.3$  kg, height =  $182.4 \pm 5.4$  cm,  $\%BF = 10.8 \pm 2.1\%$  and  $ECM/BCM = 0.78 \pm 0.06$ ) were measured on the treadmill with 5% inclination. Results Mean  $VO_{2max.kg^{-1}}$  was  $54.6 \pm 3.5$  ml.kg<sup>-1</sup>.min<sup>-1</sup>. Mean value of maximal running speed was  $15.6 \pm 1.0$  km.h<sup>-1</sup>, and  $LAm_{ax}$  was  $11.2 \pm 1.3$  mmol.L<sup>-1</sup>. The selected variables at the VT level corresponded to  $VO_{2.kg^{-1}} = 43.6 \pm 1.4$  ml.kg<sup>-1</sup>.min<sup>-1</sup>,  $\%VO_{2max.kg^{-1}}$  at VT level were  $79.8 \pm 1.5\%$ , speed =  $13.0 \pm 0.4$  km.h<sup>-1</sup>,  $\%v_{max}$  at VT level were  $83.3 \pm 1.4\%$ . The energy cost of running was  $3.85 \pm 0.22$  J.kg<sup>-1</sup>.m<sup>-1</sup>. Discussion The actual motor performance and thus the actual training state is partly a consequence of their genetic predisposition and partly a consequence of the moving training they undertake. In practice it is difficult to separate these two components. As in other sports events where the skills play the decisive role, the physiological data are not the sole predictor of racing success. It is necessary remark that these standards are necessary but not only sufficient conditions for success in the race, but the decisive predispositions for long lasting successful training process. These data play important role in selection of talents for particular sports event. Conclusion We may conclude that the physiological characteristics of top female players should be as follows:  $ECM/BCM < 0.75$ ,  $VO_{2max.kg^{-1}} > 56$  ml.kg<sup>-1</sup>.min<sup>-1</sup> in defenders, and  $> 60$  ml.kg<sup>-1</sup>.min<sup>-1</sup>, in midfielders and forwards. Maximal speed (at 5% inclination) should be  $> 16$  km.h<sup>-1</sup> in all

players, the speed at VT > 13.0 km.h<sup>-1</sup>, %VO<sub>2</sub>max at VT level > 81.0%, and the energy cost of running < 3.83 J.kg<sup>-1</sup>.m<sup>-1</sup>. The study was supported by grant of Czech Ministry of Education MSM 115100001.

## BIOCHEMICAL AND BODY COMPOSITION EFFECTS OF ULTRA RUNNING

KARSTOFT, K., SOLOMON, T.P.J., LAYE, M.J., PEDERSEN, B.K.

RIGSHOSPITALET, FACULTY OF HEALTH SCIENCES, UNIVERSITY OF COPENHAGEN,

**Introduction** An increasing number of subjects are participating in various ultra races. Although ultra races are considered to be harmful to health, evidence is sparse regarding the harmful or beneficial effects of ultra races on a whole body composition or biochemical level. **Methods** 8 experienced long distance runners (7 male, 1 female; age 44±2, BMI 23.5±0.5, number of marathons finished 108±27) participating in the Danish ultra race event "7 marathons in 6 days" (1), underwent biochemical screening (blood sampling) and body composition assessments (dual-energy X-ray absorptiometry) before and after the race. Data are presented as Mean±SEM. **Results** Overall finish time for the 7 marathons was 28.3±1.4 h (range 23.4 – 34.4 h) with the last 3 marathons significantly faster than the first two marathons (p<0.05). The average fastest single marathon finish time occurred at day 7 (3:50±0:11:28, range 3:14:44 – 4:42:58 h) and slowest was day 2 (4:10:24±0:14:11, range 3:27:08 – 5:21:28). A substantial decrease in fat mass (12.0±2.3 vs. 10.4±1.9 kg, p<0.05) was seen with a corresponding increase in lean body mass (62.8±2.9 vs. 64.7±3.0 kg, p<0.05) leading to no weight change overall. Biochemical screening showed minor muscle cell damage after the race (Creatine Kinase: 198.9±48.4 vs. 639.9±99.4 U/l, p<0.05) and a corresponding small increase in inflammatory markers such as C-reactive protein (1.0±0 vs. 6.0±1.1 mg/l, p<0.05). Alanine (ALT) and aspartate (AST) transaminases, traditionally seen as evidence of liver cell damage also showed a minor increase (ALT: 26.8±3.6 vs. 38.8±5.3 U/l, p<0.05. AST: 29.1±2.8 vs. 56.6±7.1 U/l, p<0.05), whereas no changes were seen in liver function markers. No haemolysis was seen. Fasting insulin levels dropped (49.3±7.8 vs. 22.5±2.7 pmol/l, p<0.05) with no changes in fasting glucose. An improved cholesterol profile with decreased total cholesterol (4.9±0.3 vs. 4.4±0.2 mmol/l, p<0.05) and increased high-density lipoprotein cholesterol (1.7±0.2 vs. 2.0±0.1 mmol/l, p<0.05) was found. **Discussion** In this small sample of highly trained subjects, no major adverse effects were seen after running 7 marathons in 6 days. On the other hand, markers of metabolic health were significantly improved following the race. **In conclusion**, it was shown that daily marathon running for 6 days did not elicit a large physical damage measured by a broad range of biochemical variables, and that certain health related parameters, such as fat mass, total cholesterol and HDL, improved substantially following the event. **References** 1: <http://www.tejnlif-lob.dk/www/index.php/62448timer/resultaterultrammarathonforside/res2010ultrammarathon>

## ANTHROPOMETRIC PROFILE OF ELITE MALE ICE CLIMBERS AND ITS INFLUENCE ON COMPETITION RANK

VUJIC, S.1, MIRKOV, D.2, DIKIC, N.1, KUPPER, T.3, TOTIC, S.4, DJOKOVIC, A.4, RADIVOJEVIC, N.1, ANDJELKOVIC, M.1, OBLAKOVIC, B.J.1, BARALIC, I.5

1:SMAS,BELGRADE;2:FACULTY OF SPORT AND PHYSICAL EDUCATION,BELGRADE;3:AACHEN TECHNICAL UNIVERSITY,GERMANY;4:FACULTY OF ORGANIZATIONAL SCIENCES, BELGRADE;5:FACULTY OF PHARMACY,BELGRADE

**Introduction:** Although, Ice climbing World Cup is organized in the last ten years and some National Championships even longer, anthropometric profile of ice climbers remained unknown. The aim of this study was to determine anthropometric profile of elite ice climbers (IC) and its influence on competition rank. **Methods:** The 23 male (age 26.7±5.9) participants of the Ice climbing World Cup were measured day before competition. Control group (age 23.8±2.6) was made of 23 non climbers (NC), students from Faculty of sport. The variables measured included age, height, weight, body mass index, % body fat by bioimpedance, % segmental body fat (trunk, left and right arms, -legs), fat mass, leg length, arm span, ratio of arm span to height (Ape index), right and left handgrip strength, handgrip strength to body mass ratio (SMR), pincer strength (dominant hand, i.e. thumb and forefinger), handgrip endurance (dominant hand), endurance of shoulder's muscles, foot raise, hip flexion, hip abduction and climbing ability trough standing position (Grant S., 1996; Mermier CM., 2000; Watt PB., 2003; Giles LV., 2006). **Results:** Elite ice climbers compared with NC have less height, weight, % body fat, BMI, BMR, FFM and TBW (p<0.05). They have the same arm span and leg length but higher Ape index. Tests of strength, endurance and flexibility are the same, except that Ice climbers have significant better hip abduction (p<0.05). Age, handgrip endurance, SMR, foot raise and hip abduction had significant influence on competition rank in Ice climbing (p<0.05) while handgrip strength (left and right) shown significance of (p<0.01). **Discussion:** Elite ice climbers have moderate body composition with low fat % and good hip flexibility. This anthropometric profile of elite ice climbers have shown that except endurance, strength and flexibility, success on competition is influenced by experience which coming with age, as well as with improvement of climbing techniques. **References:** Grant S., Hynes V., Whittaker A., Aitchison T. ## THE WAIST MEASURE POINT AFFECTS THE DIAGNOSIS OF CENTRAL OBESITY

RODRIGUEZ, D.

SÃO JUDAS TADEU UNIVERSITY

THE WAIST MEASURE POINT AFFECTS THE DIAGNOSIS OF CENTRAL OBESITY Rodriguez, D.2,3, Silva, V.1, Guiselini, M.2, Pontes Jr, F.L.3 1: FEFISO/YMCA (Sorocaba, Brazil), 2: IREP (Sao Paulo, Brazil), 3: USJT (Sao Paulo, Brazil), 4: USP (Sao Paulo, Brazil) **Introduction** According to the systematic review by Ross et al. (2008) the midpoint and umbilical point are the most used to measure the waist circumference. Taking this in consideration, the aim of this study was to analyze how the waist measurement point affects the diagnosis of central obesity. **Methods** We evaluated 13,129 persons (7047 women and 6082 men), aged between 10 and 79 years. The indicators of central obesity were considered waist circumference (WC), waist/hip ratio (WHR), conicity index (CI) and waist/height (WHtR). All indicators of central obesity were determined for the midpoint (MID) and umbilical point (UMB). The mean difference (MD) between the MID and the UMB was determined based on algorithmic UMB subtraction (minuend) less than the MID (subtrahend). We used operational definitions proposed for two Brazilians author (Pitanga e Lessa 2004, 2005 e 2006), and we used the tests of two-way ANOVA, post hoc Newman-Keuls, frequency table and chi-square test (P ≤ 0.05). **Results** All indicators of central obesity showed significant differences which affect significantly those results as following; (p <0.01) between the MID and UMB. In WC, MD of 6.16 cm for women and 3.18 cm for men, (p <0.01) the prevalence of central obesity in 17.5% for women and 12.4% for men. In the WHR, MD of 0.063 for women and 0.031 for men, (p<0.01) the prevalence of central obesity in 28.2% for women and 16.6% for men. In CI, MD of 0.093 for women and 0.043 for men, (p<0.01) the prevalence of central obesity in 45.8% for women and 20.8% for men. In WHtR, MD of 0.038 for women and 0.018 for men, (p<0.01) the

prevalence of central obesity in 11.5% for women and 10.7% for men. Discussion Studies that determine the morbimortality through anthropometric indicators showed that the WC, WHR, CI and WHtR, explain the morbimortality better than BMI (Pitanga e Lessa 2004, 2005 e 2006). However, the systematic review by Ross et al. (2008), involving 120 studies showed that several points are used to measure the WC. According to the results presented in this study, the point of WC measurement affects significantly the diagnosis of central obesity. Therefore, if the abdominal obesity is defined at the midpoint, for example, no other point must be used for diagnosing abdominal obesity. References Pitanga FJ, Lessa I. #### TRAINING LOAD, STRESS TOLERANCE AND UPPER RESPIRATORY SYMPTOMS IN PROFESSIONAL BASKETBALL PLAYERS

FREITAS, C., SCHULTZ DE ARRUDA, A.F., AOKI, M.S., MOREIRA, A.

UNIVERSITY OF SÃO PAULO

**Introduction** The main goal of sport training process is to maximize athletic performance. In order to achieve this goal, it is imperative to prescribe appropriate training loads to induce positive outcomes, enhancing performance. Therefore, the aim of the present study was to investigate the behavior and relationships among internal training load (ITL), stress tolerance (ST) and upper respiratory symptoms (URS) in professional basketball players during one macrocycle training. **Methods** The sample was composed by 12 professional basketball athletes ( $22 \pm 5$  years,  $94 \pm 22$  kg, and  $196 \pm 10$  cm). The study was conducted for 19 weeks. The macrocycle was separated by three distinct phases (preparatory phase = [P1], and two competitive phases = [P2 and P3]. In order to assess internal training load, the session ratings of perceived exertion (session-RPE, Foster 1998) was utilized for every training session and official match. The Daily Analysis of Life Demands for Athletes' questionnaire (DALDA; sources and symptoms of stress) and the Wisconsin Upper Respiratory Symptom Survey (WURSS-21) were used on a weekly basis to assess ST and URS severity, respectively. **Results** The results from ANOVA with repeated measures showed significant differences among the three phases to all analyzed variables ( $p < 0.05$ ). The ITL showed significant increments from P1 to P2. At P3, the answers "better than normal" (DALDA; for both sources and symptoms) showed a significant decrease. A significant increase to URS severity was noted to P3. In addition, significant relationships were verified between ST and URS at P3 (URS x Sources "worse than normal" = 0,69 and URS x Symptoms "worse than normal" = 0,60). The answers "better than normal" seems to better explain the changes in ST. **Discussion** The main finding of the present study was the congruence among the psychometric tools, during the main phase of the season (P3), we noted significant increments in URS associated with amplified stress despite of the reduction in ITL. These results suggest that other factors (i.e. emotional and psychological) than ITL alone could induce to increments in the stress levels as well as in URS. Moreover, the answers "better than normal" (DALDA) seem to better explain the changes in ST, indicating the importance to retain this variable to monitoring the stress reaction. In summary an approach incorporating in conjunction these psychometric tools could be an efficient means of monitoring reaction to stress in professional basketball during an entire macrocycle in accordance to a psychophysiological perspective. **References** Foster, C. #### RECOVERY-STRESS STATE AND IMMUNOLOGICAL VARIABLES AFTER DIFFERENT TRAINING PERIODS IN SWIMMERS

SIMOLA, R.A.P.1, FILHO, A.G.2, NEVES, S.R.S.3, RAMOS, M.G.3, SAMULSKI, D.M.1, PRADO, L.S.1

1: FEDERAL UNIVERSITY OF MINAS GERAIS, BRAZIL, 2: FEDERAL UNIVERSITY OF PERNAMBUCO, BRAZIL, 3: FUJMEC, BRAZIL

**Introduction:** Immunological and psychological variables are commonly used as an index of training stress (Gleeson, 2002), even though significant differences between immunological variables after different training phases may not be observed (Coutts et al. 2007). We investigated the effects of different training loads on recovery-stress state (RSS) and immunological variables. **Methods:** Subjects were highly trained, male swimmers ( $17.7 \pm 1.3$  y.o.). RSS and immunological variables (monocytes, lymphocytes, eosinophils and total leukocytes) were evaluated after two distinct training phases. During the first phase (T1), subjects swam approximately 50.000 meters/week during 01 week. During the subsequent phase (T2) (04 weeks), swimmers covered an average of 45.000 meters/week at a considerably higher intensity. RSS was evaluated using the RESTQ-Sport questionnaire for the Portuguese language (Costa & Samulski, 2005). The Student's t-test and Pearson's correlation coefficient were used for parametric variables. The Wilcoxon test and Spearman correlation coefficient were used for non-parametric variables. Significance level was  $p < 0.05$ . **Results:** Lymphocyte levels increased significantly from T1 to T2 ( $2005,6/\mu\text{l} + 321,78$  vs  $2230,0/\mu\text{l} + 472,51$ ). No significant changes were observed in RSS. After T1, positive correlations between monocytes and "social relaxation" and a significant negative correlation between lymphocytes and "social stress", "conflicts/pressure" and "self-efficacy" were observed ( $p < 0.05$ ). After T2, positive correlations between leucocytes and "being in shape" and between lymphocytes and "emotional exhaustion" were noted ( $p < 0.05$ ). **Conclusion:** Neither the immunological variables, except lymphocyte levels, nor psychological aspects were sensitive to the alterations on training routine used in the present study. Correlations between immunological and psychological variables showed no identifiable pattern. Even though the investigated variables may be useful for monitoring training programmes, their behaviour after different training modes deserve further investigation. **References:** Costa, L.O.C.; Samulski, D.M. ### EFFECTS IN LIPID PROFILE OF THREE DIFFERENT EXERCISE PROTOCOLS IN OVERWEIGHT PEOPLE

ROMERO MORALEDA, B., MORENCOS, E., PEINADO, A.B., BUTRAGUEÑO, J., CUPEIRO, R., ROJO, M.A., BENITO, P.J., CALDERON, F.J.

UNIVERSIDAD POLITÉCNICA DE MADRID

**EFFECTS IN LIPID PROFILE OF THREE DIFFERENT EXERCISE PROTOCOLS IN OVERWEIGHT PEOPLE** Romero, B<sup>1</sup>; Morencos, E<sup>1</sup>; Peinado, A. B<sup>1</sup>; Butragueño, J<sup>1</sup>; Cupeiro, R<sup>1</sup>; Rojo, M. A.; Benito, P. J<sup>1</sup>; Calderon, F. J<sup>1</sup> on behalf of the PRONAF Study Group <sup>1</sup> Facultad de Ciencias de la Actividad Física y del Deporte – INEF. Universidad Politécnica de Madrid. (Clinical Trials gov number: NCT01116856) **Introduction** Major risk factors for cardiovascular diseases (CVD) include hypertension, smoking, serum total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), low levels of high-density lipoprotein cholesterol (HDL-C) and triglycerides (TG). Physical inactivity and reduced cardiorespiratory fitness contribute to the risk of CVD, whereas there is consistent, substantial, and strong evidence that physical activity is a deterrent for developing cardiovascular disease [1]. The aim of this study was to know what kind of exercise could be more effective to improve lipid profile in overweight people. **Methods** Ninety participants with overweight (18 – 50 years; BMI > 25 and < 30 kg/m<sup>2</sup>) were randomized to one of the following groups: strength training (ST; n = 22), aerobic training (AT; n = 25), a combination of AT and ST (COM; n = 23), 3 times/wk for 24 wk, and control group (CG; n = 20). All of them in combination with diet restriction. The measurements took place for all subjects before training at weeks 1 to 4, and after 16 weeks of training in weeks 21 to 24. All groups were evaluated for changes in blood concentrations of lipoprotein-lipids, cardiovascular fitness, body composition, and dietary composition. Two way ANOVA with repeated measures was used to determine differences between moments (before and after intervention). The significant level was set at  $\alpha \leq 0.05$ . **Results** Lipid profile showed improvements in all groups. Triglycerides (TG) had a significant decreased in ST (23.53%;  $p < 0.001$ ) and AT (14.29%,  $p < 0.05$ ). AT, COM and CG significantly reduced total cholesterol (TC) 11.4%, 21.75% and 16.88% ( $p < 0.01$ ) respectively. Low-density lipoprotein-cholesterol (LDL-C) was significantly decreased in COM (16.15 %,  $p < 0.001$ ) and CG (14.7 %,  $p < 0.001$ ). **Discussion** The results of the present study are in agreement with recently reported results that showed improvements in lipid profile with aerobic training [2, 3], resistance training [4] and combination [5]. In summary the present study showed that all training methods may improve lipid profile. **References** 1. Blair, S.N., et al. *Med Sci Sports Exerc* (2001); 33:762-64. 2. ### MONOCYTE INTRACELLULAR CYTOKINE PRODUCTION IN ELITE CANOEISTS AND NON-ATHLETES

BORGES, G.1, RAMA, L.1, ROSADO, F.1, ALVES, F.3, SANTOS, A.1, GOMES, B.1, MASSART, A.1, SILVA, A.C.2, PEDREIRO, S.2, PAIVA, A.2, TEIXEIRA, A.M.1

1:RESEARCH CENTRE FOR SPORT AND PHYSICAL ACTIVITY, FCDEF-UC, COIMBRA. 2:HISTOCOMPATIBILITY CENTRE, COIMBRA. 3:FACULTY OF HUMAN KINETICS, TECHNICAL UNIVERSITY OF LISBON, LISBON.

**Introduction** Exercise training or higher levels of physical activity are known to exert anti-inflammatory effects. In responses to exercise the monocytes produce pro-inflammatory cytokines like IL-1 $\beta$ , IL-6 and tumor necrosis factor (TNF). The present study examined the effect of training on monocyte intracellular cytokine production in elite canoeists after an off training period of 6 weeks and in non-athletes. **Methods** The sample was composed by 11 canoeists athletes, with a mean of  $22.0 \pm 4.3$  years old,  $77.2 \pm 6.7$  Kg weight and  $177.5 \pm 5.6$  cm high with an initial  $\dot{V}O_{2\max}$  of  $61.2 \pm 5.5$  ml.Kg.min<sup>-1</sup> and 7 health men, who had no practice of regular exercise, with a mean  $18.5 \pm 1.3$  years old,  $81.3 \pm 10.7$  Kg weight and  $171.9 \pm 4.5$  cm high. Blood samples were collected by venopuncture. In the present study, intracellular cytokines in blood leukocytes were analyzed by flow cytometry. Results are expressed as the percentage and number of cytokine-producing cells in CD33+ populations. The absolute count was determined by multiplying the percentage of cytokine-positive monocytes by the concentration of monocytes in peripheral blood. For quantification of the amount of cytokine within positive cells, the mean fluorescence intensity of positive events was obtained. **Results** There were no significant differences between groups in white blood cells, lymphocyte, monocyte and granulocyte counts ( $p > 0.05$ ). The percentage of monocyte intracellular cytokine expression was higher in athletes for IL-1 $\beta$  ( $p < 0.05$ ) and lower for IL-6 ( $p < 0.05$ ) and TNF- $\alpha$  ( $p < 0.05$ ). **Discussion** Athletes appear to have an attenuated cytokine response. Regular physical training has been demonstrated to attenuate the immune response to exercise in either direction (Gokhale et al., 2007). Pedersen et al. (2004) have concluded that IL-6 has a modulatory effect on TNF- $\alpha$  along with a variety of functions such as: induction of lipolysis, suppression of TNF production and stimulation of cortisol production. The altered relationship between IL-6 and TNF- $\alpha$  and the significant higher values in untrained subjects suggest that a source of IL-6 other than the muscle may be interfering in the network (Smith et al., 2000). Our study observed that same after an off training period of 6 weeks where the monocyte intracellular cytokine expression was different between athletes and non-athletes. **References** Gokhale R, Chandrashekara S and Vasanthakumar KC. (2007). *Cytokine*, 40, 123- 127. Pedersen BK, Steensberg A, Fischer C et al. (2004). *Proc Nutr Soc*, 63, 263–267. Smith LL. (2000). *Med Sci Sports Exerc*, 32(2), 317–31.

### IMPACT OF TWO DIFFERENT RESISTIVE EXERCISE METHODS ON POST-EXERCISE IMMUNE CELLS AND CORTISOL PLASMA LEVELS

RODRIGUEZ, D.

SÃO JUDAS TADEU UNIVERSITY

**IMPACT OF TWO DIFFERENT RESISTIVE EXERCISE METHODS ON POST-EXERCISE IMMUNE CELLS AND CORTISOL PLASMA LEVELS** Rodriguez D.1 Neves R. X.2, Falconi C. A.2, Almeida V.T.2, Siqueira U.2., Charro M. A.2, Pontes Jr F. L.3, Junior A. F.1, 2 1 USJT (São Paulo, Brazil); 2 USCS (São Caetano/SP, Brazil); 3 USP ( São Paulo, Brazil) **Introduction:** Resistive exercise may induce muscle damage and acute inflammatory response (Peake et al. 2005). A single bout of intense resistive exercise may induce transient immunosuppressive effect. However, the manner that the immune system will be challenged depends in great part of the characteristic of the training session (Chen et al. 2009). The aim of this investigation was to determine the effect of two different resistive exercise methods on acute lymphocytes, leukocytes and monocytes and cortisol plasma levels. **Methods:** Young adult men (n= 10;  $26.1 \pm 6.3$  years old;  $174.0 \pm 5.4$  cm-height;  $76.4 \pm 13.3$  kg- weight;  $15.5 \pm 5.4$  % body fat) with no previous experience in resistive exercise were divided into two groups. Both groups performed two different exercise sessions with one week interval between them. The training sessions consisted in three consecutive exercises for the same muscle group (bench press, incline bench press and peck deck) with workload determined by one maximum repetition (1MR) test. The variable intensity group (VIG) performed 3 maximum repetitions (MR) sets for each exercise at 67%, 74% and 80% of 1MR. The constant intensity group (CIG) performed 3 MR sets for each exercise at 75% of 1MR. Blood samples were obtained from an antecubital vein at rest

and immediately after the exercise sessions. The immune cells and cortisol were analyzed by dual-labeled flow cytometry. Student t paired test ( $p < 0.05$ ) was applied to compare pre and post immune cells and cortisol plasma levels. Results: Data evidenced similarity for all plasma analyzed variables pre-post resistive exercise session in CIG. On the other hand VIG presented significant decrease in lymphocytes post-exercise ( $2843 \pm 129^*$ ) compared with pre values ( $3809 \pm 249$ ) ( $*p < 0.05$ ). Cortisol levels also presented increase ( $p < 0.05$ ) after variable intensity session ( $162 \pm 24$  PRE;  $312 \pm 41^*$  POST). Conclusion: Crewther et al. (2008) reported that hormonal responses are proportional to the load lifted however, data allowed us to conclude that the variable intensity session was more stressful to immune system than constant intensity loads. The effect of different intensities (VIG and CIG) did not present the same impact on immune cells and stressor hormones (cortisol). Also we may suggest that if variable intensity method has to be applied it should be performed for shorter periods of time. References Peake J, Nosaka K, Suzuki K. (2005) *Exerc Immunol Rev*; 11:64-85. Chen TC, Chen HL, Lin MJ, Wu CJ, Nosaka K. (2009) *Eur J Appl Physiol*, 106(2):267-75. Crewther B, Cronin J, Keogh J, Cook C. ## EFFECTS OF BILLAT TRAINING ON BLOOD LIPIDS AND IMMUNE SYSTEM IN FEMALE SERBIAN JUDOKAS

TRIVIC, T., DRID, P., OBADOV, S.

FACULTY OF SPORT AND PHYSICAL EDUCATION

**Introduction** Training is one of the methods to improve exercise performance, but too much training and competitions cause adverse effects in biochemical and hematological parameters and affects on health state of athletes. The present study was designed to evaluate the changes in total antioxidant activity, total and differential white cell counts and blood lipids at female Serbian judokas after four week training program, without weight reduction. **Methods** The sample of this research consisted 9 female judokas from Serbia national team, age  $23.11 \pm 3.95$  years, who take a bronze medal on European team championship. Blood samples were collected to measure blood lipids, total and differential white cell counts and total antioxidant activity. Complete blood tests were done on instrument SAFIR firm Abot. Biochemical parameter has been providing on instrument ADVIA 1800 firm Bayer Siemens. Total antioxidant activity in serum were done by FRAP method. **Results** General results of study showed a significant increase in total cholesterol concentrations after second measurement ( $p < 0.001$ ) at female Judokas, significant decrease of HDL-C ( $p < 0.05$ ), and significant increase in nonHDL and LDL-C concentrations ( $p < 0.001$ ). In addition, decrease ( $p < 0.05$ ) were found in eosinophile count and increase in monocytes and basophiles after training program. **Discussion** This study has documented that this training program has no negative effect on total antioxidant activity of athletes without proper nutrition, but on lipid profile indicate otherwise. Therefore, beneficial adaptations in lipoprotein profile must be achieved with moderate training intensities and proper nutrition (Aellen et al., 1993). Lipids have important beneficial biological functions. These include usage of triglycerides for energy production, fat storage in adipose tissues, and usage of cholesterol as a component in phospholipids of cellular membranes or in the synthesis of steroid hormones (Heitkamp et al., 2008; Kelley and Kelley, 2009). Regular monitoring of these health-related variables of female judokas players can provide valuable information about their health, metabolic and cardiovascular status. However, results from our research demand attention in further training program, which may have probably provoked negative effects on the lipid profile in elite Serbian female judokas. **Reference** Aellen R, Hollmann W, Bouteiller I. ## PRE-SEASONAL PREPARATION TRAINING AND IMMUNE RESPONSES IN YOUNG WELL-TRAINED SOCCER PLAYERS

HADJICHARALAMBOUS, M., PARPA, K., GIANNAKI, C., MICHAELIDES, M.

UNIVERSITY OF NICOSIA

**Introduction** It was suggested that athletes involved in long-term high intensity exercise are susceptible to upper respiratory tract infection (Nieman et al., 1990); since various aspects of immune function are temporarily suppressed following strenuous physical activity (Pedersen & Hoffman-Goetz 2000). This response might be a limiting factor in exercise performance (Tuan et al. 2008). However, although this is evident during long-term high-intensity training little is known regarding the immune responses to strenuous soccer-specific pre-seasonal preparation training in young soccer-players. The purpose therefore of the present study was to examine the immune responses to 8-weeks of overload pre-seasonal training in young well-trained soccer players. **Methods** All anthropometric measurements, physical fitness components and immune responses of eighteen ( $n=18$ ) well-trained soccer-players were evaluated in two occasions: a) immediately prior to the initiation of preparation period (pre-conditioning) and b) following the completion of the 8-weeks' training program (post-conditioning). **Results** Pre-seasonal training did not affect absolute white ( $\times 10^3/\text{micl}$ ) and red ( $\times 10^6/\text{micl}$ ) blood cells but it significantly increased relative (%) number of resting circulating blood neutrophils ( $p < 0.005$ ) and decreased blood lymphocytes ( $p > 0.005$ ). Blood monocytes, eosinophils basophils and platelets were not altered ( $p > 0.05$ ). Plasma cortisol was significantly lower at post-conditioning ( $p < 0.05$ ). Body weight, BMI, resting systolic and diastolic blood pressure and sit-and-reach flexibility all were not different between pre- and post- conditioning ( $p > 0.05$ ). HRmax and body fat % were reduced ( $p < 0.05$ ) and aerobic capacity, leg explosiveness, muscular endurance [1 min-sit-ups and 1 min-push-ups] were improved ( $p < 0.05$ ) by the end of preparation period. **Discussion** In conclusion overload pre-seasonal preparation training induced increased mobilization of relative number of neutrophils counts and decreased relative number of lymphocytes counts in young high-level soccer players. This may suggest an immunosuppression and potential susceptibility to infections. These responses may partially be explained by the physiological muscle-damaged responses to strenuous long-term exercise training. It remains however, to be determined potential physiological techniques for counterbalancing these immune responses to long-term strenuous exercise training. **References** Nieman DC, Johanssen LM, Lee JW, Arabatzis K. ## EFFECTS OF STRENGTH TRAINING AND FISH OIL SUPPLEMENTATION ON LYMPHOCYTE ACTIVATION MECHANISMS

GORJAO, R.

CRUZEIRO DO SUL UNIVERSITY

**EFFECTS OF STRENGTH TRAINING AND FISH OIL SUPPLEMENTATION ON LYMPHOCYTE ACTIVATION MECHANISMS** Gorjão R.1, Barquilha G.1, dos Santos A.J.1, Momesso C.1, Curi R.1, Piñon-Curi T.C.1; Hirabara S.M.1 1Post-Graduate Program in Human Movement Sciences, Cruzeiro do Sul University, 2Department of Physiology and Biophysics, University of Sao Paulo, Brazil **INTRODUCTION** High intensity strength exercise may induce muscle damage resulting in an inflammatory response that may modulate lymphocyte activation mechanisms (1). Studies have shown that n-3 fatty acid supplementation reduces inflammatory process in subjects submitted to aerobic exercise (2). The

purpose of this study was to examine the effects of strength exercise training and n-3 fatty acid supplementation on lymphocyte activation mechanisms. **METHODS** Sixteen untrained male subjects (25 ± 5 years of age) participated in this study. The strength training protocol was performed during seven weeks, three times a week. The protocol consisted of alternation between hypertrophy and strength sessions. Eight subjects were supplemented for 2 months with 3 g/day of fish oil (FO) (54% EPA and 23% DHA). Blood was taken from trained subjects before and immediately after the first session of hypertrophy exercise. After 8 weeks of training and supplementation the blood was taken before and immediately after the session of hypertrophy exercise. CD25 expression in CD4+ lymphocytes, DNA fragmentation and membrane integrity were evaluated by flow cytometry; proliferative capacity were determined by incorporation of [2-14C]-thymidine. Akt and ERK1/2 phosphorylation were detected by western-blotting. **RESULTS** The proliferative capacity of lymphocytes decreased after the first hypertrophy session (4362 ± 370 to 2630 ± 304 cpm). After two months of training no difference was observed. The supplementation did not alter proliferation. There were no differences in DNA fragmentation and membrane integrity in any situation. Percentage of CD25 positive cells was decreased after the first hypertrophy session (22 % to 9 % of total lymphocytes) but returned to the initial values after 8 weeks of training. Akt and ERK1/2 (proteins related to lymphocyte proliferation) phosphorylation were decreased after the first hypertrophy session, however, no effect was observed in the end of the training. Likewise, fish oil supplementation had no effect. **DISCUSSION** The present study indicates that there is a reduction in lymphocyte function after a week of high intensity session of hypertrophy exercise in untrained individuals. This is due to an inhibition of intracellular pathways related to proliferation. Fish oil did not alter lymphocyte response. Moreover, the chronic training decreased lymphocyte proliferation without changing signaling pathways. This effect is probably related to an alteration in circulatory cell population leading to a lower lymphocyte self-activation. **REFERENCES** 1.Ramel et al. (2003) J Sports Sci, 21: 1001–1008. 2.Pedersen et al. (2000) Int. J. Sports Med, 21(1), 4–9. Support: Fapesp, Capes and CNPq

### LEUKOCYTE COUNTS ARE INFLUENCED BY MENSTRUAL CYCLE AND CARBOHYDRATE INGESTION IN WOMEN DURING PROLONGED EXERCISE IN A HOT ENVIRONMENT

HASHIMOTO, H., ISHIJIMA, T., SUZUKI, K., HIGUCHI, M.

WASEDA UNIVERSITY

**Introduction** Ingesting carbohydrate drink during prolonged strenuous exercise prevents an increase in circulating leukocyte counts. This evidence suggests that carbohydrate substrate metabolism influences an immune system in such an exercise. We reported in the previous study that a menstrual cycle affects substrate oxidation in which the carbohydrate oxidation in the luteal phase was increased as compared to follicular phase. Based on these results, we hypothesized that menstrual cycle and carbohydrate ingestion affect the circulating leukocyte counts during a prolonged exercise in a hot environment. **Methods** Six healthy women with regular menstrual cycles completed total of four trials which consists of 90 min of cycling exercise at the intensity of their 50% VO<sub>2</sub>peak with the performance test afterwards in a hot environment. Each trial was performed either with the ingestion of carbohydrate drink or the placebo drink pre and during exercise at their follicular phase (FP) and luteal phase (LP), respectively. The data of the concentration of expired gas, heart rate, and rectal temperature were collected during the exercise. Blood samples were taken before and after exercise and every 30 min during exercise. **Results** The results in this study were that 1) menstrual cycle affected the leukocyte counts during prolonged exercise in a hot environment, about 37% higher in LP as contrast with in FP at 90th min of exercise, 2) ingestion of carbohydrate drink during exercise suppressed the acute increase of leukocyte and diminished the difference in increase of leukocyte counts between FP and LP, 3) the effects of menstrual cycle and ingesting carbohydrate drink in the response of leukocyte during prolonged exercise was associated with the substrate metabolism in each trial. **Discussion** It is well known that acute increase of leukocyte during exercise leads to the reduction of leukocyte after exercise as compared to pre exercise, resulted in the decrease in their immune system. Suppression of increase in leukocyte by ingesting carbohydrate might be linked with the attenuation of the susceptibility to a viral infection. Ingesting carbohydrate during prolonged strenuous exercise might be needed in women with regular menstrual cycle, especially in luteal phase, not only for a substrate supplementation but also for a prevention of decrease in their immune system.

### EFFECTS OF CIRCENCIS PHYSICAL EXERCISE ON LYMPHOCYTE ACTIVATION IN OVERWEIGHT AND EUTROPHIC CHILDREN

GORJAO, R.

CRUZEIRO DO SUL UNIVERSITY

**EFFECTS OF CIRCENCIS PHYSICAL EXERCISE ON LYMPHOCYTE ACTIVATION IN OVERWEIGHT AND EUTROPHIC CHILDREN** Momesso CM.1; Takeo F.2; Cassoni C.1; Cury-Boaventura MF.1 Caçula K.1; Guirado S.1; Borges CN.1 Coneglian V.2; Hirabara SM.1 ; Curi R.2; Pithon-Curi TC.1 Gorjão R.1. 1Post-Graduate Program in Human Movement Sciences, Cruzeiro do Sul University, 2Department of Physiology and Biophysics, USP, Brazil **INTRODUCTION** Obesity associated with sedentary lifestyle can lead to changes in the immune system function, resulting in the development of inflammatory diseases. The occurrence of these diseases may be related to a change in the primary control exerted by T lymphocytes on the immune system (1). The aim of this study was to evaluate the mechanisms of lymphocyte activation in overweight children, when performing or not circencis physical exercises. **METHODS** The studied group was composed by 43 children, pubescent, divided in four subgroups: Overweight Children (OWC) (10.67 ± 0.90 years old and BMI 23.02 ± 2.74); Overweight Exercise (OWE) (10.00 ± 1.41 years old and BMI 24.64 ± 3.03); Eutrophic Children (EC) (11.00 ± 1.24 years old and BMI 17.51 ± 1.98); and Eutrophic Exercise (EE) (10.60 ± 1.06 years old and BMI 16.80 ± 2.53). OWE group practiced circus activities twice a week, during six months. CD95 and CD25 expression in CD4+ lymphocytes, DNA fragmentation and membrane integrity were evaluated by flow cytometry and proliferative capacity by incorporation of thymidine. **RESULTS** A higher lymphocyte proliferative capacity was observed in OWC and OWE groups when compared to EC (3509 ± 887.2; 2694 ± 560.4 and 1768 ± 208.2 cpm, respectively). The same was observed in comparison to EE (2313 ± 111 cpm) groups. In OWC group a lower expression of CD25 was found when compared with EC and EE groups (160 ± 44.63, 355.9 ± 109.6 and 341 ± 134, respectively). On the other hand, the OWE group (363.9 ± 151.0) presented a higher expression of CD25 when compared with the OWC group. In the CD95 expression, EC (953.9 ± 101.2) and EE groups (736.7 ± 194.6) showed higher values than the OWC group (522.1 ± 125) and OWE group (551.6 ± 144.5). **DISCUSSION** The present study indicates that a modification of immune system regulation occurs in overweight children. The decreased CD25 expression and increased proliferative capacity in non-stimulated cells may indicate an unbalance in lymphocyte regulation, once CD25 is related to regulatory T cell function. These cells are involved in the suppression of excessive activation of peripheral lymphocytes. In addition, a lower expression of CD95 is related to a fail in the inhibition of excessive lymphocyte proliferation. Furthermore, although circencis activities were not able to change the lymphocyte final response, CD25 expression was increased. These alterations indicate that overweight children are more prone to develop diseases related to

immune system function. References 1.Grom AA, Hirsch R. (2000). *Curr Opin Rheumatol*. 12, 420-424. SUPPORT: FAPESP,CAPES AND CNPQ

## CHARACTERISTICS AND EVALUATION OF QUALITY OF LIFE IN A GROUP OF PATIENTS UNDERGOING CHEMOTHERAPY TREATMENT

FERREIRA, E., SAÇO, L.F., LESSA, C., PAULA, O.R.

UNIVERSIDADE FEDERAL DE JUIZ DE FORA

**Introduction** Life's quality is a wide concept which includes the individual's perspective in relation to their objectives, their satisfactions and their concerns. The identification of quality of life of the oncologic patient, currently, is a fundamental source to measure the results of the treatment in the patient's perspective. His/her assessment allows the understanding of how different therapeutic interventions influence the patients' results (NICOLUSSI, 2010). Therefore, the goal of this research was to evaluate the quality of life of a patients' group with neoplastic disturbances neoplasms who are undergoing a chemotherapy treatment in Ascomcer Hospital, located at Juiz de Fora city. **Methodology** This study has as bases the transversal descriptive analysis of people with cancer who undergo a chemotherapy treatment. There were interviewed 40 patients of both sexes and who were starting their second chemotherapy session. The interview was executed through the questionnaire of life quality 'SF36.' **Results** We observed the female predominance in relation to the male, being the average age 57,4 years old. The breast cancer was the most frequent, attacking 60% of the patients, and soon afterwards the colorrectal cancer, representing 17,5%. The Functional Capacity was the item that obtained the larger index, 69,9% and in relation to the gender it obtained the result more significant taking into account the statistics. The Practice of Physical Activity was about four times bigger in women than in men considered in this study. This result can be related directly to the functional capacity variables, general health state, vitality, social aspects and mental health, because in these the scores found obtained higher medium between the adult women in relation to adult men. **Conclusion** That investigation was able to show that the aspects regarding the multiple dimension and to subjectivity, presented in the concept of Life Quality and represented by their respective domains, can be taken as the north because of the progress of the therapeutic possibilities and also because of the improvement in the prognostics for the cancer treatment. **References** CICONELLI, R. ## PHYSICAL EXERCISE AND PROSTATE CANCER: DESIGN AND METHODS

NILSEN, T., THORSEN, L., FOSSÅ, S.D., RAASTAD, T.

NORWEGIAN SCHOOL OF SPORT SCIENCES

**Introduction and aim** Prostate cancer (PC) growth is stimulated by the presence of androgens (testosterone). Hence androgen deprivation therapy (ADT) is an effective treatment in these patients. However, ADT has side effects, such as reduction in muscle mass and bone mineral density, increased fat mass, increased risk of fatigue and depression, as well as reduced quality of life. Physical exercise is therefore suggested as an effective counter measure against the listed side effects (1). Especially strength training, which counteracts the decrease in muscle mass and bone health, should be of great interest for prostate cancer patients undergoing ADT. To the authors best knowledge no studies has so far investigated the mechanisms behind the muscle wasting observed in ADT treated PC patients, or how cellular mechanisms are influenced by strength training. Consequently, the main aim of this part of the Physical Exercise and Prostate Cancer study (PEPC) is to investigate the effect of ADT alone or combined with strength training on satellite cells and myonuclei per muscle fiber, as well as androgen receptor and heat shock protein content in a leg muscle (m. vastus lateralis). **Study design** PEPC is a randomized clinical trial in which an exercise group (EG), following a four months supervised strength-training program aimed to improve muscular strength and hypertrophy, is compared with a control group (CG), following standard care and maintaining their habitual activity level. Patients in both groups undergoes strength tests and muscle biopsies at baseline (before first ADT injection), after six to nine months on ADT (pre-intervention assessment) and after the 16 weeks of intervention (post-intervention assessment). **Intervention** The EG perform three strength-training sessions per week, where one session is performed at 90 % of 10RM. After 2 weeks of low load familiarization to strength training, the following 14 weeks consists of 1 to 3 sets with 6-10 RM where the loads increases progressively. Nine exercises are performed: squat, leg press, standing calf raises, leg curl, leg extension, chest press, seated rowing, shoulder press and biceps curl. **Progress** Between January 2009 and February 2011, 55 patients have been included. So far 31 patients have completed the intervention; 14 in the exercise group and 17 in the control group. Eight patients have dropped out; four in the exercise group, two in the control group and two before randomization. Inclusion of patients will end during autumn 2011, and the last posttest will take place four months after. **Reference** 1. Galvao et al. *Prostate Cancer and Prostatic Diseases* 10: 340-346, 2007.

### PP-PM37 Resistance Training

## LACTATE THRESHOLD, VENTILATORY AND SURFACE ELECTROMYOGRAPHY IN RESISTANCE EXERCISE

FONTANA, K.

UNIVERSITY OF BRASILIA

**LACTATE THRESHOLD, VENTILATORY AND SURFACE ELECTROMYOGRAPHY IN RESISTANCE EXERCISE** Fontana KE.1, Nasser and Smith SV.1 **FA.2** 1: Laboratory of Exercise Physiology - College of Physical Education and 2: GPDS-Electrical Engineering, University of Brasilia **Introduction** Resistance exercise (RE) has been subject of several scientific studies, because what was done only for aesthetic purposes, now stands out for its contribution in promoting health and sports. To understand the determinants of RE is necessary to analyze the phenomena under the biochemical, biomechanical and physiological factors. The objective was to identify and compare the anaerobic threshold (AT) by lactacidemia, spirometry and surface electromyography (SEMG) in RE on curl biceps. **Methods** Thirteen healthy young adults with at least two months experience in ER ( $21.3 \pm 2.6$  years) performed incremental dynamic protocol resisted graded in fractions of 1 RM.

Blood samples were collected simultaneously (lactate), ventilatory and heart rate (Cardiopulmonary Spirometry) and SEMG (linear array of 16 channels). AT was determined by visual inspection of the curve of blood lactate (Wasserman and McIlroy, 1964), ventilation and ventilatory equivalents (O<sub>2</sub> and CO<sub>2</sub>) (Wasserman et al., 1973) and by the first break point of the linearity of the curve of SEMG speed conduction of the nerve impulse average over time (CV) based on the concept of maximum likelihood (Salomoni et al., 2007). The AT was expressed and compared in terms of VO<sub>2</sub>, HR, absolute and relative workload (kg, % 1RM). The coincidence between the methods was analyzed by repeated measures ANOVA and Bland-Altman method from the perspective of validating the SEMG to AT determination. Results and Discussion It was possible to identify the AT in all three methods. The SEMG was validated when compared to lactacidemia (gold standard). Aguiar et al. (2010) and Hendrix et al. (2009) also detected AT by SEMG (RMS and MMF) in isometric ER. In dynamic ER, Barros et al. (2004) and Azevedo et al. (2005) determined the AT (lactate) around 30% 1RM, higher than that found in this study (21.5% 1RM). The anaerobic threshold may have been postponed due to the training time of the subjects measured in these studies. More studies need to be made regarding the standardization of the methodological and analytical determination of AT. References Salomoni S, Soares FA, Nascimento FA, Veneziano WH, Rocha AF (2007). ## BLOOD LACTATE KINETIC IN CIRCUIT STRENGTH TRAINING

WIRTZ, N., KLEINOEDER, H., WECHSLER, K., KULZER, M., MESTER, J.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction For an interpretation of blood lactate concentration [La] in strength training it has to be known what kind of exercise structure and involved muscle mass produce and metabolize lactate. Our hypothesis is that lactate metabolism works better in repeated bouts of the same muscle group than in a combination of exercises of different muscle groups. Beside metabolism of lactate in heart, liver and brain, type 1 muscle fibres are dependent from the availability of lactate. Lactate transport in the same muscle group via cell-to-cell shuttle would predominate in multiple set training whereas lactate transport in blood during exercise of different muscle groups is handicapped by a restricted blood flow in the working muscle. The purpose of the study was to investigate the influence of a strength training with different muscle groups like Super Series or circuit strength training on [La] and lactate kinetics. Methods Ten male sport students (25±5years; 183±7cm; 76±23kg) participated at 3 different days in 3 different exercise protocols. Super Series (SS3) consisted of a 3 set agonist-antagonist exercise session i.e. Leg Extension (LE) and Leg Curl (LC). The subjects did 3 sets with 3min rest between the sets and 5s rest between the 2 exercises. The 1-set-circuit training (CT) consisted of 6 exercises i.e. LE, LC, Biceps Curl, Bench Press, Abdominal Press and Lat Machine with 1min rest between the exercises. Furthermore, 3-set-training with the Leg Extension (LE3) exercise was performed with 1min rest between the sets. Each of the bouts was performed with the 10 RM-defined additional load and a constant movement velocity of 4s per repetition. Before exercise was a warm up with 10 repetitions of 30% 10 RM. Lactate samples were taken at rest, immediately before and after each bout and 2, 4 and 6min after the last bout. Results CT leads to a continuous increase in [La]. In session LE3 [La] only increases in between the sets and is interrupted by stagnation or decrease during 2nd (3.7±1.0 to 3.5±0.6mmol/l) and 3rd (5.6±1.1 to 5.1±1.0mmol/l) set. In session SS3 [La] increases in between the sets. During the 1st and 2nd part (LE; LC) of set 2 and 3, [La] stagnates respectively decreases. Discussion The results support that multiple sets of the same muscle group (LE3) stimulate lactate metabolism of type 1 fibres in strained muscle. If muscle had high lactate production in a set before, the availability of lactate via cell-to-cell shuttle for metabolism during bout is greater than the availability via bloodstream during one after another bout of different muscle groups (CT). In alternately conducted exercises for 2 different muscle groups (SS3) lactate metabolism during set leads to stagnation of blood lactate also. Lactate metabolism in distal tissue like heart or distal seated type 1 fibres does not seem to rise in progression of exercises for different muscle groups. So CT reveals continuous increase of [La] during and in between the sets.

## ECCENTRIC EXERCISE AS A TOOL TO COMBAT OBESITY IN OVERWEIGHT INDIVIDUALS

THEODOROU, A.A.1.3, PASCHALIS, V.1, NIKOLAIDIS, M.G.2, PANAYIOTOU, G.3, FATOUROS, I.G.4, KOUTEDAKIS, Y.1, JAMURTAS, A.Z.1

1: UTH (GREECE), 2: CERETETH (GREECE), 3: EUC RC (CYPRUS), 4: DUTH (GREECE).

Introduction Most resistance exercise programs include dynamic repetitions with both concentric and eccentric muscle contractions. It has been reported that eccentric exercise can cause greater favorable changes on health parameters than concentric exercise (Pashalis et al., 2010). In addition, eccentric exercise produces less cardiovascular stress (Meyer et al., 2003) suggesting that it may be more suitable for overweight individuals. Methods Sixteen overweight females were allocated randomly into two equal-sized groups. Participants visited the laboratory once a week for four subsequent weeks to perform the isokinetic concentric or eccentric exercise protocol (5 sets of 15 maximal voluntary actions in each of their lower limbs in the seated position). Isometric, concentric and eccentric peak torque, were measured before and 3 days after the first and the last exercise session. Plasma triacylglycerols (TG), total cholesterol (TC), high-density lipoprotein cholesterol (HDL) and low-density lipoprotein cholesterol (LDL) were measured at the same points. Results Muscle strength decreased at day 3 only after the first exercise session in the eccentric group. By week 4, both training sessions increased resting muscle strength. Regarding blood lipid profile all indices were favourably modified at day 3 after the first session of exercise in the eccentric group only. By week 4, the resting levels of blood lipid profile in both groups were not significantly changed. However there was a trend for favorable changes in the eccentric group only. Discussion The greater gain in muscle torque that appeared after eccentric training could be partially attributed to the greater muscle hypertrophy that follows eccentric training compared with concentric training (Farthing and Chilibeck 2003). Therefore, it seems that eccentric training can induce health-promoting effects that may improve quality of life. However, more time than four week is needed before favorable changes in blood profile appear as reported after 8 weeks of eccentric training (Pashalis et al., 2010). ## BLOOD LACTATE KINETIC IN MULTIPLE SET STRENGTH TRAINING

WIRTZ, N., KLEINOEDER, H., BAUCSEK, S., MESTER, J.

GERMAN SPORT UNIVERSITY COLOGNE

**Introduction** Strength training increases blood lactate in between and after exercise. Metabolic disturbance and high lactate concentrations stand for adaptational processes in muscle. The altitude of blood lactate concentration [La] depends on production in working muscles, in particular of type 2 fibres. Furthermore, [La] depends on transportation via monocarboxylate transporter to other tissue, where lactate is used for metabolism. During exercise lactate transportation to proximal seated type 1 fibres has main relevance, because of restricted blood flow. The enhanced blood flow after exercise leads to a better distribution of lactate in body, so that lactate can be metabolized in distal tissues like heart, liver, brain and distal type 1 muscle fibers. Strained muscle volume and exercise structure influence [La] and lactate kinetic. The purpose of the study was to investigate the influence of strained muscle volume on [La] and lactate kinetics in between and after multiple sets of strength training with the same muscle group. **Methods** Ten male sport students ( $23 \pm 2$  years;  $180 \pm 5$  cm;  $73 \pm 8$  kg) men participated at 4 different days in 4 equal exercise protocols with different size of muscle volume i.e. Biceps Curl one armed (BC1), Biceps Curl two armed (BC2), Leg Extensor one legged (LE1) and Leg Extensor two legged (LE2). Each of 3 sets was performed with the 10 RM-defined load and a movement velocity of 2 s for both concentric and eccentric phase. Blood lactate samples were taken before training at rest (R) and immediately before (pre) and after (post) each set (pre 1, post 1, pre 2, post 2, pre 3, post 3) as well as 2, 4, and 6 min (post 3a, post 3b, post 3c) after finishing exercise. **Results** [La] was significantly higher after LE2 ( $6.8 \pm 1.6$  mmol/l) and significantly lower after BC1 ( $2.8 \pm 0.7$  mmol/l) in comparison with all other methods, respectively. There was no difference between BC2 ( $4.3 \pm 1.1$  mmol/l) and LE1 ( $4.4 \pm 1.1$  mmol/l). In progression of exercise procedure the post-values were getting smaller in comparison with the pre-values of each set. During the 3rd set of LE2 blood lactate concentration even decreased significantly ( $p < 0.05$ ) from pre 3 ( $5.8 \pm 1.5$  mmol/l) to post 3 ( $4.9 \pm 1.5$  mmol/l). The increase in between the sets was getting lower in exercise progression. **Discussion** It could be expected, that maximum in [La] depends on the strained muscle volume, so LE2 resulted in the highest values and BC1 in the lowest. Furthermore, higher [La] in progression of exercise session increases lactate metabolism in strained muscle, so [La] stagnated or even decreased during set 2 and 3. On the one hand lactate is metabolized particularly in heart and type 1 fibres in the strained muscle. On the other hand lactate elimination from type 2 fibres to blood is limited by restricted blood flow with the result of high peak of metabolic stress in muscle. High peak of metabolic stress in muscle could be one important factor for adaptational processes in strength training.

## STRENGTH TRAINING CONTROL BY MEANS PEAK POWER CRITERIA IN ELITE FUTSAL SPANISH PLAYERS DURING A SEASON

TUR CARBONELL, C., GONZÁLEZ-HARO, C.

DEPARTMENT PHARMACOLOGY AND PHYSIOLOGY

**Introduction** Training in athletes with peak power criteria has been proposed in some studies (Izquierdo et al., 2002; 2004). It has been suggested that linear encoder may be valid to control muscle power adaptations in sport (Gaasvaer & Bahr, 1999). Nevertheless, there do not exist any study that had controlled the strength training by means peak power criteria in elite Futsal players. Thus, the purpose of the present study was to control the strength training by means the criteria of peak power in leg press during a training season. **Methodology** 12 elite Spanish futsal players carried out three progressive test in leg press at 20, 40, 60 and 80% 1RM estimated (Brzycki, 1993). Mechanical power (expressed in watts (W)) of each repetition was measured and recorded by means Muscledab system (Ergotest innovation, Norway). Power curves were plotted using average power over the whole range of movement in concentric mode in leg press. The first test was carried out at the beginning of the training season (T1), the second one 3 months after (T2), and the third one 6 months after respect to the first one (T3). The average of the peak power of each repetition of all trainings during the whole season were quantified (TL1: training load corresponding to 2 months before the first test, TL2: training load corresponding to 3 months before the second test, and TL3: training load corresponding to 3 months before the third test). All players performed 1 or two strength training sessions per week at the gym in leg press (3 sets of 5 repetitions, around 90% of peak value of power: T1:  $91 \pm 4\%$ , T2:  $89 \pm 6\%$ , and T3:  $91 \pm 4\%$ ) during the whole training season. Comparisons between variables were made by means a repeated measured ANOVA. Statistical significance was set at  $p < 0.05$ . **Results** Peak power training was controlled during all training season (LT1:  $1132 \pm 139$  W, LT2:  $1153 \pm 141$  W, and LT3:  $1171 \pm 140$  W), although during LT3 players performed higher training intensity respect to LT1 ( $p < 0.01$ ). It was not found significant differences for peak power expressed in kg (T1:  $137 \pm 11$  kg, vs. T2:  $145 \pm 7$  kg, and T3:  $144 \pm 6$  kg). In spite of there were no significant differences for peak power between T2 ( $1212 \pm 114$  W) and T3 ( $1229 \pm 130$  W), there were differences between T1 vs. T2 ( $1156 \pm 133$  W vs.  $1212 \pm 114$  W,  $p < 0.05$ ) and T1 vs. T3 ( $1156 \pm 133$  W vs.  $1229 \pm 130$  W,  $p < 0.05$ ). Then peak power increased 4.6% and 5.9% since T1 vs. T2 and T1 vs. T3, respectively. **Conclusions** The present study suggests that to perform 1 or 2 strength training sessions around 90% of peak power is sufficient stimulus to improve peak power in elite futsal players at least until the middle part of the training season. **References** Brzycki M. ## BLOOD LACTATE CONCENTRATION DURING THREE DIFFERENT CIRCUIT WEIGHT TRAINING PROTOCOLS IN MEN AND WOMEN

BAVARESCO, N., CUPEIRO, R., PEINADO, A.B., MORENCOS, E., BUTRAGUEÑO, J., CALDERÓN, F.J., BENITO, P.J.

UNIVERSIDAD POLITÉCNICA DE MADRID

(Clinical trial gov number: NCT01116856) **Introduction** Differences in lactate concentration between genders have been quantified during resistance exercise 1, but never during Circuit Weight Trainings (CWT), neither comparing different protocols at the same intensity. Therefore, the aim of this study was to compare venous blood lactate concentrations in men and women during three different CWT. **Methods** 15 men ( $22.53 \pm 2.59$  years;  $76.66 \pm 6.45$  kg;  $177.21 \pm 3.77$  cm) and 14 women ( $20.14 \pm 2.88$  years;  $60.38 \pm 5.43$  kg;  $164.36 \pm 5.06$  cm), all healthy, non-smoking and active, performed three different CWT: Machine Circuit (CM), Free Weight Circuit (FW) and Combined Aerobic-Free Weight Circuit (CE). The CWT consisted on three laps of eight 8 exercises, trying to involve the same muscular groups. The intensity was set at 70% of 15 RM and 70% of the HRR during the aerobic phases. Venous blood samples were analyzed immediately after each lap and every two minutes in the recoveries between laps, using the YSI 1500 SPORT lactate analyser. Three way ANOVA with repeated measures was used to determine differences between protocols and genders. The significant level was set at  $\alpha \leq 0.05$ . **Results** We found interaction among gender, protocol and measurement ( $F(8.554) = 4.524$ ,  $p < 0.001$ ). The analysis showed significant higher lactate values

for men in all the measurements ( $p < 0.001$ ), and significant lower concentrations in CE compared to the others protocols ( $p < 0.001$ ). Furthermore, we found some significant differences between MC and FWC, especially at the end of the session. Discussion Our data are in agreement with previous studies, reporting higher values in men than in women 1-2. This could be due to the higher fibre I muscle percentage in women 3, the hormonal state 4-5 or the greater relative external load lifted by men 2. We have also found less lactate concentration during CE, perhaps due the aerobic phase that helped lactate oxidation 6-7. Therefore, we can conclude that during CWT men have higher lactate concentrations than women, and that anaerobic contribution depends not only on the intensity of the session but also on the protocol used, and this influence is presented in both genders. ## HUMAN SKELETAL MUSCLE REMODELING WITH ECCENTRIC AND CONCENTRIC TRAINING

FRANCHI, M.V., REEVES, N.D., FLÜCK, M., NARICI, M.V.

MANCHESTER METROPOLITAN UNIVERSITY

**Introduction** Muscle hypertrophy and strength gain are the most evident consequences of concentric and eccentric resistive training. The responses to these two training modes may only be compared for loading protocols matched for neural activation. This fundamental requirement, stipulated by the FORCE-VELOCITY relation [1, 2], is normally not met by conventional resistance training, since the same absolute load is displaced in the concentric and eccentric phases. Hence motor units must necessarily be de-recruited in the eccentric phase to enable the load to be lowered. Therefore, the aim of the study was to investigate the structural and functional adaptations of human skeletal muscle (Vastus Lateralis - VL) in response to pure eccentric and concentric training when matched for neural activation. **Methods** Twelve young healthy males were assigned to a pure concentric (CG) or pure eccentric (EG) resistance-training group. Training consisted of 4 series of 8-10 repetitions with a load of 80% of the concentric (CG) or of the eccentric (EG) 1RM performed on a leg-press machine (Technogym). Maximum voluntary isometric contraction (MVC) torque was measured from 90° to 150° of knee extension. Muscle volume (VOL) was measured using MRI and muscle architecture (fascicle length, Lf, and pennation angle) was assessed in vivo by ultrasonography. Results Training increased muscle volume in both groups, but the increase was two-fold greater in the CG (10%) compared to the EG (5%); an increase in fascicle length was observed in both groups but significantly greater in the EG (12%) compared to the CG (5%). Conversely, pennation angle increased more in the CG than in the EG (30% and 5% respectively). Physiological cross-sectional area (PCSA) increased by 5% in the CG but paradoxically decreased in the EG after the training period, may due to the relatively greater increase of Lf compared to muscle volume in the EG. Isometric MVC increased similarly after both types of training (CG = 9%; EG = 11%). Discussion These findings show that eccentric and concentric training, when matched for neural activation, lead to markedly different structural adaptations of human skeletal muscle. This observation suggests that separate myogenic mechanisms are triggered by the two of contraction modes. This hypothesis seems consistent with findings of different muscle cell signaling responses to concentric and eccentric loading in animal skeletal muscle [3, 4]. References 1-Hill AV. ## CHANGE IN THE IMMEDIATE POST-EXERCISE BLOOD PRESSURE RESPONSE AFTER ISOMETRIC EXERCISE TRAINING AND ITS RELATIONSHIP WITH REDUCED RESTING BLOOD PRESSURE

WILES, J., SWAINE, I., DEVEREUX, G., HOWDEN, R., MCCARTNEY, N., COLEMAN, D.

CANTERBURY CHRIST CHURCH UNIVERSITY

**Introduction** The cessation of exercise is known to provide a unique challenge to blood pressure control. There have been suggestions that this challenge might provide the stimulus for reductions in resting blood pressure following isometric training. Therefore, there were two purposes to this study (a) to identify changes in the immediate post-exercise blood pressure responses (IPER) before vs. after isometric training and (b) to relate these changes to the training-induced reductions in resting blood pressure. **Methods** 11 subjects were asked to participate in a 4-week double-leg isometric training study. Before and after the training the immediate post-exercise blood pressure response (IPER) to 2 minutes of double-leg isometric exercise at 22%MVC was investigated. Systolic (SBP), diastolic (DBP) and mean arterial (MAP) blood pressures were recorded continuously using finger plethysmography (Finometer). Individual blood pressure values were established at 20s intervals throughout a 5 minute post-exercise period and pre- to post-training changes in IPER at 1, 2, 3, 4 and 5 minutes were established and correlated with reductions in resting SBP, DBP and MAP after training. Results The 5-minute IPER appeared to be tri-phasic, with the greatest relative change in IPER, after training, at 2 minutes ( $-3.11 \pm 7.58\%$ ). However, this relative change was not correlated with the reductions in resting blood pressure. Rather, the 5-minute IPER relative change after training, although much smaller, was strongly correlated with the reductions in resting SBP ( $r=0.76$ ;  $p<0.01$ ). Discussion These findings raise the possibility that (i) the mechanism responsible for the reductions in resting blood pressure after isometric training might involve physiological systems similar to those involved in the IPER (ii) the 5-min IPER could be used as a simple indicator of the efficacy of isometric training in reducing resting blood pressure and (iii) accentuating the post-exercise blood pressure challenge might enhance the reductions in blood pressure observed after isometric training.

## RESISTANCE TRAINING WITH LOWER VELOCITY LOSS WITHIN A SET PRODUCES GREATER STRENGTH GAINS COMPARED WITH HIGHER VELOCITY LOSS

PAREJA-BLANCO, F., SÁNCHEZ-MEDINA, L., SUÁREZ-ARRONES, L., GONZÁLEZ-BADILLO, J.J.

PABLO DE OLAVIDE UNIVERSITY

**RESISTANCE TRAINING WITH LOWER VELOCITY LOSS WITHIN A SET PRODUCES GREATER STRENGTH GAINS COMPARED WITH HIGHER VELOCITY LOSS** Pareja-Blanco, F.1, Sánchez-Medina, L.1, Suárez-Arrones, L.1, González-Badillo, J.J.1 1:UPO (Seville, Spain) **Introduction** One variable whose role has not been sufficiently investigated when designing resistance training (RT) programs is movement velocity (Izquierdo et al., 2006). We have recently shown that velocity loss can be used to quantify neuromuscular fatigue during RT (Sánchez-Medina and González-Badillo, 2011). This study aimed to examine the effect of training with different mean repetition velocity losses on strength performance. **Methods** Sixteen strength-trained male professional soccer players (mean(SD): age 23.8(3.5) yr, body weight 75.0(8.5) kg, body fat 11.8(1.9)%, muscle mass 48.3(1.9)%), were randomly assigned to one of two groups: 15% (V15; n=8) or 30% (V30; n=8) velocity loss. Subjects trained during 7 wk for a total of 18 sessions following a periodized RT program using the full squat. The two groups trained at

the same relative intensity in each session (increasing from 50% to 70%RM over the course of the study) but differed in the maximum percent velocity loss allowed in each set (15% vs. 30%). When this limit was exceeded the set was terminated. Subjects were required to perform each repetition at maximal velocity. Velocity was monitored in each session and visual and auditory feedback provided in real time by means of a linear velocity transducer sampling at 1,000 Hz (T-Force System, Ergotech, Spain). A t-test for paired samples was used to compare mean differences between groups. Results Both mean number of repetitions per set (6.0 for V15, 10.6 for V30) and total number of repetitions performed (260.3 for V15, 435.1 for V30) were significantly lower for V15. Following training, the V15 group obtained significant increases ( $p < 0.05$ ) in 1RM strength (12.7%), maximum (13.5%) and mean power output (9.9%), whereas for V30 there were no significant increases in any of the variables analyzed. Discussion These findings indicate that short-term velocity-based resistance training using a 15% velocity loss limit seems to produce greater neuromuscular performance improvement compared to a 30% velocity loss limit in experienced professional soccer players. Conceptually, this would stress the importance of finding the optimal training volume during RT. The results suggest that performance improvements can be compromised when a given threshold of training volume is exceeded (González-Badillo et al., 2006) and that using a moderate number of repetitions not to failure provides a favorable environment for achieving greater strength increases. ## EFFECT OF KETOGENIC DIET ON EXPLOSIVE STRENGTH PERFORMANCE IN ELITE ARTISTIC GYMNASTS

PAOLI, A.1,2, GRAINER, A.1, BIASIO, C.2, CENCI, L.3, MORO, T.2, BIANCO, A.4

1 AND 2 UNIVERSITY OF PADOVA; ; 3 S. BORTOLO HOSPITAL, VICENZA; 4 UNIVERSITY OF PALERMO

Introduction Despite the increasing use of low carbohydrates/ketogenic diets (KD) on weight control and management of metabolic syndrome (Westman et al., 2007) there are paucity of researches about effects of KD diets on sport performances (Phinney et al., 1983a, 1983b). KD diets maybe useful in sports with weight class divisions. The aim of our study was to investigate the influence of KD on explosive strength performance, specifically in elite artistic gymnasts. Methods 8 male subjects (age 20.9 +/- 5.5 yrs) were recruited. Several physical and performance tests (body composition analysis, hanging straight leg raise, ground push up, parallel bars push up, pull up, squat jump, countermovement jump, 30 sec continuous jumps) were administered before and after 20 days of KD with support of phytoextract (Tisanoreica Diet; Paoli et al., 2010). During the KD the athletes consumes less than 20g of CHO per day and performed the normal training program. After three months the same protocol of tests (during a similar training period) was performed before and after 20 days of typical mediterranean diet. Results We utilized a repeated-measure t-test. No significant differences were detected between KD and Mediterranean diets in Squat Jump, countermovement jump, parallel bars push up and pull up but there are nearly significant increase during KD in ground push up and hanging straight leg. A more clear significant differences were detected on body composition: after KD there was a decrease of Kg of fat (from 4.95 +/- 1.05 to 3.92 +/- 1.05  $p < 0.019$  and a decrease of fat percentage (from 7.40 +/- 1.43 to 5.74 +/- 1.43  $p < 0.01$ ) with a contextual slightly but non significant increase in muscle mass. Discussion Despite concerns of coaches and doctors about the possible detrimental effects of low carbohydrates diets on performances and the well known importance of carbohydrates on performance (Maughan et al., 1997) there are no data about KD and explosive strength performance. The undeniable and sudden effect of KD on fat loss maybe useful for those athletes who compete in sports based on weight class. We've demonstrated that using KD for a short time period (i.e. 20 days) has no negative effect on explosive strength performance. References Maughan RJ et al., (1997). J Sports Sci, Jun;15(3):265-75. ## ENERGY EXPENDITURE INCREASES AFTER STRENGTH TRAINING IN COMBINATION WITH PROTEIN SUPPLEMENTATION IN NON-STRENGTH-TRAINING ADAPTED HEALTHY SUBJECTS

PLATEN, P.1, GROTHEER, K.1, VOLKE, J.1, MAREK, E.1, MANCHADO, C.2, HINRICHS, T.1

1INSTITUTE OF SPORTS MEDICINE AND SPORTS SCIENCES,2FACULTY OF EDUCATION, UNIVERSITY OF ALICANTE, SPAIN

Introduction: It is well known that post-exercise energy expenditure (EE) is increased after high-intensity resistance training (HRT). One study recently could demonstrate that protein supplementation could additionally increase 24h- and 48h-EE after a single strength-training bout in strength-training adapted people. However, it is not clear whether this effect also exist in non-strength-training adapted moderately trained sport students. Therefore, the aim of this study was to investigate the additional effects of an oral protein supplementation plus an acute bout of HRT on acute and longer-lasting EE. Methods: Six healthy resistance-untrained sport students (four men and two women) participated in a blind cross-over-design. All subjects completed a protein trial (PROT) and a placebo trial (PT) in a randomized order. REE and RER were measured on three consecutive days at the same time in the morning (7:00, 8:00, or 9:00 a.m.). On the first day after baseline measurements, subjects consumed a protein-rich (PROT) liquid supplement (13.7 g of carbohydrate, 0.9 g of fat, 38.2 g of protein; 205 kcal (mean ± sd), or placebo (PL) liquid supplement (13.7 g of carbohydrate, 0.9 g of fat, 9.7 g of protein; 103 kcal (mean ± sd) 30 min before a single bout of HRT (6 exercises, 4 sets, 12 reps., 70% 1-RM). REE and RER were measured 24h and 48h after HRT using indirect spirometry. Immediately after HRT, EE was measured for 3.5 h at fixed time points, again using indirect spirometry. Results: Energy expenditure during the training was the same for HRT after PROT and PL (EE (kcal/kg/day): PROT: 120.6±9.0, PL: 122.1±8.5). REE was significantly elevated 24h and 48h after PROT and HRT ( $p \leq 0.05$ ), while REE was only elevated 24h after HRT in PL ( $p \leq 0.05$ ), but not 48h later (baseline-, 24h-, and 48h-values for REE (kcal/kg/day): PROT: 24.1±0.8, 28.5±1.6, 27.5±1.3; PL: 24.6±1.2, 26.3±2.3, 25.0±1.6). Acute post-exercise EE was significantly higher in PROT as compared to PL from 0.25h to 0.75h and from 1.75h to 2.25h after HRT ( $p \leq 0.05$ ). We could not detect any differences in RER in both PROT and PT 24h or 48 h after HRT compared with baseline ( $p > 0.05$ ). Conclusions: The intake of a protein-rich energy supplementation lead to a longer-lasting increase in energy expenditure after one single bout of high resistance training in non-strength-training adapted sport students, indicating ongoing muscle-building processes when amino acid availability is high enough. This study clearly supports the concept of combining strength training and protein supplementation even in non-strength-training-adapted moderately trained people.

### PP-PM38 Children and Physical Activity 1

#### LONGITUDINAL CHANGES IN PHYSICAL ACTIVITY OVER TWO YEARS IN YOUNG CHILDREN

WOLLMER, P.

LUND UNIVERSITY

Background: Limited information is available about changes over time in objectively measured daily physical activity in young children. This study evaluates if accelerometer-measured physical activity tracks or changes over two years. Methods: Daily physical activity was assessed by the Actigraph accelerometer for four consecutive days in 167 children (boys n=90, girls n=77) aged 7.9-11.1 years at baseline. Follow-up measurements were performed 2.0±0.1 yrs later (range 1.9-2.1 yrs). General physical activity (GPA) was considered to be mean count per minute. Minutes of light physical activity (LPA), moderate physical activity (MPA), moderate and vigorous physical activity (MVPA) as well as vigorous physical activity (VPA) per day were calculated. Results: Spearman rank order correlation indicated low-moderate tracking of MPA, MVPA, VPA in both boys and girls, and GPA in boys ( $R=0.24-0.40$ ,  $P<0.05$ ). No significant tracking was detected for LPA, and GPA in girls. Several physical activity variables were lower at follow-up: In girls; LPA (-12%), and in boys; GPA (-14%), LPA (-10%), and VPA (-27%). Conclusion: This study shows that accelerometer-measured physical activity tracks at a low-moderate degree from age 10 to age 12 years. It is of concern that several physical activity variables were lower at follow-up in both boys and girls.

#### OBESITY INDICES AND PHYSICAL SELF-DESCRIPTION OF SECONDARY SCHOOL CHILDREN AGED 13 TO 15 YEARS OLD

ELIADES, K., DOUDA, H., TOKMAKIDIS, S.P.

HEALTH-EDUCATION OFFICE OF SECONDARY SCHOOLS IN RODOPI

Introduction Obesity often leads to changes in personality and behaviour of children as manifested in the form of depression, withdrawal and low self-esteem (Biddle & Armstrong, 1992). The self in adolescence is shaped primarily by social interactions of adolescents, through which the self-image is changing to respond to differences between the way that they perceive themselves and the reactions of others. The aim of the present study was to assess the obesity idiocies and physical and global self-esteem of overweight/obese adolescents. Methods 125 healthy pupils (52 males and 73 females), aged 14.5±0.8 yrs, participated in the study and were divided according to their gender (male, female) and their obesity (normal, overweight/obese) as defined by IOTF criteria (Cole et al., 2000). Anthropometrical measurements (BMI, body composition, abdominal circumference) were obtained and a physical self-description questionnaire (PSDQ) was applied which composed on seventy questions about strength, body fat, activity, endurance and fitness, sport competence, coordination, health, appearance, flexibility, general physical self-concept, and self-esteem (Marsh et al., 1994). Results From the PCA analysis, six components were extracted, with eigenvalue above 1, explaining 69.84% of the total variance, and were labelled in the following order: 1-Physical self-esteem (16.81%), 2-Low Self-Esteem (15.85%), 3-Total self-esteem (13.75%), 4- Sports Competence (12.96%), 5- Endurance (5.87%) and 6-Health (4.59%). The data analysis showed that there are significant differences between males and females in physical self-perception factors ( $p<0.01$ ) and low confidence ( $p<0.05$ ). Also, significant difference were observed among overweight/obese and normal body mass children in their views concerning physical fitness ( $p<0.05$ ), total self-esteem ( $p<0.05$ ) and low confidence ( $p<0.001$ ). In addition, Pearson correlation coefficients showed statistically significant association of BMI with physical factors of self-esteem ( $r=-.294$ ,  $p<0.01$ ) and low self-esteem ( $r=.704$ ,  $p<0.001$ ). Similar correlations showed respectively, the percent body fat ( $r=-.315$  &  $r=.458$ ,  $p<0.01$ ), while the abdominal circumference was associated only with low confidence factor ( $r=.543$ ,  $p<0.001$ ). Discussion These results indicate that overweight/obese children differ in overall self-esteem than children with normal body mass. Moreover, the fact that indicators of obesity were associated significantly with the physical self-esteem and low self-esteem suggests that exercise and participation in various types of physical activity can modulate the levels of perceived athletic competence and self-esteem enabling overweight/obese teenagers to reinforce the image of their physical and overall self-esteem. #### CHILDREN'S PHYSIOLOGICAL AND METABOLIC RESPONSES TO GUIDED ACTIVE PLAY

MORRISON, K.1, BELCASTRO, A.2, SHANNON, C.1, HICKS, E.1

1: UNIVERSITY OF NEW BRUNSWICK (FREDERICTON, NB, CANADA), 2: YORK UNIVERSITY (TORONTO, ON, CANADA).

Introduction Many suggest that play is the single most effective strategy for increasing physical activity among children and adolescents (Active Healthy Kids Canada, 2009). Whether children's games, when organized into a guided active play (GAP) session, sufficiently engages children in moderate-vigorous (MVPA) to vigorous (VPA) physical activity, is uncertain. The purpose of the study was to determine the volume (kcal) and intensity (kcal/min, METs, %HRM) of 10 children's games on different days (r). Methods Children (9.8±0.9 yrs) were assessed for VO<sub>2</sub>, HR, VCO<sub>2</sub>, RER, energy expenditure (EE) and METs on a treadmill (for 3 min each at 4, 6 and 8 km/h (0% grade)). Accelerometers were validated and equations estimated kcal and METs of 10 games performed during 4 guided active play sessions (1hr each). Results Average EE across all games was 0.055±0.011 kcal/kg/min of playing; with a range of 0.039 kcal/kg/min to 0.071 kcal/kg/min of GAP ( $p<0.05$ ). HR averaged 75% HRM, with a range of 53-89%HRM. Percent of time playing at moderate (4.5-6 MET) and vigorous (>6 MET) activity ranged from 14% to 36% ( $p<0.05$ ) across all games. Volume and intensity levels of the same games played on different days were similar ( $p>0.05$ ). Discussion This study confirms the potential benefits of guided active play to positively contribute to the caloric expenditure and intensity levels required of children and adolescents in support of health and fitness. Moreover, guided active play creates an environment that allows for the amount and intensity of physical activity for children playing self-directed games to be similar from one session to the next. These results are encouraging considering they were accomplished in a safe, fun and social environment that supports the development of a child's self-confidence in relation to being physically active. It has been reported that participating in a free a guided active play environment contributes positively to a child's self- confidence and social development and contributes to their satisfaction with participation (Henle, 2007). ### CORRELATION BETWEEN OBESITY, FITNESS AND BEHAVIORAL FACTORS IN SCHOOLCHILDREN OF CITY OF FRANCA-SP, BRAZIL.

NAVAS, A.P.1, ZAIA, J.E.1, CARVALHO, A.S.1,2, TONELLO, M.G.M.1,3, CAMPOS, P.A.3, RAMOS, L.F.A.O.4,5, NEIVA, C.M.1,6  
 1: UNIFRAN (FRANCA-SP), 2: UNIARAXÁ (ARAXÁ-MG), 3: UNAERP (RIBEIRÃO PRETO-SP), 4: FESP-UEMG (PASSOS-MG), 5: FMRP-USP-NEUROLOGIA (RIBEIRÃO PRETO-SP), 6: UNESP (BAURURU-SP)

**Introduction** The substantial increase in the prevalence of obesity and its related diseases such as heart disease, hypertension and diabetes is due largely to the two variables are behavioral: low levels of habitual physical activity and sedentary behaviors. This study sought to identify the relation between obesity, usual level of physical activity and sedentary behaviors in schoolchildren aged 11 to 12 years in the city of Franca- SP. **Methods** Participated of the study 77 students of three public schools. Were used as indicators of obesity the body mass index (BMI), fat percentage and waist to hip ratio (WHR). The usual level of physical activity and sedentary habits were estimated by cardiorespiratory fitness assessed by the Cooper test and questioner. To analyze the relationship between obesity and behavioral factors (physical activity and sedentary habits) and cardiorespiratory fitness test was used Pearson correlation. The analysis was conducted using the statistical software GraphPad InStat® for Windows® and the significance value of 0.05 was adopted for all statistical procedures. **Results** The percentage of obesity found in the sample was 10.4%, 7.8% and 22.1% according to BMI, fat percentage and WHR, respectively. With respect to cardiorespiratory fitness, 62.3% of students fell into category 'Low'. Of the three measures of body fat used in the study, two were highly correlated with the level of physical fitness: BMI and fat percentage. The observed association with WHR was not significant. **Discussion** The negative correlation between cardiorespiratory fitness and obesity supports the hypothesis that excess weight has an inverse relationship with the level of cardiorespiratory fitness. This fact can be explained because children are overweight spend much energy and greater efforts in the movement of their bodies that is outside the normal range, compared to their non-obese peers. This condition seems to discourage the obese children the practice strenuous and/or long-lasting activities, thus contributing to a vicious cycle of weight gain.

### INFLUENCE FACTORS ON PHYSICAL ACTIVITY PROGRAMS PARTICIPATION AMONG DIFFERENT AGE'S GROUPS

BRÁS, R.1, ESTEVES, D.1, O'HARA, K.1, RODRIGUES, R.G.2, PINHEIRO, P.2

(1)UNIVERSITY OF BEIRA INTERIOR/CIDESD (COVILHÃ, PORTUGAL) (2)UNIVERSITY OF BEIRA INTERIOR/NECE (COVILHÃ, PORTUGAL)

**Introduction:** Despite the implementation of a several global and local policy strategies to promote physical activity (PA), the most European adults are insufficiently physically active for optimal health benefits. Investigation considers identification of preferences and individual goals regarding exercise programs one of the main aspects that influence PA participation patterns (Buman et al., 2010). The aim of this study was to evaluate the participation level on local exercise programs and compare the most valued factors that influence the participation on those programs, among different age's groups. **Methods:** The study included a randomly recruited sample of 745 subjects (53% males and 47% females), classified in 4 age groups: young(Y) (15-24years, n=185); young adults(YA) (25-39years, n=182); adults(A) (40-60years, n=201); older(O) (>61years, n=177). A survey was specifically designed to evaluate the participation on local exercise programs and to examine different factors (personal, environmental and program-related) associated to exercise participation. This survey was applied on interview form using a Likert scale (1-5). Age groups were compared used Chi-Square test (95%) and the factors proportions for dependents groups were compared used Cochran's Q test (95%). **Results:** 82±2% of sample rarely or never participated on the local exercise programs and the regular participation level tends to decrease with the age with significant differences after 40 years age (Y-13%; YA- 11%; A-5%; O-7%). No significant age differences were found for the following factors: price (47±2% ), structures facilities (47±3%), instructors formation (33±4%) and uninteresting activities (24±3%). However, lack of time (71±4%), scheduling (57±5%) and teaching methodology (34±1%) are significantly more appointed by Y, YA and A groups. Local proximity (37%) is significantly more referred by older people (O) (p<0.05), and social environment is more suggested by YA age group (21%) (p<0.05). **Discussion:** Despite the several health benefits from exercise, the majority of the subjects show a very low participation level on local exercise programs. Lack of time, price and scheduling are the most important influence factors found in this study, according with Epstein and Roemmich (2001). However the results indicated that the type of physical activities and the teaching methodology could also influence on exercise programs participation. Some differences on participation factors were found among age's groups, according their needs and social characteristics. These factors must be considered on exercise programs prescription to create a stronger motivation and adherence to a active live style. **References:** Buman P, Daphna L, Yasova P, and Giacobbi Jr (2010). ### INVESTIGATING THE DIFFERENCES BETWEEN OBESE AND NON-OBESE CHILDREN ON PHYSICAL ACTIVITY

PASCHALERI, Z., ARABATZI, F., KOIDOU, I., AVGERINOS, A.

LABORATORY OF NEUROMECHANICS

**Introduction:** There is an increasing prevalence of obesity among children (1). While some studies have examined the association between physical activity (PA) as a behavioral risk factor and overweight in older children, few studies have been conducted in young children (1). There are diverging findings in previous studies of PA and obesity in children, because of the different methods that have been used to assess daily physical activity. Eston et al. (2) have been shown that a triaxial accelerometer provides the best assessment of activity in children. The purpose of this study was to investigate the differences between obese and non-obese children 7-8 years old on PA with the use of triaxial accelerometer. **Method:** Seventy two children (age  $7.6 \pm 0.4$ ) participated in this study. BMI was used as obesity indicator. Children were categorized as non-obese (G1) and overweight/obese (G2) group, according to the age-adapted values. Daily PA was assessed by RT3 (Stayhealthy Inc, Monrovia, CA) for 4 consecutive days (two weekdays and a weekend). Total daily counts were calculated. Activity counts were classified according to moderate (3-5.9 METs) and vigorous (>6 METs) intensities. Analysis of variance with repeated measures was used to assess differences in total daily PA and in the average time spent in moderate and vigorous PA through four different days, according to BMI status. **Results:** There were no significant differences in the average daily total counts of PA and in the average daily minutes of moderate and vigorous activity in G1 and G2 but there were significant differences in minutes of moderate and vigorous activity between weekdays and weekend in both groups (P<0.05). The frequency of G1 who met the international recommendation of one hour of moderate to vigorous activity per day was 96.9% on weekdays and 90.65% at the weekend. However, the frequency of G2 was 92.6% on weekdays and 83.35% at the weekend. **Discussion/conclusion:** To our knowledge, this is the first study which has examined objectively measured PA of non-obese and overweight/obese children 7-8 years old with triaxial accelerometer.

From our results it seems that at this age PA is not the main contributing factor in childhood obesity. However, a non-significant trend of fewer minutes spent in moderate and vigorous PA in higher BMI categories and the smaller frequency of overweight/obese children who met the recommendation of 60 minutes of moderate to vigorous activity per day, shows that intervention PA programs should be planned for overweight/obese children even at a young age, and with special focus on more activity at the weekend. ### ASSOCIATIONS BETWEEN CHANGE OF PHYSICAL FITNESS AND CHANGE OF LIFESTYLE HABITS IN JAPANESE ADOLESCENTS: AN EXAMINATION OF THE DOSE-RESPONSE RELATIONSHIP

SUZUKI, K.1, NISHIJIMA, T.2, SUZUKI, K.3

1: TOHOKU GAKUIN UNIVERSITY, 2: UNIVERSITY OF TSUKUBA, 3: INTERNATIONAL BUDO UNIVERSITY

**Introduction** Most studies related to lifestyle habits of adolescents have focused on associations with health outcomes. It has been reported that there are associations between physical fitness and several health outcomes in adolescents (Ortega et al., Int J Obes 2008, 32: 1-11). However, literature focusing on the association between physical fitness and lifestyle habits, and the dose-response relationship, is scarce. And also, there is a need for longitudinal studies, since the previous study was based on a cross-sectional survey which provided only limited information about the changes in lifestyle habits and the physical fitness of adolescents. Therefore, the purpose of this study was to examine the associations between a change of lifestyle habits and a change of PF in Japanese adolescents, and to clarify the dose-response relationship. **Methods** The participants were 279 Japanese adolescents aged 11-13 (145 boys, and 128 girls). Data were collected three times; once a year over a three-year period. Survey items included eating habits (3-point ordinal scale: eating breakfast every day; 3, sometimes; 2, never; 1), physical fitness (Japan Fitness Test: Grip Strength, Sit-ups, Sit & Reach, Side Steps, 20m Shuttle Running, 50m Dash, Standing Long Jump, and Handball Throwing). Physical fitness in participants was graded into five categories according to norm-referenced criteria. A chi-square test and A latent growth modeling (LGM) were used to examine the influence of the change in lifestyle habits score to a change in a physical fitness score. In the LGM, the intercept term provides the initial level of scores and the slope describes how much a score was changed from initial value over time (Park and Schutz, RQES 2005, 76: 176-192). Statistical significant was set at .05. **Results** The results of a chi-square test showed that there were two significant associations; the first between being poorly-fed (having poor eating habits) and a decline in total fitness score (Chi-square (4) = 10.40,  $p < .05$ ), and the second between the decline in TV/video game viewing time and improvement in the total fitness score (Chi-square (4) = 22.89,  $p < .05$ ). Results for LGMs indicated good fits to the data (e.g., CFI = 1.000, RMSEA = .000, respectively). A latent growth model analysis revealed that an improvement in eating habits was significantly related to an improvement in the total fitness score (Unstandardized coefficient: 1.13, SE = .55). **Conclusions** These findings, which are limited to the statistical method used in the study, might suggest the following: 1) changes eating habits and TV/video game viewing habits are associated with a change in physical fitness, 2) the annual increase in the rate of the total fitness score in the group that improved eating habits was 1.13 points higher than the other groups. This study was supported by the Japan Society for the Promotion of Science (Grant-in-Aid for Young Scientists B: 21700673).

### LOWER LIMB POWER IN OVERWEIGHT AND NORMAL WEIGHT CHILDREN

FERUNAJ, P.

UNIVERSITY OF SPORTS OF TIRANA

Ferunaj, P., Çina, R., Erindi, A. University of Sports, Tirana (Albania) **Introduction** It is obvious that physical inactivity is a contributing factor for childhood overweight (1) and low physical fitness (2). During their leisure time children perform more short term high-intensity exercises, such as jumping events or racket sports than long-term activities (3). Very few studies reported the relationship of body weight with anaerobic power in children, expressed in jumping. **Methods** A random sample of 40 Albanian children (boys,  $n = 20$ ; girls,  $n = 20$ ) with mean age  $11 \pm 0.47$ , was divided into an 'overweight' and 'non-overweight' based on body mass index, lower limb power was assessed by ergo jump in Squat Jump (SJ) and counter movement jump (CMJ). In 'non-overweight children (G1;  $n=23$ ) BMI between 18.5 kg.m<sup>-2</sup> and 20 kg.m<sup>-2</sup>; and in 'overweight' (G2;  $n=17$ ) BMI was between 24.5 kg.m<sup>-2</sup> and 26.5 kg.m<sup>-2</sup>. **Results** Overweight girls had inferior performances on both tests (SJ 18.07 cm (SD 3.07) and CMJ 20.43 (SD 3.30) compared with non-overweight counterparts (SJ 22.17 (SD 2.57), CMJ 25.6 (SD 4.76) ( $p < 0.001$ ). The overweight active boys had greater power than overweight non active girls, statistically no significant, but smaller than non-overweight girls. Overweight boys had lower values on SJ (20.54 cm (SD 4.19) and CMJ 22.83 cm (SD 4.51) compared with non-overweight (SJ 24.23 (SD 1.80) and CMJ 27.28 (SD 0.94)  $P < 0.01$ . Fat was calculated with the perimeters formula (4) in normal weight boys (22.76%) and girls (21.08%) and lean body mass in overweight boys (40.97 kg) and girls (35.92 kg). **Discussion** The possibility exists, that overweight children may be affected by their weight during explosive movements involving the lower limb muscles groups. Results suggest that predominant factor in jumping ability in this age is bodyweight. Low power limb level of overweight boys and girls can be explained with their adiposity and lack of muscle mass, and this is a factor why their parents engage them in some form of physical activity. The parents of non-overweight children do not care for inactivity of their children, until they are not overweight. **References** 1. Trost S, Kerr L, Ward D, Pate R. ### EXERCISE FOR HEALTH AND PHYSICAL PERFORMANCE IN CHILDREN OF AGE 15 YEARS OLD IN TIRANA

MARTIRI, A.1, MEMA, F.1, QELESHI, A.1

ACADEMY OF PHYSICAL EDUCATION AND SPORT

**Exercise for Health and physical Performance in children of age 15 years old in Tirana** Martiri, A.1, Mema, F.1, Qeleshi, A.1, 1: UNIVERSITY OF SPORT OF TIRANA **Introduction:** A number of strategies have shown promise for increasing physical active lifestyle. Studies have show that the incorporation of multiple (2-4) short bouts of exercise (10 -15 minutes in length) performed each day can significantly improve cardio respiratory fitness ( DeBusk, R.F., et. al 1990, Jakicic et. Al 1995,) **Objectives:** To objectively investigate the problem of engage in exercise for health .... **Subjects:** This study engages 300 children-boys and girls 15 years old in public (" Jeronim de rada") and non public ("Reze

Drite" ) school . Methodology: questionnaire assessment Exercise for health and performance has been applied. (Poul M.Insel and Walton T.Roth 1988). Results: Data from questionnaire show: In Private School at moderate level in scale 32 % (boys 13 % girls 29%), at superior level 30 % boys 15 % girls 15%), and optimal level 23 % boys 22 girls 1% ). In Public School at moderate level in scale 28 % (boys 10 % girls 18%), at superior level 53 % (boys 32 % girls 21%) and optimal level 14 % (boys 9 % girls 5%). Discussion: This modest study show a significant data that children 15 years old engages in exercise for health .We expected from this study more positive value but anyway in superior level (where the participation here is often engages in regular exercise ) we find promise data, plus in optimal level (where a person at this level enjoys a regular exercise program) data low value ,but better for children in private school. These two school are in the middle of capital and as we see the situation speak themselves. References- 1 DeBusk, R.F., U. Stenestrand, M. Sheehan and W.L.Haskell.1990. ## 6 MINUTE ENDURANCE RUN TO DETERMINE ENDURANCE CAPACITY: A QUESTION OF MOTIVATION?

KOCH, B.1, KOBEL, S.1, WEBER, S.1, BRANDSTETTER, S.1, DREYHAUPT, J.2, WIEDOM, M.2, MUCHE, R.2, STEINACKER, J.M.1  
ULM UNIVERSITY

**Introduction** Aerobic endurance performance has an important role with regards to the prevention of cardiovascular risk factors. To determine endurance capacity in childhood and adolescence the 6 minute endurance run is currently used in many sports performance profiles (Tomkinson & Olds, 2007). In this study, it was examined whether children's motivation is sufficiently pronounced to complete the test. Motivation is operationalized by using an objective parameter (course of heart rate). **Methods** 45 children (age:  $7.5 \pm 0.6$  years; bmi:  $16.4 \pm 2.8$ ; 15.6% overweight; 60% boys) performed a 6 min endurance run in the sports hall (Graf et al., 2004). Heart rate (HR) was assessed using Actiheart®. Mean HR was calculated in beat-per-minutes (bpm) for each one-minute period. Data of second to sixth period were analysed with repeated measures ANOVA. **Results** During the 6 min run boys showed significantly better performance than girls ( $914 \pm 189$  m vs  $805 \pm 106$  m;  $p=0.017$ ). Mean HR in boys was  $189 \pm 12$  bpm (maximum HR:  $204 \pm 8$  bpm), in girls  $184 \pm 16$  bpm (maximum HR:  $199 \pm 13$  bpm; all n.s.). Regarding the course of HR, repeated measures ANOVA did not show a significant time effect on mean HR from second to sixth period. This suggests that mean HR stays on a high level over the course of all time periods of the test. Neither sex nor overweight status did influence the above. **Discussion** By using the objective parameter course of HR, a high level of motivation throughout the entire period of the 6-minute run was documented in all children, regardless of gender, age and overweight status. Thus, the 6 min run proved to be a valid instrument to assess endurance capacity, even in younger children and those without any running experience. **References** Tomkinson GR, Olds TS. Secular changes in pediatric aerobic fitness test performance: the global picture. In: Tomkinson GR, Olds TS (Hrsg.). *Pediatric fitness – secular trends and geographic variability*. Med Sport Sci. ## ENERGY EXPENDITURE IN CHILDREN DURING TREADMILL LOCOMOTION ASSESSED BY ACTIHEART® AND INDIRECT CALORIMETRY

KOBEL, S., KOCH, B., WEBER, S., BRANDSTETTER, S., TREFF, G., STEINACKER, J.  
ULM UNIVERSITY

**Background** Accurate measurement of physical activity in children is still a challenge. Combining heart rate (HR) and accelerometry may overcome limitations with either method used on its own (Brage et al, 2005). This study therefore aimed to compare the estimated energy expenditure (EE) from the combined HR and movement sensor Actiheart® with the gold standard indirect calorimetry during treadmill locomotion in primary school children. **Methods** Resting energy expenditure (REE) and submaximal EE (treadmill walking and running, 5 phases, 2-8 km/h) were measured in 15 children ( $9.2 \pm 1.5$  yr; 9 girls; BMI  $16.14 \pm 1.35$ ; recruited from the local sports club) by indirect calorimetry (Cortex Metamax 3, Germany) during a progressive treadmill exercise bout whilst wearing two Actiheart® (CamNtech, Cambridge, UK) - one at level with the third intercostal space and one just below the apex of the sternum. Using the Branched Model of Actiheart®'s software ("Child: GroupHR/GroupAct") to calculate total EE (TEE) METs were calculated and compared with the oxygen uptake generated by indirect calorimetry. **Results** METs increased linearly with each treadmill stage for activity sensor and indirect calorimetry (Actiheart®  $y=2.54+1.40 \cdot x$ ; indirect calorimetry  $y=2.40+1.89 \cdot x$ ). However, the correlations between Actiheart® and indirect calorimetry were non-significant and vary per stage between -.133 and .120. Overall, TEE measured by Actiheart® underestimates the values measured by indirect calorimetry ( $6.72 \pm 2.33$  METs and  $8.03 \pm 3.07$  METs, respectively) over all treadmill phases by 9.75% ( $\pm 23.05$ ). No placement effect was found on movement counts for either treadmill phase and speed, nor was there a significant placement effect on HR data during the first 4 treadmill phases. **Conclusion** Physical activity EE underestimation at vigorous intensities has been reported previously (Corder et al, 2005). This study however, shows Actiheart® consistently underestimates TEE in primary school children throughout all treadmill phases compared with indirect calorimetry. Placement can be disregarded as limiting factor since recordings of both Actiheart® correlated significantly with each other in HR data and movement counts. **References** Brage, S. et al (2006). #### EXPERT YOUTH COACHES' CONCEPTS OF STRENGTH TRAINING IN LONG TERM ATHLETE DEVELOPMENT

VOIGT, L., SINGH, A., HOHMANN, A.  
UNIVERSITY OF BAYREUTH

**Introduction** Necessary performance improvements in competitive sports cannot be achieved exclusively through the optimization of high performance training in the adult stage but require a long-term performance build up process (Rost, 2002). Therefore, systematic strength training should begin in the junior age segment and aim at both prevention and performance enhancing targets (Carl and Horn, 2008).

What appears to remain unaddressed is the question of how to correctly apply strength training in youth sports in the process of long term training. The purpose of this study was to analyze expert youth sports coaches' understanding of their incorporated practice of strength training and to identify basic principles for long term athlete development. Methods Following a qualitative research methodology, data were collected from qualitative, semi-structured interviews. An interview guide was developed to allow for the optimal comparability of the data and to ensure that each interview addressed the required topics. Data were analyzed by using coding procedures and inductive categorization methods inspired by grounded theory principles (Glaser and Strauss, 1967) in order to identify core categories and themes (case study approach). Fifteen expert youth-coaches ( $n = 15$ ) participated in this part of the study reported here. The coaches were classified as expert coaches based on specified criteria related to multiple success in coaching. Specifically, expert coaches were defined by the number of successfully coached athletes who reached international competitions in the sport-specific high performance age. Results The evaluation of the data focused on reconstructing strategies for a long term design of strength training. Analysis of the transcribed interviews led to three cross-case-concepts that fulfilled the function of a "conditio sine qua non" related to top sports performance in the adult stage: "health-prevention", "presupposition for optimal technique", "presupposition for specific training methods and exercises". All concepts can be summarized under the higher order concept "presupposition-training", which is embedded in a basic training philosophy that focuses strictly on sports specific success in the peak performance age. ## EFFECT OF GENDER ON MOTIVATIONS AND CONCERNS OF ONLINE SPORT CONSUMERS

ALTUN, M., ALAY, S., KARAKILIC, M.

METU., GAZIUNIV., KCU.

INTRODUCTION: In considering the growth of online sport business, it is important for sport marketers and managers to understand the opportunities, limitations and consumers' need presented by online sport marketing (Rein, Kotler & Shields, 2007). To fully realize the business opportunities of the Internet, sport marketers need to develop better understanding for online sport consumers and their behavior (Hur, Ko & Valacich, 2007). Therefore, the purpose of this study was to investigate the effect of gender on motivations and concerns of online sport consumers. METHOD: 1154 online sport consumer from a shopping website were participated in this study (896 male, 258 female). Data were collected by the Scale of Motivation and Concern for Online Sport Consumption (SMCOSC) (Altun, 2011) to identify the online shopping motivations and concerns of online sport consumers. The motivation scale has 45 items with 5 subscales (diversion, information, economic motive, socialization and convenience). The concern scale has 27 items with 5 subscales (security-privacy, product quality, customer services, delivery and cost). Internal consistency reliabilities of the each of the scales were .96. Participants who bought only sport products filled out the scale through the internet. Two 2x5 (respondent's gender x shopping motives and respondent's gender x shopping concerns) MANOVA was conducted to examine the effect of gender on motivations and concerns of online sport consumers. RESULTS: MANOVA results showed that there were a significant difference in the online sport consumers' motivation scores of SMCOSC subscales in terms of gender [Wilks's  $\Lambda(4) = 0.960, F(5-1148) = 9.637, p < .01$ ]. Follow up ANOVA results showed that there were a significant mean difference between convenience [ $F(1-1152) = 4.366, p < .05$ ] and socialization [ $F(1-1152) = 31.489, p < .01$ ] subscale scores of online sport consumers in terms of gender. As the convenience motive of women is higher than that of men, socialization motive of men is higher than that of women. MANOVA results showed that there were a significant difference in the online sport consumers' concern scores of SMCOSC subscales in terms of gender [Wilks's  $\Lambda(4) = 0.974, F(5-1148) = 6133, p < .01$ ]. Follow up ANOVA results showed that there were significant mean difference between security-privacy [ $F(1-1152) = 11634, p < .01$ ] and delivery [ $F(1-1152) = 21.721, p < .01$ ] subscale scores of online sport consumers in terms of gender. The concern of men on security-privacy and delivery is higher than that of women. DISCUSSION: It might be concluded that gender is a distinguishing factor for online sport consumers' motivations and concerns on their online shopping. REFERENCES: Hur, Y., Ko, Y.J., Valacich, J. ## PERCEIVED RELATIVE SPORT-SPECIFIC PHYSICAL FITNESS RELATES TO MENTAL TOUGHNESS IN ELITE MALE HANDBALL PLAYERS.

RODAHL, S.1, PETERS, D.M.2,3, HØIGAARD, R.3

1: UII (NORDLAND, NORWAY), 2: UW (WORCESTER, UK), 3: UIA (KRISTIANSAND, NORWAY)

Introduction Mental toughness (MT) in a sporting context has been defined as 'the ability to consistently perform toward the upper range of your talent and skills regardless of competitive circumstances' (Loehr, 1994, p. 5) and a high level of MT has been proposed as a critical attribute for elite level performance (Sheard, 2010). Sport-related MT is undoubtedly borne from interactions between life experience and those experiences specific to sport. In contact team sports at a high competitive level such as elite handball which has high demands on strength and power (Gorostiga et al., 2006), it is reasonable to suggest that an individual's level of MT could not be achieved in isolation and without comparison to their peers with whom they have to compete for position, and even more-so in comparison with their opponents who they have to defeat in order to succeed. The purpose of this study was to investigate the relationship between perceived relative levels of sport-specific physical fitness and MT in elite male handball players. Methods Forty eight handball players from the premier league and first division in Norway (mean age  $20.7 \pm 5$  years) responded to questions asking them to rate their level of strength, speed & endurance relative to the other players in the league on a scale of 1 (amongst the worst) to 10 (amongst the best) and completed the 43-item Mental (M,  $\alpha = .85$ ), Emotional (E,  $\alpha = .82$ ), and Bodily (B,  $\alpha = .62$ ) Toughness Inventory (MeBTough, Mack & Ragan, 2008). Results Significant correlations were apparent between perceived relative endurance and B ( $\rho = .44$ ), E ( $\rho = .36$ ) & M ( $\rho = .29$ ); between perceived relative speed and B ( $\rho = .35$ ) & E ( $\rho = .33$ ); and between perceived relative strength and B ( $\rho = .47$ ). Discussion Whilst higher perceived relative strength, endurance & speed were all related to greater levels of bodily mental toughness, a scale that most reflects the physicality of sport, relative endurance would appear to be the one factor related to all aspects of mental toughness in handball. Further evaluation of the MeBTough inventory is required and future research should investigate the impact on Mental Toughness of improvement in both actual and perceived sport-specific physical fitness. ## THE RELATIONSHIP BETWEEN SPORTS ALEXITHYMIA, SOCIO-DEMOGRAPHIC VARIABLES AND ATHLETES BURN-OUT

AMEMIYA, R.1, SHIMIZU, Y.2, MIYAZAKI, M.2

1: COLLEGE OF LIBERAL ARTS, J.F. OBERLINE UNIVERSITY, JAPAN 2: COLLEGE OF HEALTH AND WELFARE, J.F. OBERLINE UNIVERSITY, JAPAN

**Introduction** Prior studies have shown that alexithymia is a personality trait that is associated with the difficulty in identifying and describing feelings and externally oriented thinking. Present studies of alexithymia have been widely expanded into other areas of psychology such as clinical psychology. However, past studies of alexithymia have not investigated it in the sports psychology area. Initial studies showed a common result that alexithymia was clearly associated with burn-out, indicating that the alexithymic characteristic might be one of the risk factors in athlete burn-out. The purpose of this study was to develop a new alexithymia scale for Japanese university athletes, and investigate the relationship between alexithymia and burn-out among university athletes. **Methods** Participants in this study were 259 university athletes (males=102, females=157, mean age=19.8, SD=1.1). They were given a questionnaire divided by socio-demographic variables, 20 alexithymia question items that edited Gotow alexithymia Scale in athletes, 28 burn-out question items in athletes from October to December 2010. In order to develop the Sports Alexithymia Scale(SAS) and Burn-Out Scale for Athletes(BOSA), exploratory factor analyses was conducted and to examine the statistical differences in socio-demographic variables, t-tests and one way ANOVA were conducted to the mean scores of SAS and BOSA. Multiple regression analyses were conducted to show the relationships between SAS and BOSA. **Results** The results of exploratory factor analysis revealed a 3 factor model in SAS and a 4 factor model in BOSA. Confirmatory factor analyses and reliability analyses confirmed the structural validities and factor reliabilities. The results of the analyses showed that the mean score of SAS and BOSA factors were significantly different among gender, grades and type of team, and the factors of SAS were significantly associated with the factors of BOSA. **Discussion** The results showed that high alexithymic individuals prefer to participate in individual competition sports. Alexithymic individuals prefer an environment where it is not imperative to have a personal support system. The results of one-way ANOVA showed that freshman sophomore and juniors have higher alexithymia than senior students, indicating that belonging to a sports team over a long term has positive effects on athletes' personality. The results of multiple regression analysis indicated that alexithymia is one of the risk factors for the burn-out state in athletes. The alexithymia trait in athletes needs to be examined on this scale more in future research. **Reference** 1)Gotow Kazufumi, Kodama Masahiro, Sasaki Yuji 1991. Is alexithymia unidimensional? ## DEVELOPMENT OF PHYSICAL AND SOCIO-PSYCHOLOGICAL STRESSORS SCALE FOR UNIVERSITY ATHLETES

UENO, Y.1, SHIMIZU, Y.2, MIYAZAKI, M.2

1: GRADUATE SCHOOL OF PSYCHOLOGY, J.F. OBERLIN UNIVERSITY, JAPAN, 2: COLLEGE OF HEALTH AND WELFARE, J.F. OBERLIN UNIVERSITY, JAPAN

**Introduction** Although numerous studies have demonstrated a relationship between stressful life events and the occurrence of physical and psychological disorder, little attention has been given to examining the association between life stress and athletic stress. The purpose of this study was to develop Physical and Socio-Psychological Stressors Scale for University Athletes (PSPSSUA) and to examine the relationship between Stressor variables of PSPSSUA and socio-demographic variables, stress response variables. **Methods** The subjects of 390 university students (male=193, female=197; mean age=19.70, SD=1.18) were asked to answer a questionnaire that was composed of socio-demographic questions, 70 stressor question items that were acquired from our preliminary survey in June, 2010 and Stress Response Scale for High School Athletes (SRSHSA) that were made of 32 question items developed by Shibukura (1999). Step-wise exploratory factor analyses, confirmatory factor analyses and reliability analyses were conducted to develop the PSPSSUA. In order to examine the socio-demographic differences, t-test and one-way ANOVA were conducted to PSPSSUA and SRSHSA. Step-wise multiple regression analyses were conducted to examine the correlation between PSPSSUA and SRSHSA. **Results** The results of step-wise exploratory factor analyses identified a ten-factor model with 40 items on PSPSSUA. Confirmatory factor analyses and reliability analyses confirmed that the scale had satisfactory fit indices of structural validities and Cronbach's alpha coefficient reliabilities. The results of t-test showed that the mean scores of some PSPSSUA factors were significantly different between male and female athletes. The result of one-way ANOVA found that sophomore athletes showed statistically higher scores than freshmen athletes on several PSPSSUA factors. The results of step-wise multiple regression analyses that were set PSPSSUA as independent variables and SRSHSA as dependent variables showed that the sub-scales of PSPSSUA were significantly associated with the sub-scales of SRSHSA. **Discussion** The results of t-test and one-way ANOVA indicated that there are differences in stressor cognition level between male and female and among athletes' grades. The results of step-wise multiple regression analyses implies that stress management programs and mental training programs for psychological relaxation can be beneficial to reducing athletes' stress level. Further studies with longitudinal design will be needed to examine effective psychological intervention methods. **References** Lazarus, R. S., and Folkman, S. (1984) Stress, appraisal and coping. ## COMPETITIVE ANXIETY IN ATHLETES AGED 15 AND 16.

CUKA, A.

UNIVERSITY OF SPORT TIRANA

1. Cuka, A. 2. Zhurda, Y. 1: UST (Tirana, Albania), 2: UST (Tirana, Albania) **Introduction** Anxiety in athletes originates from early age. Competitive sport imposes high levels of anxiety at youngsters. Anxiety, being a part of competitive experiences, must be managed by athletes in order to help their performance. Thus, the aim of this study is to investigate on the level of competitive anxiety at youngsters, so that it can be recognized and managed for a better performance. **Methods** Subjects of this study are 218 youngsters aged 15 and 16 (48 females). They practise team and individual sports. The instrument used is the Sport Competition Anxiety Test, SCAT by Martens, Vealey and Burton, 1990. The data gathered by the questionnaire are processed by SPSS, 15.0 version, program. The reliability analyses and alpha method are also used. **Results** 8.71% of the subjects are characterized by a high level of competitive anxiety, 58.26% are at an average level and 33.03% at a low level. Alpha Chronbach 0.875. Athletes who practise individual sports indicate higher level of competitive anxiety both for the highest grade. i.e. 8.51% of them vs. 8 % of team sports players, and at average grade 61.75% vs. 56.52% of subject who practise team sports. **Discussion** The subjects are characterized by different levels of competitive anxiety trait, both in total number as well as according to types of sport and gender. More than half of the subjects are characterized by an average level of anxiety, only a low percentage are characterized by a high level of anxiety. Athlete's performance, depending on interactive processes and

situations, is affected by their anxiety. Being able to face pressure and anxiety is an integral part of sport. (Hardy, Jones & Gould 1996). Differences between males and females are noticed. Girls reflect higher indicators of the anxiety at average and high level, yet the percentage of girls with a low level of anxiety is equal to the half of that of boys. The reliability shown by Alpha = 0.875. The study identifies differences according to type of sport, i.e. a team vs. individual sports. Athletes of individual sports show higher anxiety levels compared to those of team sports. Alfa Chronbach 0.875. This corresponds with the studies of Weinberg (2007) that states that "children playing individual sports experience greater anxiety than those playing team sport". Competitive anxiety indicators are reflected in youngsters competitive activities. A considerable percentage of the subjects experience preoccupation, worry about their performance both before and during competition, only 22% do not feel worried. References Hardy, L., Jones, G., & Gould, D. (1996). *Understanding Psychological Preparation for Sport: Theory and Practice of Elite Performers*. Wiley, Chichester. Weinberg, R.S. & Gould, D. (2007). *Foundations of sport and exercise psychology*. (4th ed.). Champaign, IL: Human Kinetics.

### **RELATIONSHIP BETWEEN INJURY, PAIN AND PERSONALITY IN ATHLETES.**

RABELO, I., GODOY MOREIRA, F., RUBIO, K.

UNIVERSITY OF SÃO PAULO

**Objective** This study aims to examine how athletes perceive, live with and manage pain episodes, and sensitivity in responding to the signs and limits, which are essential in the search for better results. Aiming to analyze the relationship between injury, pain and personality traits in athletes was used Pain Inventory for Sport (SIP) which is an instrument that measures five sub-scales, being direct confrontation (COP), cognitive (COG) catastrophizing (CAT), avoidance (AVD) and body awareness (BOD) and Total Coping Response (TCR = COP + COG - CAT) an overall indicator of the ability of athletes to play their role to experience physical injury or painful conditions. Another instrument used was the Neuroticism Scale Factor (EFN), a sub-scale Factor Personality Battery (BFP), based on the Five Factor Model (CGF). The EFN is composed of sub-factors Vulnerability (N1), emotional instability (N2), Passivity / Lack of Energy (N3) and depression (N4). **Method** The study included 11 athletes, 81.8% male, aged between 22 and 42 years ( $M = 28.91$ ,  $SD = 5.97$ ) who had evidence of Multiathlon 2009. Of these three (27.3%) had some type of injury, 4 (36.4%) were not injured but had had some type of recent injury and other 4 (36.4%) had no injury. **Discussion** The data indicated that the instruments have proven reliable in this sample, with accuracy rates by means of Cronbach's alpha of 0.96 for the EFN and 0.72 for the SIP. There was no difference in relation to gender in both instruments, although the averages are higher for women, but only in relation to BOD factor is the gender difference was significant in Student's *t* test, which can demonstrate a lower body awareness in women. However, it is noteworthy that this difference may relate to the number of female subjects in the sample that was less than masculine. Regarding the age variable, there were no differences between the factors of the instruments by means of ANOVA, however there was significant negative correlation between age and vulnerability, passivity / lack of energy and total neuroticism, which allows us to infer that the extent in advancing age, show lower percentiles on these factors. **Conclusion.** It is noteworthy in the scale of Neuroticism that the athletes had median ratings (36.4%) and very low (45.5%) in vulnerability, low results (36.4%) and very low (27.3%) in Instability Emotional ratings medians (27.3%) and very low (45.5%) in Passivity / Lack of Energy and average results (45.5%), low (18.2%) and very low (18.2%) in Depression. Regarding the overall classification of Neuroticism also focused on low (27.3%) and very low (36.4%). Finally significance was found regarding the variable lesion only in relation to variable CAT, which was significant in Student's *t* test, allowing to infer that injured athletes who never had a higher average score at the facet catastrophizing. There is, however, nearly significant negative correlations between moderate injury and N1, N2 and N4.

### **SELF CONFIDENCE PERFORMANCE RELATIONSHIP: THE MEDIATING ROLE OF COPING**

LEVY, A., NICHOLLS, A., POLMAN, R.

EDGE HILL UNIVERSITY

**SELF CONFIDENCE- PERFORMANCE RELATIONSHIP: THE MEDIATING ROLE OF COPING** Levy, A.1, Nicholls, R.2, Polman, R.3 1: Edge Hill University (UK), 2: University of Hull (UK), 3: Victoria University (Australia) **Introduction** To achieve sporting excellence it is generally believed that athletes need to possess a high degree of self-confidence. However, the mechanisms which account for the self-confidence performance relationship is unclear. An important starting point when considering potential mechanisms is to identify pertinent mediator variables. A potential construct that may mediate the confidence-performance relationship is coping. Therefore, this study aimed to elucidate whether coping acted as a mediating influence. **Methods** Four hundred and fourteen athletic performers (222 male, 192 female, mean  $\pm$  SD; age  $21.63 \pm 6.45$  yr) took part in this study. The State Sport Confidence Inventory (SSCI; Vealey, 1986) measured confidence among the athletes. To assess coping, Gaudreau and Blondin's (2002) Coping Inventory for Competitive Sport (CICS) was adopted. Following competition, participants subjectively rated their performance satisfaction. Participants completed the SSSI prospectively, one hour before their competitive event started. The CICS and subjective performance were measured retrospectively, one hour following competition. **The multiple mediation analysis with bootstrapping** conducted in the present study was preferred above the causal step strategy. **Results** The mediation analysis for coping at the dimensional level revealed that task (BCa 95% CI 0.0028-0.0093) and disengagement-orientated coping (BCa 95% CI 0.0010-0.0063) partially mediated the effect of sport confidence on subjective performance. The mediation analysis for coping at the strategy level revealed that mental imagery (BCa 95% CI 0.0060-0.0165) and resignation (BCa 95% CI 0.0055-0.0144) coping partially mediated the effect of sport confidence on subjective performance. **Discussion** Findings revealed that task-orientated coping was a positive partial mediator, whereas disengagement-orientated coping was a partial negative mediator of the confidence-performance relationship. Of the 10 different coping strategies assessed, only mental imagery (task-orientated coping) and resignation (disengagement-orientated coping) had partial mediating effects. Importantly, task-orientated coping may act as an effective mechanism in which to improve confidence and performance. To achieve this, sport psychologists need to ensure that athletes appropriately use mental imagery. Additionally, sport psychologists need to ensure athletes avoid the use of disengagement coping strategies such as resignation. Doing so may negate the debilitating effect low confidence has on performance. **References** Vealey R. (1986). *J Sport Psychol*, 8, 221-246. Gaudreau P, Blondin JP. (2002). *Psych Sport Exerc*, 3, 1-34.

### **MENTAL SKILLS IN SOUTH AFRICAN AND UK UNIVERSITY STUDENTS**

BUSCOMBE, R., EDWARDS, D.J., STEYN, B.J.M.

UNIVERSITY OF EAST LONDON, UNIVERSITY OF ZULULAND, UNIVERSITY OF PRETORIA

**Introduction** Whilst mental skills are both holistic and naturally occurring such skills can be trained for specific settings such as sport and exercise to improve performance outcomes and enhance an athlete's psychological well-being. Mental skills are often measured indivi-

dually and/or collectively using internationally developed scales. This study was conducted with three primary aims: 1) to acquire preliminary norms for Bull's Mental Skills Questionnaire employing an International sample, 2) draw comparisons across subscale means derived from UK and South African groups, 3) to investigate relationships between subscales on the inventory. Methods Data were collected from 500 South African and 209 UK male and female, university students ( $M=20.18$ ;  $SD=2.61$  and  $M=22.17$ ;  $SD=5.20$ , respectively). Participants were administered Bull's Mental Skills Questionnaire (Bull, 1991) which consists of seven mental skill subscales: imagery ability (ia), mental preparation (mp), self-confidence (sc), anxiety and worry management (awm), concentration ability (ca), relaxation ability (ra) and motivation (m). Results Means and standard deviations for the subscales and total score were as follows (South Africa : UK, respectively): ia (18.55; 3.46: 18.57; 3.36), mp (18.55; 3.73: 17.31; 3.75), sc (17.48; 4.10: 16.38; 3.75), awm (15.32; 4.99: 15.78; 2.89), ca (17.96; 4.45: 18.23; 4.58), ra (16.27; 4.59: 15.58; 2.89), m (19.07; 3.64: 19.46; 3.33) and total (123.22; 18.79: 121.30; 17.51). In the South African sample significant correlations emerged between all subscales except between imagery ability and anxiety and worry management. The UK sample evidenced significant correlations between all subscales ( $p<0.05$ ). Discussion Preliminary norms were established and were shown to be similar across the UK and South African samples. The results indicated a high level of correlation amongst subscales in both groups. Future work is planned to expand the study to include additional International samples and to investigate further the relationship between mental skills and psychological well-being in athletes. ## ACADEMIC AND ATHLETIC MOTIVATION OF ITALIAN STUDENT-ATHLETES

GUIDOTTI, F.1, MINGANTI, C.1,2, CORTIS, C.1, PIACENTINI, M.F.1, TESSITORE, A.1, CAPRANICA, L.1.

1: DISMUS, UNIVERSITY FORO ITALICO (ROME, ITALY), 2: DEPARTMENT OF CLINICAL AND EXPERIMENTAL MEDICINE, UNIVERSITY MAGNA GRAECIA (CATANZARO, ITALY)

Introduction Academic institutions are interested in predicting the rate at which athletes make progress toward degree completion in college (Gaston-Gayles, 2005). Although academic and athletic motivations have been studied as predictors of academic success in American student-athletes (Simons et al., 1999), no data are available for European ones. Thus, the aim of the present study was to validate the Italian version of the Student Athletes' Motivation toward Sports and Academics Questionnaire (SAMSAQ; Gaston-Gayles, 2005). Methods Italian student-athletes ( $n=323$ ; age:  $19.4\pm 3.1$  yrs; 48.3% high school; 51.7% college) participated in this study. Participant's competition level accounted for: 23.2%, 49.8%, and 26.9% for provincial, regional, and national levels, respectively. The 30-item SAMSAQ was administered to verify the applicability of the three-factors model (Academic Motivation, AM; Student Athletic Motivation, SAM; Career Athletic Motivation, CAM) in Italy. Exploratory Factor Analysis (EFA; Oblique Rotation; Maximum Likelihood) and reliability estimates (Cronbach's alpha) were conducted to evaluate the factor structure and the internal consistency of the items on each subscale, respectively. For each subscale, differences ( $p<0.05$ ) for gender (male vs female), education level (high school vs college), and competition level (provincial vs regional vs national) were calculated. Results A strong two-factors model emerged, with acceptable Cronbach's alpha coefficients only for SAM (0.86) and AM (0.78). Factor structure loaded 12-items for SAM and 12-items for AM, whereas 7 items seemed to be unrelated both with SAM and AM. Regarding SAM, provincial level showed significant lower value with respect to both national ( $p=0.0029$ ) and regional ( $p=0.0154$ ) levels. Furthermore, college student-athletes showed a higher ( $p<0.0001$ ) AM with respect to high school counterparts. Discussion To our knowledge, this study is the first attempt to evaluate the academic and athletic motivation in Italian student-athletes. For Italian student-athletes, a two-factor (i.e., AM and SAM) model emerged instead of three, according to the literature (Willis, 2005). Considering that in the United States sport is organized within educational institutions and in Italy the two systems are separated, some items have to be reformulated. Further studies are needed to confirm the factorial structure of SAMSAQ, enlarging the sample under investigation. References Gaston-Gayles J. (2005). J College Student Develop, 46(3), 317-327. ## ATTITUDE TOWARDS PERFORMANCE-ENHANCING DRUGS IN SPANISH ROAD CYCLING NATIONAL TEAMS

MORENTE-SÁNCHEZ, J., FREIRE, C., FEMIA-MARZO, P., SÁNCHEZ-MUÑOZ, C., ZABALA, M.

FACULTY OF PHYSICAL ACTIVITY AND SPORT SCIENCES, UNIVERSITY OF GRANADA (SPAIN)

Introduction Doping has stained the world of competitive sport in the last years, especially in sports like Cycling and Athletics. To alleviate and mitigate this problem it has become necessary the roll of prevention working around attitudes towards doping at different levels (1), defending the education and formation at the earliest ages (2). The aim of the present study was to know and compare the attitudes towards performance-enhancing drugs (PED) in the cyclists that form the Spanish National road cycling teams. Methods A sample of 34 cyclists of the Spanish national teams (Junior men -J-, Under-23 men -U23-, Junior Women -JW-, and Elite Women -EW- categories) took part in the study that was divided into groups according to the competing category (9 J, 9 U23, 10 JW, and 6 EW). The subjects were taking part in an official training camp in Segovia (Spain) in January 2011. Descriptive design was carried out by means of a validated questionnaire (1) of 17 questions using a Likert scale from 1 (Strongly Disagree) to 6 (Strongly Agree) for different statements that supported the use of PED in sport. Mean value  $\pm$  Standard Deviation was obtained for each item and Mann Whitney test for independent variables with Bonferroni post hoc was carried out. Results In general, the score for the mean of all the items was  $2.06\pm 0.39$  (2=Through Disagree). The lowest score was observed for the item "Doping is not cheating since everyone does it" with  $1.09\pm 0.38$ , and the highest for "The media blows the doping issue out of proportion" with  $4.53\pm 1.48$  (4=Slightly Agree; 5=Agree). Just for two items ("The risks related to doping are exaggerated" and "There is no difference between drugs, fiberglass poles, and speedy swimsuits that are all used to enhance performance") significant differences were observed between J (3.00) and the other groups U23 (1.22), JW (2.40), and EW (1.17) -  $p=0.000$ -, and between J (2.22) and the other groups U23 (1.00), JW (1.10), and EW (2.00) -  $p=0.001$ -, for the two items respectively. For the rest items no significant differences between groups were observed. Discussion Results of the present study show that road cyclists of the Spanish national teams are not permissive with PED. Just the younger cyclists (J) are a bit less contrary towards the use of PED than the rest of the groups but in two items. This empowers the idea that information and education is needed since the earliest ages and psychosocial intervention programs are needed to educate cyclists as well as all the people around them. **THE EMOTIONAL INTELLIGENCE SPORTS INVENTORY : A PRELIMINARY CROSS CULTURAL ANALYSIS**

SAUNDERS, J.

AUSTRALIAN CATHOLIC UNIVERSITY

THE EMOTIONAL INTELLIGENCE SPORTS INVENTORY (ESI): A PRELIMINARY CROSS CULTURAL ANALYSIS Saunders, J. 1, Smith, K.1, Newman, M. 2, Rawlins, J. 3 1: Australian Catholic University (Melbourne, Aus), 2: RocheMartin Australia, 3: University College of Wales in Cardiff

**Introduction** The Emotional Intelligence Sports Inventory (ESI) (Newman, 2010) has been identified as a useful consultant instrument for work with elite international sportsmen and been used in the field for several years, with high degrees of client satisfaction being reported. It is based on a theoretically derived ten factor model of emotional intelligence related skills. There has however been no reported empirical validation of the instrument and this study represents part of an initial attempt to review its efficacy for sport related populations across a range of cultural settings

**Methods** A paper and pencil version of the ESI was administered under classroom conditions to undergraduate students in exercise and sport degree programs in Australia (N=93), and in Wales (N= 279). The instrument comprised 77 randomised positively and negatively worded items requiring a Likert type response on a five point. Some additional questions provided information about the respondents their levels of sport involvement and personal sporting history. All analyses were conducted using PASW Statistics Version 18 (SPSS, 2009) and EQS Version 6.1 (EQS, 2006)

**Results** For the purpose of this analysis the Welsh sample was broken down into those who had been brought up in Wales (134) and those who had come to the university from England (145). In terms of level of participation, around one third was competing at a national or international level in their sport. The Australian sample had a slightly higher proportion of casual/social participants than their English/Welsh counterparts. Preliminary analyses indicate few differences between the three national groups but greater differences between males and females on a number of subscales.

**Discussion** This initial analysis revealed that this ten factor construct of emotional sports intelligence may have some promise as a tool for discriminating between elements of mental approaches to sports performance. However more work is needed in refining the instrument and its scales if it is to be robust enough for use in a variety of cultural contexts. There were some differences in the reliability of the individual scales between the groups and this may reflect either simple semantic differences or more important underlying cultural frameworks. Further development of the instrument validated within a broader range of cultural frameworks is currently in process

**Poster presentations****PP-SH13 Psychology: Mental Skills****THE INFLUENCES OF ANXIETY AND CONFIDENCE ON IMAGERY CONTENT AND PERCEIVED FUNCTION**

NEWELL, E., COYLE, M.

LOUGHBOROUGH COLLEGE, UNIVERISTY COLLEGE PLYMOUTH

**Introduction** A body of research has demonstrated that athletes use a range of image types to fulfil a range of functions. Callow & Hardy (2001) have suggested that it may not be what is being imagined (image content) that is critical to image outcome, rather the function of what is being imagined i.e. why the athlete is using that image. Present knowledge of the factors that influence an athlete's perception of the function of imagery is limited. Bernier and Fournier (2010) comment that the situation (including the psychological state) in which imagery occurs is likely to influence image content. The purpose of the present study is to examine the influence of confidence and anxiety on image content (the 'what') and perceived functions of that image content (the 'why').

**Methods** Participants are 121 male, semi-professional footballers from 7 teams competing in the League of Wales Premier Division. Participants were placed into one of four possible groups according to data collected using the Competitive Trait Anxiety Inventory (CTAI-2; Jones & Swain, 1992). The groups were High Confident/High Anxious, High Confident/Low Anxious, Low Confident/High Anxious, and Low Confident/Low Anxious. Data relating to image content and perceived image function was collated via a revised version of the Sport Imagery Questionnaire (SIQ-R; Short, Monsma & Short, 2004).

**Results** A profile analysis revealed a significant group affect ( $F = 6.416, p = 0.00$ ) indicating a significant difference in image content between groups. A secondary profile analysis examined the perceived functions of imagery for each group and also revealed a significant group effect ( $F = 30.415, p = 0.00$ ).

**Discussion** The findings of this study demonstrated that an athlete's image content (what they are imaging) and image function (why they are imagining it) is influenced by their predisposition to be confident or anxious. This further supports recent research trends that have examined image content and image function separately. Further research into the role of an athlete's psychological states in influencing imagery is justified to help gain a better understand of the reasons why an athlete engages in imagery.

**A STUDY OF THE CO-RELATION BETWEEN SELF-EFFICACY AND FEAR OF SUCCESS AMONG PROFESSIONAL ATHLETES**

AYAZI, M.

ISLAMIC AZAD UNIVERSITY, ROUDEHEN BRANCH

A Study of the Co-relation between Self-efficacy and Fear of Success among Professional Athletes Islamic azad university Roudheh branch Ayazi, Karimi, Divkan, Shahbazi, Adeli Faculty member, Physical Education, Islamic Azad University at Roudheh Researcher, HooshAfzar Research Institute, Tehran Faculty member, Physical Education, Islamic Azad University at Tehran shargh PhD student of sport management, Shahid Rajaei Teacher Training University Master physical education

**Introduction** Self-efficacy which was presented by Bandura, is the nucleus of social cognition theory. self-efficacy are, fulfilling the functions successfully, vicarious experiences, social persuasion and physiological emotional situation (Bandura, 2000) Fear of success is one of the preventive factors on the way to success and progress (Campbell & Fleming 2000). fear of success generally reduces self efficacy (Carway et al. 2003). The goal of this research is to recognize the relation between self-efficacy and fear of success among professional athletes in individual sports.

**Methodology** 135

athletes with at least five years of championship athletic record were selected by random sampling. They filled in an athletes' self efficacy questionnaire (Bandura 2000), Cronbach's alpha of 0.90 and also athletes' fear of success questionnaire (Metzler & Conroy 2004) Cronbach's alpha of 0.91. Result The results show that there is a significant reverse correlation between social persuasion subscale and fear of success ( $P>0.05$ ,  $r = -0.54$ ), and between emotional status and fear of success ( $P>0.05$ ,  $r = -0.62$ ). There is a direct significant correlation between vicarious experiences and fear of success ( $P>0.05$ ,  $r = 0.30$ ). No significant correlation is reported between success in fulfilling functions and athletes' fear of success. ( $P<0.05$ ,  $r = -0.10$ ). General findings show that there is a significant reverse correlation between total score of self efficacy and fear of success variable ( $P>0.05$ ,  $r = -0.44$ ). Discussion The results agree with; Bandura, 2001; Millen, 2000; Caraway 2003. According to them social persuasion increases the chance of success, and accomplishment anticipation and assert self efficacy is a social skill, also competition has a significant role in fear of success. General results of the study show that as self efficacy increases, their fear of success decreases and success chance will hence rise. Reference Bandura, A. (2000). ## DEVELOPMENT OF A PSYCHOLOGICAL STRATEGIES SCALE FOR JAPANESE ATHLETES AND ITS FACTOR STRUCTURE

MURAKAMI, K.

TOKYO UNIVERSITY OF SCIENCE

Introduction A number of measures estimating athlete's mentality for the purpose of increasing competitive ability have been proposed so far. In Japan, there was no method particularly designed to evaluate an athletes' psychological strategies required in a competitive setting. Therefore, the aim of this study is to develop a measure, which is used for the evaluation of strategies increasing psychological skills. Identifying the effective mental training methods would benefit providing effective continuous psychological support for athletes. Methods Data were obtained from a sample of 537 athletes (male 339, female 198; Age  $20.3 \pm 2.10$  years) competing across a range of performance standards in a wide variety of sports. Based on "Test of Performance Strategies (TOPS)" by Thomas et al. (1999), a questionnaire was prepared which was consisted of 7 categories, including goal-setting, self-analysis, emotional control, imagery, concentration, positive thinking, and self-talk. Items were also collected from free writing, which were classified into 52 items that may represent each category. All athletes participated voluntarily in the study, the instrument typically taking between 20 and 30 min to complete. Results To examine the internal consistency of the items, we calculated the correlation coefficient between the summation of item scores in the scale and the rated scores in each item. As a result, a significant correlation was obtained in the range of  $r = .39-.78$  ( $p < .01$ ) in all items, which showed the internal consistency. Factor analysis (principal factor solution, promax method) was employed to detect factor structure of questionnaire items. For competitive situations, within the questionnaire 8 factors were derived from 35 items and named as follows: emotional control, self-talk, self-analysis, imagery, psych-up, routine, game plan and goal setting. Discussion Exploratory factor analysis of the psychological strategies yielded very clear factor structure. The findings of the factor analysis, together with the descriptive statistics presented for each subscale, clearly support previous literature (Vealey, 1988; Defrancesco and Burke, 1997; Thomas et al., 1999) in identifying the use of motivational (e.g. self-talk and goal setting), imaginal, and emotional control strategies as an important feature of athletes' psychological preparation for competition. References Defrancesco, C., & Burke, K. (1997). Performance enhancement strategies used in a professional tennis tournament. International Journal of Sport Psychology, 28, 185-195. ## ATTENTIONAL ABILITIES, PROBLEM SOLVING SKILLS AND COPING STYLES IN HANDBALL PLAYERS

NICOLOSI, S., CILIA, S., LIPOMA, M.

KORE UNIVERSITY OF ENNA

Abstract In open skill sports, athletic performances aimed to strategic objectives must fit quickly to environmental changes. This kind of adjustments requires the shifting of attentional focus to select and process the informations useful for the performance. During the game, the handball player should consider his position, follow the opponents and – at the same time – evaluate speed and directions of the others players moving around him. The main purpose of our research is to analyse the relationship between coping and attentional styles in handball players and non-athletes, measuring attentional abilities, problem solving skills, and coping styles. Methods The aims of this research were: - the study of situational coping and coping styles in handball players: in particular we investigate the cognitive and emotional variables in stressful conditions contest-related; - the study of attentional styles in handball players; - the evaluation of attentional abilities, working memory and problem solving skills - and their relations with coping - in handball players. 40 athletes and 40 non-athletes, aged from 18 to 40 years and paired by gender, were involved. The instruments used were: - Test of Attentional and Interpersonal Style by Nideffer (1976) - Coping Orientation to the Problems Experiences, New Italian Version by Sica & al. (2008) - Attention and Concentration Test: reaction times, digit span, and shifthing by Di Nuovo (2000) - WAIS-R: Block design and Arithmetic tests by Wechsler (1981) Results and discussion The study identifies styles and cognitive factors involved in coping and attentional processes in handball players. These variables have not been studied in relation to coping and problem solving in handball players. Previous research has demonstrated that 'in sport such as soccer, basketball and tennis, the athlete is expected to alter attentional styles both in width and direction, occasionally quite rapidly' and 'as a result of an incompatible attentional styles, athletes may damage performance' (Tenenbaum & Bar-Eli, 2007). According to Nideffer's conclusions (1976), we will expect similar results in attentional styles, moreover the study analysed their relationships among with coping and problem solving. ### MENTAL SKILLS IN ELITE VOLLEYBALL PLAYERS

DELITALA, L., FADDA, D., MIGLIACCIO, G.M., LOI, A.

ITALIAN NATIONAL OLYMPIC COMMITTEE

**MENTAL SKILLS IN ELITE VOLLEYBALL PLAYERS** Delitala L., Fadda D., Migliaccio G.M., Loi, A. Italian National Olympic Committee (CONI) - Sardinia Introduction Psychological variables are very important for success in sports and affect both individual (self-efficacy and motivation), both team (cohesion and collective efficacy). Indeed for the same physical, techniques and tactics characteristics, some athletes or teams achieve excellent performance, while also fail to emerge. The purpose of this work is to study the mental skills of athletes engaged in high-level volleyball and compare them with those of less successful players. We investigated some psychological variables that, according to sports literature (Williams & Krane, 2001; Gould & Maynard, 2009), appear to be determining factors for peak performance: efficacy beliefs, cohesion, motivational orientation and personality traits. Methods In collaboration with the CONI we recruited a sample of 112 Italian volleyball players ( $F=58$ ;  $M=54$ ) aged between 14 and 38 ( $M=25.31$ ;  $SD=5.3$ ), divided into medium ( $n=54$ ) and high level ( $n=58$ ). They completed the following tests: Task and Ego Orientation in Sport Questionnaire (TEOSQ); Group Environment Questionnaire (GEQ); Big Five Adjective (BFA) and a new sport-specific test that assesses self and collective efficacy (Volleyball Efficacy Beliefs Scales-VEBS; Guicciardi, Fadda & Delitala). To evaluate the differences between the two sub-samples we conducted a multivariate analysis of variance (MANOVA) using level of competition and gender as independent variables, and the average scores of scales as dependent variables. In a subsequent analysis, we tested the influence of some variables related to the gaming experience (years of practice, sets played in a game). Results MANOVA showed that among the psychological skills considered, personal and collective efficacy beliefs differentiate elite from mid-level players. Important gender differences emerged: boys reported significantly higher scores in almost all scales. Moreover, the gaming experience seems to have a significant influence on the variables investigated for both levels. Conclusions This study has shown that there are significant differences in mental abilities depending on the level of competition, gender and gaming experience. The knowledge of the features of elite athletes may be useful to provide mental training programs relevant to successful performance. References Gould, D., & Maynard, I.W. (2009). ### GOLFERS' USE OF IMAGERY AND SELF-TALK AS PROBLEM AND EMOTION FOCUSED COPING STRATEGIES DURING THE WALK TOWARDS, AND IMMEDIATE PREPARATION TO EXECUTE, GOLF STROKES UNDER STRESSFUL CONDITIONS.

LONGSTAFF, F.J., ROBERTSON, K., WOLFSON, S., PARTINGTON, S.

NORTHUMBRIA UNIVERSITY

**Introduction** Golfers have been found to employ the use of imagery and self-talk as coping strategies during stressful situations. Both imagery and self-talk are widely recommended as emotion focussed coping strategies (Jones, 2003). However, there is limited understanding as to how imagery and self-talk are used as problem focussed coping strategies. In golf, the use of imagery and self-talk for this purpose is potentially useful given the problem-solving nature of the game. This study examined how golfers' of differing skill levels, used imagery and self talk as problem and emotion focussed coping strategies during the approach to, and immediate preparation to execute, golf strokes under stressful conditions. **Methods** Upon gaining ethical clearance from the School Ethics Committee (SEC) 145 competitive male golfers were recruited for the study. All golfers completed a purpose designed 8 item questionnaire ( $ICC = 0.85$ ) that assessed their use of imagery and self-talk as problem and emotion focussed strategies during the walk towards, and immediate preparation to execute, golf strokes under stressful conditions. Responses were made on a 5 point likert scale. Results Results from a mixed factorial ANOVA revealed that golfers used imagery and self-talk as problem focussed coping strategies more than emotion focussed coping strategies ( $P<0.005$ ). Moreover, golfers used imagery more as a problem focussed coping method than self-talk ( $P<0.05$ ). When golfers used imagery and self-talk as problem focussed coping strategies they reported externally planning how to play the golf stroke under stressful conditions rather than internally rehearsing its execution. No skill level differences were found in golfers' use of imagery and self-talk as problem and emotion focussed coping strategies. **Discussion** Results appear to suggest that golfers adopt a pragmatic approach to their use of imagery and self-talk when coping with golf strokes under stressful conditions. Instead of using imagery and self-talk to control their emotions golfers report using the strategies to plan how to play the golf stroke that they are presented with. It is likely that golfers make more use of imagery than self-talk for serving this function because although self-talk can be used to facilitate the planning of golf strokes, it does not have the dimension to it that imagery does in allowing players to estimate and imagine how the ball will react in the prevailing conditions. Additionally, in accordance with the multifunctional nature of imagery and self-talk, it may be possible that taking an active approach to a stressor itself may in turn suppress potentially negative emotions. References Jones MV. (2003) *The Sport Psychologist*, 17, 471 - 486

### MENTAL TOUGHNESS, STRESS, APPRAISAL & COPING IN ATHLETES

INGRAM, S.

UNIVERSITY OF WARWICK

**Mental Toughness, Stress, Appraisal & Coping in Athletes** Ingram, S.C.1; Carter, D.C.2; Polman, R.C.J.3; Taylor, J.A.4 IDH, University of Warwick, UK; 2. UK; 3. VU, Melbourne, Aus.; 4. UCLan, UK. Aims Mental toughness (MT) and the ability to cope with stress are regarded by many as important contributors to success in sport. Although there has been research examining the relationship between MT, coping and coping effectiveness, to date little attention has been paid to the role of MT in the appraisal of stressful events. Therefore this two part study examined the relationship between stress, appraisal and mental toughness. **Method** In study one, 90 (73 males, 17 female) athletes (50 cyclists and 40 rugby players) with an average age of 32.4 years completed the MTQ48. In study two, those who scored in the top ( $n=8$ ) and those in the lowest ( $n=8$ ) 10% on the MTQ48 engaged in a semi-structured interview where they were asked about a self-selected stressful event in their sport. The interviews addressed the appraisal of the stressor as well as the coping strategies employed and their effectiveness. **Results** Content analysis of the qualitative data showed that those high in MT reported more challenge appraisals compared to those in the low MT group, who were more likely to appraise the self-reported stressful event as a threat. Also, the athletes in the high MT group relied on either Problem Focussed Coping (PFC) or Emotion Focussed Coping (EFC) which they regarded as being effective. This was supported by the experience of positively toned affect e.g. relief, pride. In contrast, those in the low MT group relied on

avoidant coping which they did not regard as being effective. Those athletes perceived more in the way of negatively toned emotion such as anxiety and anger. This resulted in reduced enjoyment and performance. Conclusion Although similar stressors were reported by the participants, the way these stressors were appraised varied with the level of MT. This suggests that mentally tough individuals are more likely to perceive a stressful event as a challenge rather than a threat. Perceiving a stressor as a challenge is more likely to result in lower levels of perceived stress and more positively toned emotions. In addition this appears to be related to the use of effective coping strategies. This is in turn related to a more enjoyable experience and most likely to increased performance. Athletes with lower levels of MT were more likely to use avoidant coping strategies. Such strategies have been shown to be maladaptive, in particular in the long term. This research suggests that enhancing levels of MT or helping athletes with stress appraisal and the teaching of adaptive coping strategies could be beneficial for both enjoyment and performance. **Introduction** In sport, team cohesion has been viewed as the most important small group variable. A considerable amount of research has investigated both antecedents and consequences of team cohesion and cohesion has a significant impact on athlete's attitude, motivation, behavior, and performance. Less attention in sport science has been related to the Social Identity Approach. Studies have demonstrated that team identification motivated team members to work for the team, and moreover it has a positive impact on team members' attitudes and behaviours. Mental Toughness (MT) in a sporting context has been defined as 'the ability to consistently perform toward the upper range of your talent and skills regardless of competitive circumstances' (Loehr, 1994, p. 5) and has been suggested as containing mental, emotional and bodily toughness (Mack & Ragan, 2008) that all relate to player attitude and behaviour in competition. The aim of this study was therefore to investigate the relationship between elite football player's identification with their team and their perceived mental toughness. **Methods** Seventy five footballers (mean age  $24.7 \pm 5.7$  years) from eight teams in the Norwegian premier league ( $n = 42$ ) and first division ( $n = 33$ ) completed a 6-item scale assessing team identity (TI; De Backer et al., 2010). The questions are scaled from 1 to 7, a higher score indicating a higher degree of social identification. The Mental, Emotional and Bodily Toughness Inventory (MeBTough, Mack & Ragan, 2008) contains 43 items measuring three toughness aspects; Mental Toughness (MT), Emotional Toughness (ET), and Bodily Toughness (BT). The questions are scaled from 1 to 4 with a higher score indicating a higher perception of toughness. Results TI (mean =  $5.6 \pm .94$ ,  $\alpha = .80$ ) was correlated with MT (mean =  $3.3 \pm .41$ ,  $\alpha = .79$ ,  $\rho = .36$ ,  $p < 0.01$ ), ET (mean =  $3.0 \pm .40$ ,  $\alpha = .83$ ,  $\rho = .34$ ,  $p < 0.01$ ) and BT (mean =  $3.1 \pm .41$ ,  $\alpha = .79$ ,  $\rho = .26$ ,  $p < 0.05$ ). **Discussion** The findings indicate that players' identification to the team was relatively strong and that their perceived level of toughness on each subscale was relatively high. The findings also indicate that team identity is positively related to Mental Toughness, Emotional Toughness and to a lesser extent Bodily Toughness but due to the cross sectional design of the study causality cannot be assumed. ### THE DEVELOPMENT OF SELF-REGULATORY PROCESSES IN YOUNG ELITE BASKETBALL PLAYERS

HOLST, T., STADTMANN, T., KELLMANN, M.

RUHR-UNIVERSITY OF BOCHUM

**Introduction** Action control processes cover all those self-regulatory processes involved in implementing a purpose and holding on to that initiated action up to the point of goal-attainment. There are two self-regulation programs: action and state orientation. While in the first program, action orientation, all mental processes are geared to convert the actual into the target state, the second program, state orientation, focuses on analyzing a past, present and future situation. This study extends previous research on the action and state orientation in athletes (Beckmann, 1987) by investigating the development of self-regulatory processes in young elite Basketball players of different ages. **Methods** The questionnaire Action Control Scale in Sport (HOSP) was administered to young (12-20 years of age) German basketball talents in the course of the common research project "Basketball Talents" by the Federal Institute of Sport Science, the German Basketball Association and the Ruhr-University Bochum. The HOSP consists of three factors: failure related, decision related and performance related action orientation. A MANOVA with the factors sex and age was conducted for the three dimensions of the questionnaire. The sample consists of  $n = 599$  (female = 209, male = 390) athletes. Results For failure related action/state orientation, the MANOVA revealed a main effect for sex ( $F(1) = 9.602$ ,  $p < .01$ ) as well as for age ( $F(9) = 4.74$ ,  $p < .00$ ). The post-hoc test reveals significant differences between the groups of the ages 12-14 and the groups of the ages 15-18. **Discussion** The significantly stronger failure related state orientation of female players revealed in this sample so far cannot be reinforced by other findings. With increasing age, the basketball players show an increase in their state orientation after failure. An important point for this development seems to be the transition between the ages of 14 and 15 as the results show a significant difference between the age groups  $<14$  and  $>15$ . The performance related score, however, revealed an action orientation for all ages. These results corroborate the findings of Beckmann (1987), claiming the combination of failure related state and performance related action orientation to be common for elite athletes. It remains unclear whether this effect is due to selection or to socialization. With the help of a longitudinal design the following question could be explored: Do young athletes proceed to an elite level because they possess this combination of failure related state and execution related action orientation, or do they develop this successful combination over time? #### INTER-ARM COORDINATION INFLUENCES LEG KICK AND IS CORRELATED WITH ENERGY COST IN FRONT CRAWL

CRETENAND, F.1, SEIFERT, L.2, DADASHI, F.3, KOMAR, J.2, AMINIAN, K.3, MILLET, G.P.1

1: ISSUL-DEPARTMENT OF PHYSIOLOGY UNIL (LAUSANNE, SWITZERLAND), 2: CETAPS LABORATORY (ROUEN, FRANCE), 3: LMAM-EPFL (LAUSANNE, SWITZERLAND)

**Introduction** The aim of this study was to investigate the correlation between inter-arm coordination and energy cost in front crawl. We hypothesised that discontinuity between propulsive phases within stroke is likely to increase energy cost, eventually by increasing intra-cycle speed variability or drag. **Methods** 10 swimmers ( $18.0 \pm 4.5$  yr,  $176.6 \pm 5.9$  cm,  $66.3 \pm 7.1$  kg) performed in a 50-m indoor pool 2 separate sessions of 3 300-m trials at a constant submaximal intensity with 5-min rest in front crawl (Fc). The intensity was 80% of Fc 400-m personal bests. Each trial was performed randomly in a different coordination mode. The swimmers were asked to swim in a freely-chosen coordination mode (Co Free), in a catch-up mode (Co B) and in a superposition mode (Co C), quantified by the index of coordination (IdC) [1]. Leg kick (LK) and stroke rate (SR) were also recorded. Energy cost (EC) was calculated from gas exchanges measured by a portable system (K4b2, Cosmed, Rome, Italy) connected to a snorkel (Aquatrainer). **Results** The IdC of Co B was  $32.9 \pm 25.2\%$  lower ( $p < 0.001$ ) than the IdC of Co Free. There was no difference between IdC of Co C and IdC of Co Free. A correlation was found between IdC and LK ( $r = -0.42$ ,  $p = 0.02$ ) but not between IdC and SR ( $r = 0.17$ ,  $p = 0.37$ ). The partial correlation between EC and IdC controlling the effect of LK was significant ( $r = -0.57$ ,  $p = 0.001$ ) while the partial correlation between EC and LK controlling the effect of IdC was not significant ( $r = 0.16$ ,  $p = 0.42$ ). **Discussion** At moderate speed, the front crawl swimmers were able to decrease their IdC compared to the freely-chosen coordination but not to increase it. To maintain velocity despite a larger discontinuity between propulsive phases, the swimmers increased their LK without changing their SR. This increase in LK might improve the propulsion and keep a better horizontal body alignment, therefore reducing active drag [2]. Since EC was mainly affected by inter-arm coordination, one may speculate that the relative propulsive time is a determinant factor of economy in front crawl. **Bibliography** 1. Chollet, D., S. #### KINEMATICS AND NEUROMUSCULAR RECRUITMENT OF VERTICAL TREADMILL RUNNING

JORDAN, A., BARNES, A., CLAXTON, D., FYSH, M., PURVIS, A.

SHEFFIELD HALLAM UNIVERSITY

**Introduction** A vertical treadmill (VT) is being developed for the physical conditioning or rehabilitation of athletes. It requires a running action in a recumbent or supine position on a vertically hung, non-motorised treadmill whilst the limbs are supported with overhanging resistance cables. The aim of this study was to describe the kinematics and neuromuscular recruitment pattern of VT running. **Methods** Thirteen active males aged  $24.8 (7.1)$  years, height  $1.8 (0.1)$  m, body mass  $77.7 (8.8)$  kg undertook two familiarisation sessions to determine self-selected (SS) running speed. On a third visit, at the SS running speed, sagittal plane kinematics of the ankle, knee and hip were collected using a motion capture system (200Hz). Activation of major leg muscles was determined by synchronised electromyography. **Results** Participants adopted a SS running speed of  $2.12 (0.38)$  m/s and a cadence of  $150 (20)$  steps/min. with a stance phase of  $32.9 (6.6)\%$  of the gait cycle. Ranges of motion at the ankle, knee and hip were  $29.8 (3.6)$ ,  $38.9 (8.7)$  and  $34.8 (6.6)^\circ$  respectively. The hamstrings were active between 0-30% of gait cycle and again at 57-100%. Gastrocnemius (GA) were both active 0-49% and 68-100%. Tibialis Anterior was active 0-8% and 15-100%. Rectus Femoris (RF) was active between 10-83% of gait cycle. **Discussion** VT running elicits similar SS speed ( $2.25$  m/s, Koga et al. 2009) and stance phase (31.1%, Mann et al., 1980) to horizontal treadmill running. During VT running, the hamstrings pull the leg against the treadmill and resistance cables. RF initiates in stance to flex the hip and to control hamstring activity which ceases in late stance, thus hip hyperextension does not occur (peak extension  $0.3 (5.7)^\circ$ ) as observed in horizontal running (Mann et al., 1980). GA activity and peak plantarflexion ( $20.4 (4.9)^\circ$ ) after toe off indicate a propulsion phase seen in horizontal running (Mann et al., 1980). However, the muscular force is likely not as high due the absence of body mass loading. In swing, peak knee flexion ( $64.4 (8.1)^\circ$ ) was driven by the RF flexing the hip, not by hamstring activity. In late swing the RF extended the knee alone since the Vastii muscles were inactive. The results indicate that VT running targets muscles associated with the posterior chain that are essential for running performance and injury prevention (Askling et al., 2003). In conclusion, the VT shares many similarities with horizontal running without impact loading thus it might be appropriate for injury rehabilitation and physical conditioning for overground running. **References** Askling C, Karlsson J, Thorstensson A. #### AGE-SPECIFIC NEUROMUSCULAR INTERACTION DURING HUMAN RUNNING

SANO, K.1, ISHIKAWA, M.1, AKIYAMA, M.1, HOFFREIN, M.2, URATA, T.1, ITO, A.1

1: OSAKA UNIVERSITY OF HEALTH AND SPORTS SCIENCES, 2: NEUROMUSCULAR RESEARCH CENTER, DEPARTMENT OF BIOLOGY OF PHYSICAL ACTIVITY, UNIVERSITY OF JYVÄSKYLÄ (FINLAND)

**Introduction** The adaptations that occur in the motor system with advancing age cause a range of changes in motor performance. The question regarding the age-specific neural activation strategies during dynamic movements is very relevant, as it may explain better the difference in behavior of the muscle-tendon interaction during locomotion. The purpose of the present study was to examine whether the age-specific muscle activation profiles exist for the age-specific muscle-tendon interaction during running. **Methods** 12 elderly subjects run with a natural cadence ( $1.9 \pm 0.2$  m s<sup>-1</sup>) on a treadmill for approximately 30 seconds. Similarly, 12 young subjects of equivalent height and leg length run with the same speeds to the elderly. The fascicle length and muscle-tendon junction (MTJ) of gastrocnemius medialis (MG) during running were monitored by the high-speed ultrasonography. Simultaneously, the EMG activities of MG and tibialis anterior (TA) were recorded with the movement analysis by the VICON movement analysis system. The changes of Achilles tendon (AT) length was calculated from the changes of MTJ and the changes of the AT interaction on the calcaneus during running. **Results/discussion** The MTU length behavior during running did not show any significant differences between young and elderly. However, the activation profiles did not show similar between young and elderly. The EMG ratio of MG to TA activation was significantly greater in elderly than in young

during the pre 50ms phase before contact, but that was greater in young than in elderly during short latency reflex and braking phases. The EMG ratio of preactivation to braking phase of MG was significantly greater in elderly than in young. In contrast, that of TA was significantly greater in young than in elderly. In the muscle fascicle and tendon levels, the MG fascicle length at the contact was shorter in elderly than in young. In corresponding to the fascicle behavior, The AT length at contact was greater in elderly than in young, and thereby was stretched equally in both groups. These results suggest that elderly may increase the agonist MG preactivation in order to take up the slack of AT before contact, and thereby utilize the tendon elasticity. However, it is not clear why elderly can increase the antagonist TA activation during the braking phase and utilize the tendon recoil effectively during the push-off phase.

## LOWER EXTREMITY JOINT LOADING DURING WALKING WITH MBT SHOES IN ELDERLY MEN

BUHECKER, M., PFUSTERSCHMIED, J., WAGNER, H., MÜLLER, E.

UNIVERSITY OF SALZBURG

**INTRODUCTION:** Age-related impairments in neuromuscular function are often linked to a redistribution of mechanical loads in lower extremity joints during locomotion. As DeVita & Hortobágyi (2000) and Karamanidis & Arampatzis (2009) demonstrated, elderly have a distal to proximal shift in power production and an increase in medial knee joint loading while performing daily activities. Since rational footwear is supposed to provide functional control for aberrant loads in people with proprioceptive deficits (Buchecker et al. 2010), we hypothesized a readjustment of kinetic walking patterns in this age cohort when using MBT shoes. **METHODS:** Eight elderly ( $60.3 \pm 4.0$  yr) and eight young ( $27.0 \pm 5.0$  yr) men, all healthy and familiar with MBT, volunteered. Participants walked at  $5.4 (\pm 0.4)$  km/h for eight trials with standard and MBT shoes, respectively. Kinematic and kinetic measurements were conducted via a Vicon system using eight cameras (250 Hz) and an AMTI force platform (2000 Hz). An inverse dynamic approach was performed for the calculation of lower extremity joint moments and powers. Data were analyzed over the stance phase of the right leg by a two-way repeated measures ANOVA (group x shoe), followed by t-tests as post-hoc procedure when appropriate. Statistical significance was set a priori at  $\alpha < 0.05$ . **RESULTS:** Main effects of shoe revealing decreases of joint moments and powers for the MBT situation were found (all  $P < 0.05$ ,  $\eta^2 > 0.14$ ). Both groups demonstrated reduced concentric and eccentric work at the ankle joint as well as decreased plantarflexor impulses with MBT (all  $P < 0.05$ ). In contrast to young adults, walking with MBT produced less positive and negative work at the knee and diminished concentric hip work in elderly (all  $P < 0.05$ ). Similar results were seen for peak external knee adduction moments and for knee and hip extensor impulses during initial half of stance, showing no differences for the young (all  $P > 0.05$ ), but decreases for the elderly (all  $P < 0.05$ ) when using MBT. However, high variability in the young made it difficult to detect significant interactions. **DISCUSSION:** Data suggests MBT shoes create different locomotor strategies among age groups, with the more systematic effects provoked in the elderly. Present results highlight that wearing MBT may be a beneficial option for this group of people in changing the mechanical environment for the knee and hip joint. Therefore, using MBT shoes might positively impact preventive efforts to reduce the age-associated increased risk of falls and/or development of knee osteoarthritis. **REFERENCES:** Buchecker et al. ## FRONTAL AND SAGITAL PLANE PERTURBATIONS DURING WALKING EVOKE SPECIFIC RESPONSES OF CALF MUSCLES

OLIVEIRA, A.S.1,2, FARINA, D.3, KERSTING, U.G.1.

1 AAU (AALBORG DENMARK), 2 CAPES FOUNDATION (BRASILIA, BRAZIL), 3 GEORG-AUGUST UNIVERSITY (GÖTTINGEN, GERMANY)

Introduction Slips are common experiences during daily activities and sports, which require immediate responses from the neuromuscular system in order to regain the balance. Although several studies about balance loss have been conducted on backward perturbations, little is known on balance loss by the frontal plane perturbations. Therefore, the aim of this study was to compare initial changes in ankle kinematics and electromyography (EMG) during slips in the sagittal (backward) and frontal planes (leftward and rightward). **Methods** Eight healthy men were asked to walk along a 7-m walkway, stepping with the right foot on a moveable platform [1] in the middle of this path. The protocol included no perturbation trials (BASE) and four classes of perturbations (10 cm translations): foot displacement forward (FW), backward (BK), leftward (LF) and rightward (RI). Right ankle joint angles in the frontal (eversion/inversion, ANK-F) and sagittal (flexion/extension, ANK-S) planes as well as EMG from peroneus longus (PER), gastrocnemius lateralis (GL) and tibialis anterior (TA) were collected. Ankle joint angles and EMG at BASE were subtracted from FW, LF and RI trials (BK were excluded), such that thresholds were defined based on the individual's movement variability within the BASE trials. Onset latencies for EMG and changes in joint angle were determined and normalized to one gait cycle (%GC) starting at touch-down of the perturbed foot. **Results** One-way ANOVA revealed ANK-S onset during FW (mean $\pm$ SE:  $9 \pm 1.3\%$ GC) were significantly faster ( $p < 0.05$ ) when compared to LF and RI (FW:  $20 \pm 4$ ; RI:  $18 \pm 3.2\%$ GC, respectively), while ANK-F (FW:  $12 \pm 3$ ; LF  $8 \pm 1$ ; RI:  $10 \pm 2\%$ GC) showed no significant differences. TA EMG onsets for FW ( $11.8 \pm 2\%$ GC) were significantly faster ( $p < 0.05$ ) when compared to LF and RI (LF:  $20 \pm 4$ ; RI:  $25.2 \pm 3\%$ GC, respectively). On the other hand, GL onsets for LF ( $6 \pm 1\%$ GC) were significantly faster ( $p < 0.05$ ) when compared to FW and RI (FW:  $13 \pm 2$ ; RI:  $18.2 \pm 2\%$ GC, respectively). PER (FW:  $4 \pm 1$ ; LF  $9.4 \pm 2$ ; RI:  $8.9 \pm 2\%$ GC) showed no significant differences ( $p = 0.06$ ). **Discussion** EMG activity during FW shows increased TA and PER activity, providing stability immediately during slipping, in order to stabilize the ankle joint in the sagittal plane, while plantar flexors (as GL) are likely to be inhibited by reflex components related to TA muscular length [2]. On the other hand, during LF and RI slips there are faster muscular reactions for GL and especially PER, which may be a mechanism to stabilize the ankle during these faster kinematic changes in ANK-F regardless the direction. In this way, there are specific muscular requirements depending on the perturbation direction, for which maintaining ankle stability in the frontal plane requires more complex interactions of ankle muscles. **References** 1 - Van Doornik J, Sinkjaer T. ## THE EFFECTS OF SHOCK-ABSORBING INSOLES ON GRF CHARACTERISTICS DURING UPHILL WALKING AND RUNNING IN MILITARY BOOTS

HANLEY, B., PAISIS, P., HAVENETIDIS, K., BISSAS, A.

LEEDS METROPOLITAN UNIVERSITY

**Introduction** Despite the fact that stiff military combat boots has been associated with muscle fatigue and reduction in joint mobility (Scully & Besterman, 1982), there is still limited research in this area. Moreover, shock-absorbing insoles have been used extensively by military personnel in an attempt to reduce the magnitude and rate of impacts generated during walking and running. The aim of this study was to measure ground reaction force (GRF) characteristics during walking and running while wearing running shoes and military boots, with and without commercial insoles. **Methods** Seven trained males ( $24 \pm 2.6$  years) walked at 5 km/hr and ran at 10 km/hr with a 5% gradi-

ent on a Kistler h/p/Cosmos Gaitway treadmill. The participants completed three trials with different footwear conditions at each speed. The conditions were the participants' own running shoes, a military boot with no insole, and the military boot with a pair of Lonsdale performance EVA insoles. The sampling rate was 1000 Hz and data were recorded for 30 s during the fourth minute of each trial. GRF variables such as impact peak force and push-off rate were determined. A one-way ANOVA was conducted on each set of data with Tukey post hoc tests; alpha was set at 0.05. Results During walking, peak impact force was lower when participants wore their own running shoes ( $0.11 \text{ BW} \pm .08$ ) than when wearing the military boots either with ( $0.41 \text{ BW} \pm .03$ ) or without the insoles ( $0.43 \text{ BW} \pm .04$ ) ( $p < .001$ ). No differences for peak impact force were found during running. Push-off rate during the propulsion phase in walking was found to be significantly lower when wearing the insoles ( $9.9 \text{ BW/s} \pm 0.6$ ) compared to both the no insole condition ( $10.5 \text{ BW/s} \pm 0.9$ ) and the running shoes ( $10.5 \text{ BW/s} \pm 0.5$ ) ( $p = .011$ ), but once again no difference was found when running. No differences were found between shoe conditions for either walking or running in terms of impact loading rate. Discussion The cushioning properties of the running shoes led to a reduced peak impact force compared with the two military boot conditions during walking. Surprisingly, the use of combat boots with insoles did not lead to greater shock absorption than the use of the boots without insoles. The lower rate of force development during propulsion for the insoles might mean less energy is required to maintain a given walking pace. The absence of significant differences when running suggests that the boots are suitable for short military running activities with regard to GRF variables. In summary, the use of insoles did not improve the shock absorption capacity of the military boots. References Scully TJ, Besterman G. (1982). *Milit Med*, 147(4), 285-287.

## THE IMPACT OF INDIVIDUALLY FITTED CARBON INSOLES ON SPRINT PERFORMANCE IN COMPETITIVE CYCLISTS

SCHMIDT, A., KLAUS, S., ROTH, R.

DEUTSCHE SPORHOCHSCHULE KÖLN

Introduction In modern cycling, the spotlight is increasingly being put on the interfaces between man and machine. In this study, the transmission of power from the foot to the pedal by dint of Solestar carbon cycling insoles was optimized. A special active principle, which supports and guides the foot during the entire pedaling cycle. An optimized ergonomics reduces the symptoms of physically overstraining specific to this particular movement and raises the performance brought to the pedal. It was examined whether an improvement of the average performance in a sprint for a period covering eight seconds can be achieved by dint of individually fitted carbon insoles. Methods Each test person ( $n=25$ ) completed three sprint tests of eight seconds each with the standard soles of his own racing bike shoes. After a standardized warm-up phase of ten minutes, a total of three sprints lasting eight seconds each were performed in intervals of five minutes (recovery phase). The performance measurement was done on the test person's own bicycle using a standardized Cyclus 2 gauge from the manufacturer RBM elektronik-automation GmbH. The maximum values and the average sprint performance covering eight seconds were measured in watt during all the sprints. Subsequently, each test person was equipped with suitable Solestar carbon insoles fitted individually to his foot and racing bike shoe. After a phase of getting accustomed to the insoles lasting two weeks, the sprint test (see above) was repeated. Within these two weeks, the test persons completed merely training units in basic endurance without sprint intervals so as to avoid performance-enhancing adjustment effects. Results We examined a total of 25 test persons (5 women, 20 men; average age:  $30.4 \pm 10.87$  years old; a range from 17 to 45 years old, average weight:  $70.05 \text{ kg} \pm 10.82 \text{ kg}$ ). The average sprint performance covering 8 seconds rose from  $896.9 \pm 167.3 \text{ W}$  to  $958.7 \pm 183.0 \text{ W}$  ( $p < 0.001$ ; paired t-test; 95% confidence interval of the change  $48.8 \text{ W} - 75.0 \text{ W}$ ) by  $61.9 \text{ W}$  (around 6.9%). Discussion A jump of the sprint performance in cycling in terms of the complete duration of a sprint covering eight seconds can be effected by dint of individually fitted carbon insoles. The optimization of transmission of power by an even distribution of power over the entire midfoot axis and the support of the arch using individually fitted carbon insoles for racing bike shoes is apparently the decisive factor for these results. ## ANALYSIS OF PLANTAR PRESSURE DISTRIBUTION DURING TYPICAL TECHNICAL GESTURES IN WOMEN BASKETBALL PLAYERS

PAU, M., CAGGIARI, S.

UNIVERSITY OF CAGLIARI

ANALYSIS OF PLANTAR PRESSURE DISTRIBUTION DURING TYPICAL TECHNICAL GESTURES IN WOMEN BASKETBALL PLAYERS Pau, M. and Caggiari, S. Department of Mechanical Engineering, University of Cagliari (Italy) Introduction In basketball, ankle and foot are anatomical sites characterized by high incidence of game-related injuries (35 to 40% of total, Borowski et al., 2008). Since the assessment of the magnitude and location of the maximum stresses at the body-ground interface is important in preventing injuries or reducing their seriousness (Guettler et al., 2006), this study intends to investigate plantar pressure distribution modification occurring during typical actions such as layup, free throws, three-point shots and jump shots. Methods Ten elite regional women basketball players were recruited for the study and asked to perform five repetitions of long and short distance shots and layups, while standing (or jumping and landing) barefoot on a pressure plate. The instrument was set to acquire contact pressure data for 5 seconds (at 200 Hz frequency) divided into 1000 temporal events. Raw data were then post-processed by means of a custom routine developed in the Matlab environment. On the basis of the analysis of the force-time curves, 10 frames (representative of the whole movement) were selected to extract plantar pressure distribution and calculate location and magnitude of the pressure peak in forefoot, midfoot and rearfoot. Results Generally speaking, absolute values of plantar pressure were found to be higher in the forefoot for the three-point shot (768 kPa) and layup (818 kPa), while lower values were observed in the case of free throws and jump shots (483 and 450 kPa respectively). The rearfoot appeared to be generally less stressed (121 kPa for three-point and 76 for free throws) and none of the players practically exploited rearfoot support during jump shots. For layup actions, a 520 kPa peak in rearfoot was estimated. Nevertheless, when the pressure values are expressed in terms of change with respect to basal conditions, three-point shots represent the most challenging condition, as pressure increases about 8-fold in the forefoot, while in layups only 4-fold. Discussion Most gestures investigated required a transfer of body load and push action from the lower limbs to the forefoot, and this resulted in extremely high pressure peaks typically located in the metatarsal region. Although short-distance shots require a minor effort, the pressure increases still remained noteworthy (up to six times higher than basal). Layup originated completely different patterns of pressure distribution as all the plantar subregions underwent significant increases, and thus the whole foot appeared to contribute to the jump action. ## **RUNNING IN TRADITIONAL RUNNING SHOES VS MINIMALIST RUNNING FOOTWARE: A KINEMATIC COMPARISON.**

WALSH, M.

MIAMI UNIVERSITY

**Background.** Since the running boom in the 1970's and the injuries that followed, there has been an interest in developing running shoes that can help reduce the incidence of injury. Recently, one of the emerging philosophies in this area is that allowing the foot to move more naturally could help reduce the incidence of running injury. Recently a number of shoe manufactures developed shoes that allowed the joints of the foot more movement than the typical running shoe. The media has reported on this topic and much can be found online. Most of the material that can be found is based on testimonials and speculation. It is important to examine the differences and fill in the scientific information to determine if the minimalist running footwear has the potential to help lower the incidence of running injuries. To help build a collection of data on this topic, we analyzed running kinematics in 7 runners wearing both minimalist footwear and their normal running shoes. **Purpose.** To examine the kinematic differences between running in traditional running shoes vs minimalist running footwear at different velocities. **Methods.** Seven healthy recreationally runners were ask to run on the treadmill at 3 different speeds for 5 minutes at each speed, in both their normal running shoe and a pair of minimalist shoes. The first speed was a comfortable jog and the next 2 speeds were 0.22 and 0.45 m/s faster. Kinematic data was captured using the Vicon motion capture system. Data was collected during the last minute of each 5 minute interval when the subjects had reached steady state, as controlled using a metabolic cart. The following variables were analyzed: type of foot strike (forefoot or rearfoot), stride length, stride frequency. Additionally the interaction between running speed and these variables was also evaluated. **Results.** Of the 7 subjects 5 were heel strikers and 2 were forefoot strikers for all velocities in the normal running shoes. Of the 5 heel strikers under baseline conditions, 3 became forefoot strikers while running in the minimalist shoes. The 2 forefoot strikers remained as forefoot strikers. Stride length and frequency was lesser and greater respectively in the minimalist running shoes for 4 subjects, while the other 3 subjects showed mixed results that were velocity dependent. In subjects with mixed results the differences tended to emerge at the faster velocities. **Discussion.** The results show that wearing minimalist footwear while running can cause changes in running technique. This was expected, as one of the main differences between the two types of shoes is that the minimalist running shoes do not have a heavily padded heel and therefore a heel strike can be uncomfortable in minimalist footwear. It is not yet known what effect these changes have on injury.

## **EFFECTS OF SLIGHTLY-WEIGHTED-SHOE INTERVENTION ON LOWER LIMB MUSCLE MASS AND GAIT PATTERNS IN THE ELDERLY: A RANDOMIZED CONTROLLED TRIAL**

**Introduction** Flexed-knee locomotion is one of the gait characteristic in the elderly (Ostrosky et al 1994, Begg and Sparrow 2006). This may be partly due to the age-related decline of lower limb muscle mass (LM). Browning et al. (2007) reported that distal leg loads increase lower limb muscle electromyographic activity during walking. The purpose of this study was to investigate the effects of 12-wk slightly-weighted-shoe intervention under the free living on LM and gait patterns in older people. **Methods** A total of 29 healthy participants who had walking habits were randomized to a slightly-weighted-shoe (WS: 493g for each) or normal-shoe (NS: 293g for each) intervention groups. The participants were instructed to maintain their daily physical activity (PA) during 12-wk intervention. Segmental intracellular water (ICW) and muscle thickness (MT) were measured as an index of LM. Gait data were acquired by two-dimensional motion analysis. Participants instructed to walk with their usual speed, and performed a walking task alone or walking with cognitive task (subtracting serial 3s). Walking stability was assessed as a standard deviation of vertical fluctuation of whole-body center of mass (COM fluctuation). The daily PA was monitored by a uni-axial accelerometer and activity record. **Results** The participants did not change their PA during intervention. However, significant increases in the ICW in the upper leg and muscle thickness of rectus femoris (RF) were observed after intervention in the WS group only ( $p < 0.01$ ). For the gait parameters, COM fluctuation during walking under dual-task was significantly reduced in the WS group ( $p < 0.05$ ). In addition, knee joint angle during single-leg standing phase was significantly extended more in the WS group ( $p < 0.05$ ). **Discussion** The WS intervention increased LM, and knee joint angle was extended more during single-leg standing phase. The participants did not change their PA, and thus, the results of this study are likely due to the weighted shoes. The previous study indicated that walking with distal leg loads increase lower limb muscle activities including RF (Browning et al. 2007). The present study demonstrated that slightly-weighted-shoe (plus 200g) interventions may be able to increase LM and change gait patterns in the healthy elderly. **References** Ostrosky KM et al. ## **THE ANTERO-POSTERIOR MOVEMENT OF THE SACRUM AS AN INDICATOR OF THE ANTERO-POSTERIOR MOVEMENT OF CENTER OF MASS IN RUNNING**

HALVORSEN, K., ERIKSSON, M., NILSSON, J., TINMARK, F., GULLSTRAND, L.

KTH ROYAL INSTITUTE OF TECHNOLOGY

**THE ANTERO-POSTERIOR MOVEMENT OF THE SACRUM AS AN INDICATOR OF THE ANTERO-POSTERIOR MOVEMENT OF CENTER OF MASS IN RUNNING** Halvorsen K.1,2, Eriksson, M.1, Nilsson, J.3, Tinmark, F.3, Gullstrand, L.4 1: KTH (Stockholm, Sweden), 2: UU (Uppsala, Sweden), 4:GIH (Stockholm, Sweden), 3: RF-EIC (Lidingö, Sweden) **Introduction** The antero-posterior velocity of Centre or Mass (CoM) fluctuates over a step cycle in running, due to air resistance and to the ground forces acting on the foot of the athlete. The fluctuation is a basic charac-

teristic of a runner's technique, and is believed to influence running performance (Nummela et al. 2007; Støren et al. 2010). The vertical movement of the sacrum has previously been found to well describe the vertical movement of CoM (Gullstrand et al 2009). Can it also be used for the antero-posterior movement? Methods Fourteen male athletes ran on a treadmill at velocities of 10, 12, 14, 16, 18, 20 and 22 km/h. With a motion capture system, the centre of mass was calculated from 40 reflective markers with a model consisting of 13 rigid body segments. At each velocity, 10s of data was used for further analysis. The difference between the minimum and maximum velocity and displacement in the antero-posterior direction was calculated for CoM and the sacrum for each step. The relation between the movement of the sacrum and that of the CoM was assessed using linear regression with data from all velocities. Results The horizontal displacement of the sacrum (median 3.9cm) was almost three times that of the CoM (median 1.4cm). The sacrum displacement increased with running velocity, but CoM displacement did not. The linear regression showed a significant slope (0.34,  $p < 0.001$ ), but small effect size (adjusted R-squared 0.22), meaning that the displacement of sacrum is a limited predictor for CoM displacement. The relation between variation in sacrum velocity (median 0.83m/s) and the variation in CoM velocity (median 0.24m/s) showed better predictive power (adjusted R-squared 0.41), with a clearly significant ( $p < 0.001$ ) slope of 0.15. Discussion The displacement of the sacrum is not a good predictor for CoM displacement in the antero-posterior direction, but variation in sacrum velocity can be useful with the regression coefficients found here. However, due to the moderate R-squared value, average values over several steps should be used. The change in velocity of the sacrum is an interesting measure for real-time feedback to the runner, but it should be noted that the feedback may induce a change in the correlation between the sacrum and CoM velocity without inducing a desired change in CoM velocity. ## A STUDY OF THE STEP LENGTHS IN VELOCITY TEST IN ELITE SOCCER PLAYERS

ESPINOSA-SANCHEZ, M.

NATIONAL UNIVERSITY OF MEXICO

Introduction Because its importance, Soccer players regularly practice sprints (Stolen et al., 2005; Gregorat, 2008). Running 20 m with a standing body Start Posture (SP) evaluates acceleration and Maximum Cyclical Velocity (MCV) (Grosser and Starischka, 1989). The first push-off at start is stepping backwards with the leading foot, giving power in a shorter time and increasing acceleration (Kraan et al., 2001). The maximum velocity depends on step length (SL) and step frequency, and for experienced soccer players step frequency is what mostly contributes to their velocity (Grosser, 1991). Methods Sixteen male elite soccer players (height  $1.77 \pm 0.04$  m; weight  $73.84 \pm 5.20$  kg and age  $28 \pm 5$  years) were tested in 20 m sprints. The times and velocities were measured with a fully automatic system (Foto Finish, Hy-Tek's Meet Manager) at exactly 5 m and 15 m from the starting line. The sagittal sequences were taped to determine SL at SP and at MCV. The degree of linear dependency (Pearson,  $r$ ) has been calculated ( $p < 0.05$ ). The null hypothesis is that there is no relation between the SL involved at SP and at MCV. Results The calculated data (mean  $\pm$  SD): A. Distance between leading foot toes and rear foot toes at SP ( $0.71 \pm 0.094$  m) B. Step backwards ( $-0.11 \pm 0.079$  m). C. First step ( $0.91 \pm 0.098$  m). D. Rear foot first step length ( $1.61 \pm 0.094$  m). E. Time registered to the 5 meters ( $1.49 \pm 0.038$  s). F. First step length in MCV ( $1.42 \pm 0.072$  m). G. Second step length in MCV ( $1.48 \pm 0.080$  m). H. Step frequency ( $4.66 \pm 0.370$  steps / second). I. Time registered to the 15 meters ( $2.84 \pm 0.073$  m). J. Individual's height / stride length\* 100 ( $61.23 \pm 2.574$  %). The significant values are: A-C  $r = -0.518$ , C-D  $r = 0.524$ , F-G  $r = 0.711$ , F-J  $r = -0.777$ , G-H  $r = -0.694$ , H-I  $r = -0.600$ , H-J  $r = 0.655$ , E-I  $r = 0.870$ , F-H  $r = -0.858$ , and G-J  $r = -0.899$ . The other variables are not connected. Discussion The faster individual almost do not step backwards and those that were not between the 10 faster players, step back  $> 20$  cm. A greater step frequency with a greater percentage of the relation stature / stride correspond to a first step SL  $< 1.5$ m. The players with the greatest step frequency ( $> 5$  steps/s) are between the faster players, and are also those with large stature / stride relation. At the MCV, the individuals with the longest stride are between the slowest players, and vice versa. In this study the results indicate that there is no relation between the SL involved in the sprint start and in the MCV. References Gregorat J. (2008). PubICE Standard. Pid: 1064. Grosser M. (1991). ## SYMMETRY OF SUPPORT SCULL IN VERTICAL POSITION IN SYNCHRONIZED SWIMMING

DUBIEL-WUCHOWICZ, K., RUTKOWSKA-KUCHARSKA, A.

UNIVERSITY SCHOOL OF PHYSICAL EDUCATION IN WROCLAW

SYMMETRY OF SUPPORT SCULL IN VERTICAL POSITION IN SYNCHRONIZED SWIMMING Dubiel-Wuchowicz K., Rutkowska-Kucharska A. Department of Biomechanics, University School of Physical Education, al. J. Paderewskiego 35, 51-612 Wrocław, Poland Introduction Biomechanical description of the specific movement structure in synchronized swimming is one of the most important research problems of technique (Hall, 1996, Homma 2008). One of the most difficult technical elements of synchronized swimming is maintaining a vertical position. The performance of this position is made possible by the specific technique of underwater arms movements called support scull. The symmetry of support sculling movements determines the stability of the vertical position and has a large impact on the sport results. Very often the research on symmetry in swimming concerns the techniques of competitive swimming where the spatial symmetry reflects the high-class swimmers (Aujouannet et al. 2004). The aim of the present study is the observation for the symmetry of support scull of right and left upper extremities swimmers with different levels of sport's abilities. Methods Two synchronized swimmers with different levels of sport's abilities (A and B) were filmed under the water while performing 8 cycles of sculling movements. Three-dimensional motion analysis was supported by the SIMI Motion Software. Optical axes of both cameras were arranged perpendicularly to each other. On the basis of three markers set, the angles of wrist elbow and shoulder joints in both upper extremities were computed. The coefficients of variation of time parameters (time of the abduction phase and the adduction phase) and angular spatial parameters were obtained. The dynamical asymmetry index  $DAI(t) = \frac{|Xr(t) - Xl(t)|}{0.5(Xr(t) + Xl(t))}$  was then acquired which is the relative difference between the range of motion of the right and left joint angle. Results Asymmetry characteristics of DAI for the shoulder-elbow-wrist angle (SEW), shoulder-elbow fingers angle (SEF) and elbow-wrist-fingers angle (EWF) for both swimmers are shown. All DAI characteristics are synchronized in time. The dynamical asymmetry index DAI and the coefficients of variation (V) vary between synchronized swimmers. The ability to perform more symmetrical support scull movements characterises the better swimmer. The coefficients of variation of time of abduction and adduction of the right and left limb are: A)  $V_{prawa} = 0.15\%$ ,  $V_{2prawa} = 0.05\%$ ,  $V_{lewa} = 0.15\%$ ,  $V_{2lewa} = 0.09\%$  and B)  $V_{prawa} = 0.2\%$ ,  $V_{2prawa} = 0.12\%$ ,  $V_{lewa} = 0.26\%$ ,  $V_{2lewa} = 0.2\%$ . ## THE EFFECTS OF FOLLOW-THROUGH ON UPPER AND LOWER LIMBS PERFORMANCE DURING STATIONARY TEE BASE-BALL HITTING

HUNG, T.Y., KUNG, J.T., CHEN, S.W., TANG, W.T.

NATIONAL TAIWAN SPORT UNIVERSITY

**Introduction** The follow-through in baseball hitting has dual intention of reducing the risk of injury and preventing interference with the application of force to the ball (Hay, 1993). In addition, sometime coach would suggest hitter to extend follow-through after bat-ball contact to provide more accuracy swing trajectory when hitting. Nevertheless, it is unknown how baseball hitting performance change in difference follow-through, such as comparing a normal follow-through to a extend follow-through. Therefore, the purpose of the current study was to compare baseball hitting performance between a normal follow-through and a extend follow-through. **Methods** One Minor League Baseball (MiLB) athlete subject was enrolled into the study. The Motion Analysis System (Eagle Cameras; Motion Analysis, Inc., Santa Rosa, CA., USA) with 8 infrared rays cameras (200Hz) were used for captured the baseball hitting movement from stationary batting tee. Preceding data collection, 44 reflective markers was placed on the hitter, bat, and ball (Escamilla et al., 2009a, 2009b; Welch et al., 1995). The two best line drive hits were used for data in this study. Dependent t tests were employed to test for differences in kinematic and temporal parameters between the normal follow-through and extend follow-through. **Results** The temporal acceleration phase parameter of normal follow-through (0.18 s) was significantly less time than extend follow-through (0.218 s). There were no significant differences between using normal or extend follow-through in upper and lower extremity angular displacement parameters, stride length, and bat linear velocity at bat-ball contact. Compared with using the normal follow-through (178 deg/s), using the extend follow-through (202 deg/s) resulted in significantly greater peak left knee extension angular velocity. **Discussion** In the current study, upper and lower extremity angular displacement were similar at four events (lead foot off ground, lead foot contact with ground, hand started to move forward, bat-ball contact). Moreover, the result showed no difference in stride length, and bat linear velocity at bat-ball contact. Therefore, the pattern of follow-through would not affect the angular displacement of limbs, linear displacement and velocity parameter. The tendency of some result was similar to hitting biomechanics data presented in previous studies (Escamilla et al., 2009a, Welch et al., 1995). The acceleration phase was significantly spend more time with the extend follow-through. Therefore, subject must start the swing movement early when using extend follow-through in real game baseball hitting. **References** Escamilla R, Fleisig G, DeRenne C. ## BIOMECHANICAL ANALYSIS OF DIFFERENT INCREMENTAL SWIMMING PROTOCOLS. A CASE STUDY

RIBEIRO, J.1, SOUSA, M.1, ABRALDES, J.2, FIGUEIREDO, P.1,3, NAZÁRIO, R.1, VILAS-BOAS, J.P.1,3, FERNANDES, R.J.1,3

CIFI2D, FACULTY OF SPORT, UNIVERSITY OF PORTO, PORTO, PORTUGAL, FACULTY OF SPORT SCIENCES, UNIVERSITY OF MURCIA, MURCIA, ESPAÑA2LABIOMEP, UNIVERSITY OF PORTO, PORTO, PORTUGAL3

Incremental protocols are being commonly used as a standard procedure for swimming aerobic performance assessment. As different step durations of the incremental protocols seems to impose different results, we aimed to evaluate and compare the stroking parameters, swim efficiency, and arm coordination during three incremental and intermittent protocols with different step durations. **METHODS:** An European level triathlete (age: 19yrs; weight: 69kg, height: 175cm) performed 6x200m, 6x300m and 6x400 intermittent incremental protocols ,with 30s rest intervals, being the swimming velocity (v) controlled by a visual pacer (TAR.1.1, GBK-electronics). All protocols were videotaped and images were digitized using the APASystem. Two complete arm stroke cycles of the last 50m lap of each step were analysed. V and stroke length (SL) were calculated using the right hip point as the marker and the stroke rate (SR) was assessed of the ratio v by SL. Swimming efficiency was obtained through the intracycle velocity variations (IVV, assessed by the v coefficient of variation), and the arm stroke efficiency ( $\eta_F$ , calculated through the underwater phase only, Zamparo et al., 2005). The arm coordination was assessed using the index of coordination (IdC, Chollet et al., 2000). **RESULTS:** The SR increased (from 0.44Hz to 0.81Hz) and SL decreased (from 2.65m to 1.99m) throughout all the incremental protocols with a similar behavior. The IVV presents a constant behavior along the steps, with similar results between protocols (comprehended between 0.25 e 0.31) The  $\eta_F$  appear to decrease throughout the incremental steps of each protocol. The IdC values were negative (-11.3%,-19.1%) in the three protocols, presenting an increase at higher swimming intensities, and a slight tendency to be more negative in 6x200m protocol. **DISCUSSION:** The different step durations of the incremental protocols seems to do not to affect the stroking parameters behavior since the SR and SL combination was not modified and is in accordance with the literature. Despite the  $\eta_F$  decreased as the swimmer reach higher swimming intensities, he seems to be able to adapt his stroke technique to maintain IVV (as seen by Seifert et al., 2010). The arm coordination (IdC) presented a slight tendency to be more discontinuous in the 6x300m and 6x400m protocols, which might indicate that the swimmer was in a higher fatigue state (Alberly et al., 2005) as compared 6x200m that is the incremental protocol mostly used by coaches and researchers. **REFERENCES** Alberly, M et al. ## ASSESSMENT OF POWER STRENGTH IN ELITE SOCCER PLAYERS BY MEANS OF VERTICAL JUMP

ZAHALKA, F., MALY, T., MALA, L., GRYC, T., BUZEK, M., HRASKY, P.

CHARLES UNIVERSITY

**Introduction** Implementation of a vertical jump is usually evaluated in three types of execution. Reiser (2006) describes three types of vertical jump. The first type is with knees bent with the help of the upper limbs – countermovement jump – free arms (CMJ-F), the next is with knees bent without the support of the upper limbs – countermovement jump (CMJ) and the squat jump without the help of the upper limbs – squat jump (SQJ). The squat jump without the help of the upper limbs starts from a static position and movement initialization is only in the vertical direction upwards (Bobbert et al , 2005). **Methods** The observing group was composed from top level players (n=30; age=26,4±5,3 years; height=183±4,8 cm; weight=79±7,5 kg). The lower limbs strength was scanned by Kistler Force platform (KISTLER Instrumente AG, Switzerland). Participants performed three types of a vertical jump, T1 – CMJ-F, T2 – CMJ, T3 – SQJ and three successful trials of each type of the jump. The best performed trial was chosen for the evaluation. **Results** The maximum height of the jump was

achieved in the first type when  $h_1 = 0,441 \pm 0,049$  m. This result was better by 12,2% (0,054 m) compared to the jump from standing position without the arm support (T2) and by 21% (0,093 m) higher than the squat jump without the arm support (T3). Variance between the best and worst performance, i.e. jump height (h) was comparable in all types of jump implementation ( $T1var = 0,18$  m,  $T2var = 0,16$  m,  $T3var = 0,17$  m). Decelerating impulse (I1) reached the highest mean value in test T2 ( $I1T2 = 130,3$  N.s), which is higher by 19 % (24,8 N.s) in comparison to test T1. Strength impulse in the take off phase (I2) was highest in T1 ( $I2 = 263,8 \pm 23,9$  N.s), the lower value was in test T3 ( $238,2 \pm 22,1$  N.s). Discussion In the monitored group these mean values ranged T1  $h = 0,441$  m, T2  $h = 0,387$  m and T3  $h = 0,347$  m. In comparison to basketball players, for instance, they are lower; in the study (Ziv and Lidor 2010) there are values of T1  $h = 0,61$  m, T2  $h = 0,439$  m and T3  $h = 0,398$  m. In all types of the vertical jump we noticed shorter times of the braking phase (t1) compared to the time needed for individual the take off (t2). In the case of the braking phase, variance was  $t1varT1 = 0,16$  s and in a reflective phase  $t2varT2 = 0,18$  s. Similar intraindividual variability was found in test T2 at both phases of the take off ( $t1varT2 = 0,11$ , i.e.  $t2varT2 = 0,16$  s). Highest variance was found in the reflective phase in the squat jump without the help of arms, when  $t2varT3 = 0,21$  s. This project was supported by GACR P407/11/P784 and MSM 0021620864. ## RUNNING IN TRIATHLON: THE EFFECT OF PREVIOUS RUNNING EXPERIENCE ON STRIDE PARAMETERS AND KINEMATICS

SCARFE, A.C., LI, F.X.

UNIVERSITY OF BIRMINGHAM

**Introduction** The sport of triathlon combines swimming, cycling and running. However, the movement patterns associated with these disciplines are vastly different from one another and substantial training in any one of these disciplines may have a detrimental effect on the others. Cycling has been proposed to be the underlying cause of the differences in running technique between triathletes and runners (Connick and Li, under review). In order to maximise aerodynamics, cycling is often conducted in an extremely flexed posture; this position requires the hips and knees to be maintained in a flexed position for long durations, which may cause a shortening of the hip flexors. **Methods** In order to investigate adaptations to cycling, running technique of 9 pure triathletes, 9 triathletes with a running background, 9 runners and 9 cyclists were explored using 3D kinematic data collected via a 13 camera Vicon system. All participants carried out 2 minute bouts of treadmill running at randomly assigned velocities (13, 15 and 17km/h). Prior to running measures, static hip flexibility measures were collected using the Modified Thomas Test. **Results** There was a significant main effect of running background on stride length (SL) ( $F(3, 32)=6.67$ ,  $p=0.001$ ); thigh extension ( $F(3, 32)=10.35$ ,  $p=.001$ ) and pelvic tilt ( $F(3, 32)=6.68$ ,  $p=.001$ ). Post hoc measures showed runners exhibited significantly longer SL than cyclists ( $p<0.001$ ) and pure triathletes ( $p=0.004$ ). Cyclists had significantly shorter strides than triathletes with a running background ( $p=0.03$ ). There was no significant difference between pure triathletes and cyclists ( $p=0.24$ ). Runners exhibited greater thigh extension than pure triathletes ( $p=0.005$ ), triathletes with a running background ( $p=0.026$ ) and cyclists ( $p=0.001$ ). Cyclists displayed significantly less thigh extension than triathletes with a running background ( $p=0.003$ ) and triathletes ( $p=0.017$ ). Runners also exhibited significantly greater pelvic tilt than cyclists ( $p<0.001$ ), triathletes with a running background ( $p=0.010$ ) and pure triathletes ( $p=0.008$ ). No significant differences we found between cyclists and triathletes with a running background ( $p=0.105$ ) or pure triathletes ( $p=0.127$ ). No significant differences were found between the triathlete groups in any of the measures. **Discussion** Cyclists exhibit running kinematics that differ most from runners. As these occur in the same parameters as when triathletes are compared to runners, it is likely that the volume of cycling undertaken by triathletes is the causal factor. Triathletes from a running background also exhibit differences in running kinematics when compared to runners but not in comparison to triathletes. It seems that increased running ability when starting out in triathlon levels out when cycling is undertaken as part of triathlon training. **References** Connick, M.J. and Li, F-X. (under review). The effect of running velocity on stride parameters and kinematics in runners and triathletes.

## TREADMILL FATIGUE TILL EXHAUSTION DOES NOT ALTER SOCCER KICKING PERFORMANCE IN FEMALE PLAYERS

KATIS, A., KELLIS, E.

ARISTOTLE UNIVERSITY OF THESSALONIKI

**Introduction** The design of effective training protocols requires an understanding of how technique may change when the player is fatigued, as frequently occurs within a game. Although female soccer is in growth (Ekblom, 1994) few studies have examined kick biomechanics in females (Barfield et al., 2002; Clagg et al., 2009), especially under fatigue conditions. Therefore, the purpose of the present study was to examine the effects of fatigue on the biomechanical characteristics of instep soccer kick in female players. **Methods** Ten female amateur soccer players (age:  $24.4 \pm 4.2$  yrs, height:  $169.7 \pm 5.71$  cm, mass:  $61.8 \pm 5.1$  Kg, training age:  $10.7 \pm 3.1$  yrs) performed 3 consecutive instep kicking trials of a stationary ball prior to and after the implementation of a fatigue protocol, where players had to run on a treadmill until exhaustion (Abdul-Aziz et al., 2005). Three-dimensional kinematics (6-camera Vicon motion analysis system, 120 Hz) including the duration of the kick, ball speed, ball-to-foot speed ratio, linear velocities of the ankle, knee and hip were collected pre and post fatigue. Ground reaction forces were also analyzed using a Bertec platform. An independent two-tailed Student's t-test was used for comparisons between the two kicking conditions. **Results** The results indicated a non-significant effect of fatigue on kicking performance ( $P > 0.05$ ). Particularly, the duration of the kicking trials ( $918 \pm 131$  vs  $876 \pm 90$  msec), ball speed values ( $18.4 \pm 1.5$  vs  $17.4 \pm 1.9$  m/sec), linear velocity of the hip ( $0.7 \pm 0.2$  vs  $0.6 \pm 0.3$  m/sec), the knee ( $2.1 \pm 0.5$  vs  $1.8 \pm 0.4$  m/sec) and the ankle ( $11.3 \pm 1.4$  vs  $10.8 \pm 0.8$  m/sec), vertical ( $756.4 \pm 292.4$  vs  $668.2 \pm 351.1$  N), anteroposterior ( $28.2 \pm 16.3$  vs  $44.1 \pm 21.3$  N) and mediolateral ( $219.5 \pm 92.6$  vs  $181.1 \pm 140.9$  N) ground reaction forces at impact did not differ after the implementation of the fatigue protocol ( $P > 0.05$ ). **Discussion** The results of the present study showed that fatigue did not affect kicking performance. Contrary results have been reported in the literature (Appriantono et al., 2006; Kellis et al., 2006). However, previous studies have examined male players and applied different protocols, thus making the comparisons difficult. The present study suggests that female players under fatigue conditions can perform a maximum kick as fast as before the game. **References** Abdul-Aziz R., Tan F. & Teh K. ## INTRAINDIVIDUAL BIOMECHANICAL VARIABILITY IN BACKHANDSPRING IN DIFFERENT LEVELS OF EXPERTISE

PENITENTE, G., THOMAS, L.S., MERNI, F.

SHEFFIELD HALLAM UNIVERSITY

**Introduction** Gymnastics is characterized by closed skills motor tasks that require consistent movement patterns with minimal variations. As movement variability decreases with practice (Shumway-Cook and Woollacott, 2007), repeated practice is largely used by gymnasts to obtain movement consistency. The hypothesis for this study was that movement variability decreases as level of expertise increases. Thus, the purpose was to compare intra-individual biomechanical variability in the execution of the back handspring on the floor between two female gymnasts at different competition levels. **Methods** Two female gymnasts volunteered in the study. The gymnasts competed respectively in pre-junior (L2) and junior (C2) categories. Kinetics data from a Kistler force platform (1000 Hz) of the dominant hand were collected during six trials of back handsprings for each gymnast. The hand contact time, average vertical force, impact peak, time to impact peak and impulse were compared between the gymnasts by using the Mann Whitney test. Intra-individual variability was calculated by using %RMSD. Results Average vertical force and impact peak resulted to be significantly different between the gymnasts. The intra-individual variability recorded were 13%L2 and 6%C2 for the hand contact time, 7%C2 and 2%L2 for average vertical force, 12%C2 and 5%L2 for impact peak, 18%C2 and 25%L2 for time to impact peak and 19%C2 and 5%L2 for the impulse. **Discussion** Lack of significant differences in temporal variables showed that coordination level was not improved at a higher level of expertise. Similar findings were obtained by a previous study focus on variability among baseball pitchers (Fleising et al, 2009). On the contrary, the significant differences found in kinetics measures in this study contrasted with the results reported by Fleising et al (2009). The significant difference in the impact peak could represent an increased risk of injuries for the pre-junior gymnast. The pre-junior gymnast had a greater intra-individual variability in all the variables in comparison to the junior gymnast with the exception of the time to impact peak. The variability that characterized the pre-junior gymnast's performance was a random variability caused by a reduced ability to control the task. The variability showed by the junior gymnast was a functional variability that represented a personal strategy used to complete the motor task (Barlett et al 2007). A better understanding of the biomechanical intra-variability associated with different level of expertise in closed skills sport can effectively contribute to accelerate the learning process and reduce the risk of injuries. **References** Bartlett R, Wheat J, Robins M. (2007). *Sports Biom* 6 (2), 224-243. Shumway-Cook A, Woollacott MH (2007). Fleising G, Chu Y. Weber A, Andrews J. (2009) *Sports Biom* 8(1) 10-21.

## STRIDE RATE AND RUNNING MECHANIC IN TRIATHLETES

MARTÍN CARO, C.

REY JUAN CARLOS UNIVERSITY AND OPTIMAL ENDURANCE TRAINING

**Introduction** The aim of our study is to assess relationship between the kinematic running variables in competition and the differences in these variables between low and high stride rate. **Methods** The work was conducted in competitive conditions with 17 triathletes (14 men and 3 women) of age group competitive level in Sprint and Olympic distance. The competition recording were held in a sagittal plane with a Canon digital camera to 25 Hz at the middle of the first running segment, using a reference system of 4-points, to obtain the kinematic parameters was used the Dartfish Connect 5.5 software, which allows make an analysis in two dimensions, calculating several variables relating to joint angles and distances. Running speed was calculated from the stride rate (SR) and stride length. The kinematic parameters were calculated in 5 key positions following the standards of Leskinen researches (2009) and our own standard: First contact with the ground, hip at the level of support, foot last contact with the ground, maximum knees separation and landing. We used the mechanical model of the human body of 14 segments. Pearson correlations were performed between each variable obtained from each triathlete. Also we studied the effect of SF on this variables, therefore following the observations of Daniels (2005) that good runners have a SR bigger than 90 cycles · min<sup>-1</sup>, the sample was divided in 2 groups, low frequency (LF; n=7; less than 90 cycles · min<sup>-1</sup>) and high frequency (HF; n=10; more than 90 cycles · min<sup>-1</sup>) assessing the average differences between both groups of each variable with an independent t-test. Statistical significance was established at 0.05 in both methods. **Results** We found significant correlations between speed and stride length ( $r = 0.96$ ), the maximum knees separation and speed ( $r = 0.89$ ), maximum knee flexion in support and knee angle landing ( $r = 0.82$ ), the strength index (propulsive distance / (stride length - landing distance)) and the knee angle in the recovery phase ( $r = 0.78$ ), anterior thigh angle to the vertical at the time of knees maximum separation and speed ( $r = 0.70$ ),  $p < 0.05$ . We found significant differences between HF and LF in vertical oscillation ( $6.11 \pm 1.66$  vs.  $7.84 \pm 2.29$  cm;  $t(15) = 1.81$ ;  $p < 0.05$ ), knee angle landing ( $158.99 \pm 4.90$  vs.  $163.83 \pm 5.54$ ;  $t(15) = 1.90$ ;  $p < 0.05$ ). **Discussion** Triathletes with a SR of more than 90 cycles · min<sup>-1</sup> have less vertical oscillation and knee angle landing. Also high values of knee angle at the time of first contact with the ground relate to high values in maximum knee flexion angle in support. The most correlated variables with running speed in competition are stride length and maximum knee separation. **References** Daniels, J. (2005). Daniels' Running formula. Leeds: Human kinetics. ## ELECTROMYOGRAPHIC ANALYSIS OF TRUNK MUSCLES DURING THE GOLF SWING PERFORMED WITH TWO DIFFERENT CLUBS

MARTA, S., SILVA, L., CORREIA, N., VAZ, J., BRUNO, P., PEZARAT-CORREIA, P.

FACULTY OF HUMAN KINETICS – TECHNICAL UNIVERSITY OF LISBON

**Objective:** The objective of this study was to compare the EMG patterns of trunk muscles during the different phases of the golf swing performed with two different clubs: a pitching wedge and a 4-iron club. **Methods:** Ten male golfers (handicap range 5-20) performed five swing shots with the pitching wedge and five swings with the 4-iron, in a random sequence. Surface electromyography (sEMG) was recorded from trunk muscles of both sides: rectus abdominis (RA), external (EO) and internal oblique (IO), erector spinae (ES) and gluteus maximus (GM). The sEMG signals were normalized using the sEMG of the maximal voluntary contraction (MVC) as reference. The average sEMG signal during each phase of the golf swing was determined. For delimitation of golf swing phases the swing was filmed with four high speed video cameras (100 Hz). Descriptive statistics were reported as mean  $\pm$  SD. Data were tested for normality with the Shapiro-Wilk test. Paired t-tests were performed to assess differences between club types (pitch and 4-iron). The significance level was set at 5%. **Results:** In most of the cases and phases trunk muscles showed higher mean values of EMG activation when the swing was performed with the 4-iron club. Nevertheless, significant statistical differences were found only in some cases. This is probably due to the high degree of variability between subjects. Significant differences ( $p = .026$ ) were only found during backswing phase on the left IO that showed a slight increase (1% MVC) in the level of activation when the swing was performed with the 4-iron. During Forward Swing phase,

significant differences between clubs were found, with higher levels of activity with the 4-iron club, for the left RA ( $p=.029$ ) and right IO ( $p=.014$ ) representing differences of 2 and 3% MVC, respectively. No significant differences between clubs were found for any studied muscle during the Acceleration phase. During Early Follow-Through the right ES was the only muscle that showed significant differences ( $p=.032$ ) between clubs, with an increase of 3% MVC when the swing was performed with the 4-iron club. During Late Follow-Through the IO showed significant differences between the two types of club in both sides, left ( $p=.003$ ) and right ( $p=.02$ ), with increases of 11% and 3% MVC, respectively, when the swing was performed with the 4-iron club. Significant increase was also observed in the left EO ( $p=0.04$ , 5% MVC) and in the left RA ( $p=0.009$ , 1% MVC). Conclusion: Comparing the EMG activation of trunk muscles during the golf swing performed with a pitching wedge and a 4-iron club, we can conclude that as a general tendency, trunk muscles were recruited with higher EMG activation when the swing was performed with the 4-iron club.

#### OP-SH04 Anticipation, Skill and Identity

##### ANTICIPATION OF DECEPTIVE SOCCER PENALTY KICKS

SMEETON, N.J.1, WILLIAMS, A.M.2,3

1 UNIVERSITY OF BRIGHTON, CHELSEA SCHOOL, UK 2 THE UNIVERSITY OF SYDNEY AND 3 LIVERPOOL JOHN MOORES UNIVERSITY, UK

**Introduction** When attempting to anticipate deceptive actions a different mode of visual perception may be evoked compared to making judgments on actions containing no deception. The use of exaggeration in the deceptive movement is thought to change visual perception from a 'direct' to a more 'indirect' or conscious mode of functioning (Jackson et al., 2005). This transformation is typically evidenced by a change from under to over estimation of confidence in the accuracy of the decision as well as a stronger correlation between confidence and accuracy (Runeson et al. (2000). **Methods** Skilled and less skilled soccer players were required to make anticipation judgments while watching filmed footage of deceptive, non-deceptive, and non-deceptive-exaggerated penalty kicks that were occluded at 5 time points ranging from 240 ms before ball foot contact to 80 ms after ball-foot contact in 80 ms intervals. Anticipation accuracy and decision confidence were measured. **Results** The levels of confidence were 3.2% and 10.3% greater than the actual accuracy scores when facing non-deceptive-exaggerated and deceptive penalty kicks respectively up to the -80 ms time point. This over confidence fell to 0.7% and -0.6% for the non-deceptive-exaggerated and deceptive penalty kicks respectively in the period up to ball foot contact. In addition, significant relationships between their confidence ratings and accuracy were found only in the less skilled players up to -80 ms before ball-foot contact in the deceptive ( $r=.59$ ) and non-deceptive-exaggerated ( $r=.54$ ) conditions, but not the non-deceptive condition ( $r=.28$ ). Significant relationships were found in the deceptive ( $r=.65$ ) and non-deceptive-exaggerated ( $r=.59$ ) and non-deceptive ( $r=.71$ ) conditions at the ball contact occlusion time point. **Discussion** This pattern of result suggests that exaggeration, which was common to both deceptive and non-deceptive-exaggerated conditions, caused the kicks to be perceived in a cue-base mode in the time period up to 80 ms before ball foot contact. However, the significant relationships in all three kick conditions as well as no evidence of under or over confidence at the ball foot contact time period suggests this effect is isolated to the -80 ms time period. **References** Jackson, R. C., Warren, S., & Abernethy, B. (2006). Anticipation skill and susceptibility to deceptive movement. *Acta Psychologica*, 123(3), 355-371. Runeson, S., Juslin, P., & Olsson, H. (2000). ##### DYNAMIC AND ECOLOGICAL IMPLICATIONS FOR SELF-REGULATION: USING MULTI-METHOD AND EMERGENT RE-SEARCH DURING A THREE-DAY ADVENTURE RACE

BUCHANAN, N.

UNIVERSITY OF THE WEST OF SCOTLAND

Buchanan, N.I., Ollis, S.I. 1: University of the West of Scotland (Hamilton, Scotland) **Introduction:** There is considerable desire to understand adaptability in sporting and performance domains (Hatano and Inagaki, 1986; Ollis et al., 2005). The importance of self-regulation, and its consequential ability to change and stabilize, in this topic area is key (Zimmerman and Cappillo, 2006; Karoly et al., 2005). Therefore, the aim of this study was to analyse the contributions of adaptability, transition, change, and regulative capability in a complex and real world domain. **Methods:** An exploratory case study methodology was adopted using mixed method design of a 3-day adventure race team ( $n=6$ ). The mixed methods were used in conjunction with emergent and flexible research principles (Yin, 1998; Wolcott, 1999). As such, the researcher and research assistants conducted a micro-ethnography of a three day mountain marathon and sailing adventure race which adopted video analysis, biofeedback, behaviour analysis, semi-structured interviews, field notes, focus groups and questionnaires. The analysis was conducted using interpretational paradigm over a two week period reviewing and sense-making all data. **Results:** The findings suggested the ability to adapt and regulate to such a challenging, complex and real-world event is dynamic, iterative and multi-faceted. Accordingly, results could only be offered in consideration to a model which was multi-disciplinary, multi-level and multi-phasic. Data was correlated to show a relationship towards a dynamic model of self-regulation. **Discussion:** In a real world and complex environment there is a tack to take a more real world systemic worldview of self-regulation. As such, present findings accord that self regulation and adaptability in complex, dynamic and challenging contexts have to be researched and applied with consideration to the synergy of self as a personal, relational and collective entity which affords alternating understandings at multiple time scales. Indeed, we propose that understanding self regulation and adaptability from the perspective of the complexity sciences may prove advantageous. With consideration to methodology, the adoption of the emergent and flexible research design was deemed as highly challenging, fruitful and fulfilling. **References:** Hatano, G., Inagaki, K. (1986). ## KINEMATIC PARAMETERS OF MODERN DANCE SKILLS THAT INFLUENCE AESTHETIC PERCEPTION IN NON-EXPERT OBSERVERS

TORRENTS, C.1, CASTAÑER, M.1, JOFRE, T.2, MOREY, G.2, REVERTER, F.3

1INEFC-UDL (LLEIDA-SPAIN) 2INESCOP (SPAIN) 3UB (BARCELONA, SPAIN)

**Introduction** Certain kinematic and biomechanical parameters can influence the subjective aesthetic perception of the modern dance audience. Neave et al. (2010) reported 11 movement variables in non-expert male dancers, showing a significant positive correlation with perceived dance quality. Using three-dimensional motion-capture technology the aim of the present study was to identify the kinematic parameters of expert dancers' movements that influence the subjective aesthetic perception of observers in relation to specific skills of modern dance. **Methods** Four experienced modern dancers performed three repetitions of four dance-related motor skills (turn, balance, jump and displacement) in a space measuring 3m x 4m x 2.5m. Retro-reflective markers were attached to defined locations of the dancers' anatomy, as defined by the PlugInGait marker set (VICON). This allowed us to obtain animated stick figures and to calculate several kinematic parameters. Motion was captured by a VICON-MX system (Oxford Metrics, Oxford) with ten cameras operating at 125 Hz. The PlugInGait calculations and custom-written MATLAB (The Mathworks Inc., Massachusetts) routines were used to obtain the parameters. The resulting 48 animations were observed by 100 participants, who judged their beauty using a semantic differential scale based on theories regarding the existence of an underlying general factor in aesthetic perception. The data were then analysed using a multiple factor analysis (MFA), working with data tables in which a set of individuals is described by several sets of variables. **Results** The MFA of the turning skill suggested that the maximum angular velocity of the pelvis around the Z (vertical) axis is the most influential parameter as regards achieving high beauty scores. The perception of beauty for the balance skill (arabesque) seems to be more affected by the opening angle of the legs, while for jumps the most influential variables are the height of the jump and variables related to the amplitude of the movement (such as the maximum motion amplitude of the centre of mass in the Z axis, or the maximum inclination of the body at the moment of maximum height). Beauty also seems to be mostly affected by the amplitude of the movement when it comes to appraising displacements. **Discussion** The overall results suggest that non-expert observers are influenced by the most basic characteristics of dance skills, such as the speed of turning, the height of jumps or the amplitude of movement. Subsequent studies will focus on detecting differences among expert observers about which relevant kinematic parameters may influence aesthetic judgement in modern dance. **References** Neave N, McCarty K, Freynik J, Caplan N, Hönekopp J & Fink B Biol. Lett. 2010

## A POSSIBLE EXPLANATION OF THE ANTICIPATION SKILL OF DEFENDERS IN A QUICK CHANGE OF RUNNING DIRECTION, BASED ON THE INVERTED PENDULUM MODEL

FUJII, K.1, SHINYA, M.2, YAMASHITA, D.1, ODA, S.1

1: KYOTO UNIVERSITY (KYOTO, JAPAN), 2: UNIVERSITY OF ALBERTA (ALBERTA, CANADA)

**Introduction** In 1-on-1 situations in a ballgame, defenders must anticipate and stop the advance of attackers. In this study, we first investigated when a defender is able to make a decision on an attacker's final running direction. Defenders' decision-making time occurred so early that the actual displacement of the attacker's centre of mass (CoM) is unlikely to be a relevant cue. Instead, we tested the hypothesis that defenders simulate the future trajectory of the attackers' CoM and make decisions based on the result of the simulation by using the inverted pendulum model (IPM). **Methods** Seven ballgame players participated in this study as attackers, and ten as defenders. The attackers performed a quick change of running direction, which was filmed head-on. To investigate when defenders were able to make a decision, the defenders watched attackers' motion on a life-size screen, and employed a whole body reaction. The defender's decision-making time was estimated by subtracting a simple choice reaction time from the reaction time. To test the hypothesis, the attacker's CoM and foot displacement were first captured (300 Hz). Then we created the software that calculated the future CoM trajectory, by substituting the position and velocity information of CoM and foot position, as initial values, into the equation of inverted pendulum motion. The software determined the timings of the relevant cue as the time of the initial values when estimating the CoM position was over the lateral threshold (IPM-based cue), or as the time when the actual lateral displacement of the CoM exceeded the threshold (CoM-based cue). In all timing analyses, 0 ms was defined as the foot contact of direction change by the attackers. **Results** The reaction time tasks demonstrated that the defenders made a decision at  $-340 \pm 26$  ms and reacted at  $-40 \pm 30$  ms. The simulation of the IPM revealed that the IPM-based determined time ( $-245 \pm 145$  ms) was earlier than the CoM-based determined time ( $110 \pm 52$  ms). Furthermore, the earlier a defender's decision-making time, the earlier was the IPM-based determined time (Spearman's  $\rho = .795$ ). **Discussion** First, the results of the reaction time tasks indicated that under real-time constraints, defenders could make decisions very early and could therefore stop the attackers' advance. Second, the hypothesis was supported. This suggested that defenders in a ballgame may need to look not only at attackers' CoM (approximated by trunk) but also at their feet. Finally, the strong correlation between the defender's decision-making and the IPM-based determination suggested that the defenders may make decisions by portraying the attackers as IPM.

## ATHLETIC IDENTITY IN ENGLISH PROFESSIONAL YOUTH TEAM FOOTBALLERS

MITCHELL, T., RICHARDSON, D., NESTI, M.S., LITTLEWOOD, M.A.

LIVERPOOL JOHN MOORES UNIVERSITY

**Athletic Identity in English professional youth team footballers** Mitchell, T.O, Richardson, D., Nesti, M.S. & Littlewood, M.A. **Research Institute for Sport & Exercise Sciences Liverpool John Moores University, UK** **Introduction** Athletes with a strong Athletic Identity may be more motivated and committed in their sporting endeavours (Brewer, Van Raalte & Linder, 1993). Conversely such a focus may render athletes with one-dimensional sense of self which may have negative psychological consequences e.g. experiences of discomfort when not training (Werthner and Orlick, 1986). Nesti (2004) and Nesti and Littlewood (2009) report that elite footballers with a multi-dimensional sense of identity possess a more solid base for the demonstration of their talent. The aim of this study is to identify levels of Athletic Identity in youth team footballers as a function of level of play, living arrangements & year of apprenticeship. **Method** One hundred and sixty eight youth team footballers from 12 professional football clubs across four professional leagues (Premier League, Championship, League 1 & League 2) completed the Athletic Identity Measurement Scale (AIMS) (Brewer & Cornelius, 2002). **Results** A one-way ANOVA and post hoc analyses with level of play as a function indicated no significant differences in total AIMS score. PL players reported significantly ( $p < 0.05$ ) higher levels of Exclusivity than L2 players. An independent sample t-test showed Y1 apprentices possessed significantly ( $p < 0.05$ ) higher levels of Social Identity than Y2's. Those living away from home displayed significantly ( $p < 0.05$ ) higher levels of Exclusivity than those living at home. **Discussion** Level of play does not appear to be a factor in the development of AI suggesting the working environment may be more on an influence in AI development. Year of apprenticeship affects Social Identity with a decrease in year two

possibly due perceived difficulties in gaining professional status. Living arrangements affect levels of Exclusivity suggesting that those living away may develop a more one-dimensional sense of self. ### OP-PM50 Physiology: Reproductive Hormones

#### SEX DIFFERENCES IN FUNCTIONAL HAMSTRING/QUADRICEPS RATIO AND THE EFFECT OF JOINT ANGLE AND MOVEMENT VELOCITY

DE STE CROIX, M., ELNAGAR, Y.O., JAMES, D.V.B.

UNIVERSITY OF GLOUCESTERSHIRE

SEX DIFFERENCES IN FUNCTIONAL HAMSTRING/QUADRICEPS RATIO AND THE EFFECT OF JOINT ANGLE AND MOVEMENT VELOCITY De Ste Croix, M.B.A; Elnagar, Y.O; and James, D.V.B. University Of Gloucestershire, Department of Sport and Exercise, Gloucester, UK. Introduction Females are at greater relative risk of non-contact ACL injury compared with males (Faude et al., 2005). Dynamic knee stability is an essential component required to reduce relative risk of injury to the knee joint. The ability of the hamstrings to co-contract eccentrically to counter the torque produced concentrically by the quadriceps action during knee extension is important in stabilising the knee. The purpose of the present study was to explore sex differences in the functional hamstring to quadriceps ratio (F-H/Q ratio) whilst taking into account joint angle and movement velocity. Methods Participants (n = 110; 55 males and 55 females) provided written informed consent to participate in the study. Prone isokinetic torque was determined sequentially at velocities of 60, 120, 240°/s with the hip flexed at 10°. Knee joint range of movement was 90° with 0° determined as full volitional extension. Torque was determined from concentric (CON) actions using CON/CON cycles followed by eccentric (ECC) flexion cycles. Torque was gravity corrected and filtered to only include constant velocity periods. F-H/Q ratio was determined at joint angles of 15, 30, 45° and the angle of peak torque (PT) for each velocity. A 2 (sex) x 3 (velocity) x 4 (joint angle) ANOVA was performed with subsequent post hoc analysis using Bonferroni correction. Results F-H/Q ratio ranged from 55% to 114% across joint angles and velocities. Significant main effects ( $p < 0.05$ ) for both joint angle and velocity were observed, with a greater F-H/Q ratio closer to full knee extension and at faster velocities. A significant main effect ( $p < 0.05$ ) for sex was demonstrated with the F-H/Q ratio higher in males compared with females at all joint angles and movement velocities. The difference between males and females increased with increasing joint angular velocity. Discussion Irrespective of sex, the F-H/Q ratio increases with joint extension and velocity to improve knee stability thereby counteracting high shear forces. The lower F-H/Q ratio in females and the increasing sex difference as velocity increases, along with the lower F-H/Q ratio close to full knee extension, predisposes females to increased knee injury risk due to impaired dynamic knee stability. #### THE ANABOLIC STEROID METHANDIENONE TARGETS THE HYPOTHALAMIC-PITUITARY-TESTICULAR AXIS AND MYOSTATIN SIGNALLING IN A RAT TRAINING MODEL

MOSLER, S.1, PANKRATZ, C.1, SEYFRIED, A.1, PIECHOTTA, M.2, DIEL, P.1

1: GERMAN SPORT UNIVERSITY COLOGNE; 2: UNIVERSITY OF VETERINARY MEDICINE HANNOVER

Introduction There is increasing evidence that the biological activity of Myostatin (MSTN), a member of the transforming growth factor- $\beta$  family of proteins (TGF- $\beta$ ) is affected by training but also anabolic steroids. To further study molecular mechanisms of the training induced adaptation of skeletal muscle, the aim of this study was to analyse effects of the frequently abused anabolic steroid methandienone (Md) on the hypothalamic-pituitary-testicular axis and on MSTN signalling in an animal model simulating the situation of abusing athletes. Methods Male Wistar rats performed a 4-week treadmill-based exercise protocol in combination with Md treatment. Effects on the hypothalamic-pituitary-testicular axis and androgen sensitive tissues were determined and correlated to the expression of members of the MSTN signalling cascade (MSTN, MyoD, Smad7 and Follistatin) in gastrocnemius and soleus muscle. Results Treatment with Md resulted in a significant stimulation of the weight of levator ani muscle. This effect was enforced by training. Prostate and seminal vesicle weights decreased after Md treatment. Hormone concentrations of LH and testosterone were significantly decreased after Md treatment. Interestingly also training decreased serum testosterone, while no effects on LH and FSH could be observed. MSTN, Smad7 and MyoD mRNA expression in gastrocnemius muscle were reduced by training but not after Md treatment. In contrast the mRNA level of the MSTN inhibitor Follistatin (FST) was significantly reduced in gastrocnemius muscle by training and Md. In soleus muscle MSTN and FST mRNA expression was not affected by training but it was increased after Md treatment in combination with training. No changes of FST protein expression in serum were detected. Conclusion In summary our data demonstrate that Md treatment of intact rats results in anabolic effects which are increased by training. These anabolic effects correlate to changes in the expression patterns of genes involved in MSTN signalling in the soleus and gastrocnemius muscle but do not effect FST concentrations in the serum. In contrast Md treatment decreased the weight of androgen sensitive tissues like the prostate. Our data provide evidence that this effect is caused by a suppression of endogenous testosterone synthesis via the hypothalamic-pituitary-testicular axis. These observations provide insights into the molecular mechanisms of skeletal muscle adaptation and may be helpful to develop new test systems to detect the abuse of anabolic steroids.

### THE EFFECT OF ANDROGEN DEPRIVATION THERAPY AND STRENGTH TRAINING ON HEAT SHOCK PROTEINS IN MUSCLE IN ADT TREATED PROSTATE CANCER PATIENTS.

KIRKEGAARD, C., NILSEN, T.S., THORSEN, L., FOSSÅ, S., RAASTAD, T.  
NORWEGIAN SCHOOL OF SPORT SCIENCES

Introduction and aim Prostate cancer growth is stimulated by the presence of androgens (testosterone). Therefore androgen deprivation therapy (ADT) is an effective treatment in these patients. However, testosterone is involved in regulation of several processes in skeletal muscle, and a reduction of muscle mass in ADT treated patients has been reported (1). Testosterone also regulates heat shock protein synthesis (2), which is involved in cellular responses to exercise induced stress, and possibly daily maintenance, in skeletal muscle. Consequently, the aim of this part of the Physical Exercise and Prostate Cancer study (PEPC) was to investigate the effect of ADT alone or combined with strength training on the content of heat shock proteins in m. vastus lateralis. Methods PEPC is a randomized controlled trial with a strength training group (STG) (n=10) and a control group (CG) (n=10), following standard care, in ADT treated patients. After six to nine months on ADT the STG performed three strength-training sessions per week, where two of the sessions were supervised and consisted of 1 to 3 6-10 RM sets, and one sub maximal session. The training consisted of squat, leg press, standing calf raises, leg curl, leg extension, chest press, seated rowing, shoulder press and biceps curl. Muscle biopsies were obtained pre-intervention assessment and after the 16 weeks of intervention (post-intervention assessment). The biopsies were homogenized and divided into cytosolic, cytoskeletal, nuclear and membrane fractions. The homogenate were then analyzed by Western blot using a monoclonal antibody against HSP 70 and a monoclonal antibody against  $\alpha$ B-Crystallin. Results Preliminary results from 8 patients (4+4) indicate a reduction of both HSP70 and  $\alpha$ B-Crystallin in the membrane fraction in STG, but no alterations in the cytosolic fraction. Final results will include analysis of biopsies from 10 and 9 subjects in the CG and STG, respectively. Discussion An increase in HSP levels has been shown after strength training in young subjects. However, a decreased expression of HSP70, and no change in  $\alpha$ B-crystallin, has been reported in the cytosolic fraction, leaving the membrane fraction unchanged, in elderly following strength training (3). Further analysis will reveal whether the initial levels of HSP, and response to strength training, differs between ADT treated patients and healthy controls. Reference List 1. Boxer et al. ### EFFECTS OF QUASI-FOLLICULAR AND QUASI-LUTEAL PHASE-BASED ENDURANCE TRAINING ON MUSCLE CELL PARAMETERS IN SUBJECTS WITH ORAL CONTRACEPTION

HAN, A.1, SUNG, E.1, HINRICHS, T.1, VORGERD, M.2, PLATEN, P.1  
RUHR-UNIVERSITY BOCHUM

Purpose: : Monophasic oral contraceptives (OC) contain fixed doses of estrogen (E) and progestogen (P) which are taken for 21 days, followed by 7 days of OC break, leading to more or less constant concentrations of blood estradiol and progesterone during the first 21 days. The regulation of other interacting hormones like IGF-1, testosterone and DHEAs, all of them possible anabolic hormones on the level of the muscular cell during endurance training, is not clear so far in OC users. Therefore, we investigated effects of "quasi follicular phase-based" versus "quasi luteal phase-based" endurance training on fiber composition, fiber diameter and cell nuclei to fiber ratio of skeletal muscle in OC users. Methods: Five healthy untrained or moderately trained women using OC completed endurance training on a bicycle ergometer for each leg for 3 menstrual cycles (12 weeks). The subjects trained one leg mainly in quasi-follicular phase (qFT) and the other in quasi-luteal phase (qLT). Muscle fiber composition (F%no: relative fiber number, F%area: relative fiber area), muscle fiber diameter (Fdm) and cell nuclei to fiber ratio (N/F) were determined in skeletal muscle biopsy samples of both legs (m. vastus lateralis) prior to and after training intervention using histochemical analysis (ATPase and HE staining). Results: After endurance training intervention, mean values of F%no and F%area showed reductions (by  $6.9 \pm 11.5\%$  and  $6.6 \pm 10.6\%$ ) in type I fiber after qFT whereas there were increases (by  $4.0 \pm 5.9\%$  and  $4.4 \pm 9.4\%$ ) in type I fibers after qLT. However, deviation of values was large among the 5 subjects. We could not demonstrate any relevant changes in Fdm of type I and type II fibers neither after qFT ( $-0.5 \pm 4.3$  and  $-1.0 \pm 5.0$ ) nor after qLT ( $+0.2 \pm 6.4$  and  $-0.5 \pm 6.4$ ). N/F also showed no relevant change after qFT ( $+0.4 \pm 0.4$ ) and qLT ( $+0.1 \pm 0.1$ ). Conclusions: Within a small sample of 5 subjects, we were not able to demonstrate any relevant differences between the two endurance training modes concerning adaptation of skeletal muscle. Further studies in larger samples will have to confirm this finding, which might be explainable by the artificially constant hormone levels in OC users. The confirmation of this finding would suggest that untrained or moderately trained OC users could perform endurance training independently from the phases of menstrual cycle.

### THE EFFECT OF ANABOLIC STEROIDS ON MYONUCLEAR NUMBER

EGNER, I.M., BRUUSGAARD, J.C., GUNDERSEN, K.  
THE UNIVERSITY OF OSLO

Introduction Until recently, it was believed that myonuclear number was reduced under atrophy conditions. We have shown that myonuclear number is not reduced after denervation or inactivity in mice (Bruusgaard, 2010). Furthermore, since the effects of testosterone on skeletal muscle are mediated via androgen receptors expressed both in myonuclei and in the nuclei of satellite cells (Kadi, 2008), we wanted to examine if the use of anabolic steroids would lead to an increased number of myonuclei as well as investigate if these newly acquired myonuclei are permanent. Methods Pellet containing testosterone propionate (TP) (0.005 mg/g/day) or placebo were operated into the neck of female NMRI mice (20-30g). In order to overload the m. soleus, 2/3 of the m. gastrocnemius was excised. For in vivo nuclear imaging of nuclei, single soleus fibers were injected with 5'-FITC-labelled phosphorothioated oligonucleotides as described previously (Bruusgaard, 2003). Fiber segments of 250-1000 mm were analyzed as described before (Bruusgaard, 2010). For fiber area measurements and counting of nuclei, cryo-sections were stained with anti-dystrophin and DAPI. In the first set of experiments mice were randomly assigned into four groups: 1) Placebo, 2) TP, 3) Placebo overload, 4) TP overload. After 14 days the soleus muscle were analyzed first with in vivo imaging of single fibers and then the soleus muscle were excised and frozen for immunohistochemical analysis. Results The number of nuclei increased with 28%, 22% and 67% compared to placebo in TP, placebo overload and TP overload respectively (n=3). The fiber cross-sectional area increased with 28%, 22% and 62% compared to placebo in TP, placebo overload and TP overload, respectively (n=3). Discussion Our data show that use of anabolic steroids during overload hypertrophy leads to an increase in fiber size and myonuclear number more extensive than TP treatment only or overload only. Anabolic steroid treatment itself leads to an increase in fiber cross-sectional area and a higher number of myonuclei than overload induced hypertrophy. The use of anabolic steroids is widespread among athletes, and if the induced changes in skeletal muscle are permanent or long-lasting it might have consequences for the

exclusion period given to doping offenders. References Bruusgaard JC, Johansen IB, Egner IM, Rana ZA, Gundersen K. (2010). *Proc Natl Acad Sci*, 107(34), 15111-6. ### **REPEATED MUSCLE BIOPSIES THROUGH A SINGLE SKIN INCISION DO NOT ELICIT MUSCLE SIGNALING, BUT IL-6 MRNA AND STAT3 PHOSPHORYLATION INCREASE IN INJURED MUSCLE.**

GUADALUPE GRAU, A., GÓMEZ-CABRERA, M.C., PÓNCE-GONZÁLEZ, J.G., MARTINEZ-BELLO, V.E., GUERRA, B., FEIJOO, D., SANTANA, A., SEBASTIA, V., VIÑA, J., CALBET, J.A.L.

UNIVERSITY OF LAS PALMAS DE GRAN CANARIA, UNIVERSITY OF VALENCIA.

To determine if muscle biopsies can be repeated using a single small (5-6 mm) skin incision without inducing immediate MAPK activation or inflammation in the non-injured areas, the phosphorylation of ERK1/2, p38-MAPK and c-Jun NH2-terminal kinases (JNKs), IκBα, IKKα, and signal transducer and activator of transcription 3 (STAT3) was examined concurrent with IL-6 mRNA in six muscle biopsies obtained from the vastus lateralis of five men. Four biopsies were obtained through the same incision (5-6 mm) from the right leg (taken at 0, 30, 123 and 126 minutes) and another two each from new incisions performed in the left leg (at 31 and 120 minutes), while the subjects rested supine. The first three biopsies from the right leg were taken approximately 3 cm apart from pre-biopsied areas. The last biopsy was obtained from the same point from which the second biopsy was sampled. The three biopsies performed through the same skin incision from non-injured muscle areas showed similar levels of ERK1/2, p38-MAPK, JNK, IKKα, IκBα and STAT3 phosphorylation, and similar IL-6 mRNA content. There were no significant differences in the levels of ERK1/2, p38-MAPK, JNK, IKKα, and IκBα phosphorylation between the mean of the three biopsies obtained from the same incision and the sixth biopsy obtained from an injured area. STAT3 phosphorylation was increased by approximately 3.5-fold in the sixth biopsy compared to the mean the three biopsies obtained from the same incision ( $P < 0.05$ ) and IL-6 mRNA content by 1.8-fold ( $P < 0.05$ ). In summary, repeated muscle biopsies can be performed through a single 5-6 mm skin incision without eliciting muscle signaling through cascades responding to cellular stress, inflammation or muscle damage. STAT3 phosphorylation is an early event in the healing response to muscle injury, likely mediated by the autocrine production of IL-6. Acknowledgements This study was supported by grants from the Ministerio de Educación y Ciencia (DEP2010-21866 and FEDER) and DPS2008-06968, SAF2010-19498, ISCIII2006-RED13-027

### **IS-PM06 Novel Quantitative Approaches to Combat Doping**

#### **RANDOMIZED RESPONSE ESTIMATES FOR DOPING AND ILLICIT DRUG USE IN ELITE ATHLETES**

STRIEGEL, H., SIMON, P., NIESS, A., ULRICH, R.

UNIVERSITY OF TÜBINGEN

Randomized response estimates for doping and illicit drug use in elite athletes Introduction: In contrast to fitness sports, there are no reliable estimates for the percentage of unknown cases of doping and illicit drug use in elite sports. Due to the familial atmosphere in elite sports, it is problematic to get reliable epidemiological estimates of deviant or illicit behaviour questionnaires and surveys. Methods: 1394 athletes were questioned using an anonymous questionnaire (SQ), and 480 athletes were interviewed using randomized response technique (RRT). All athletes were subject to doping controls as members or junior members of their respective national teams. A two-sided z-test was used to compare the SQ and RRT results with the respective official German NADA data on the prevalence of doping. Results: Official doping tests only show 0.81% ( $n = 25,437$ ; 95% CI: 0.70–0.92%) positive test results, while RRT shows 6.8% ( $n = 480$ ; 95% CI: 2.7–10.9%) positive responses to having practiced doping ( $z = 2.91$ ,  $p = 0.004$ ). 7% illicit drug use was shown by both SQ and RRT, but due to the fear of being recognized by their answers SQ failed to indicate a realistic prevalence of doping (0.20%; 95% CI: 0.02–0.74%). Discussion: The data from official doping tests underestimate the true prevalence of doping in elite sports. In our study, we found an 8-fold higher doping prevalence using RRT compared to the results of official doping tests. Therefore, implementing RRT before and after anti-doping measures could be a promising method for evaluating the effectiveness of anti-doping programs.

#### **DETECTING NEW SUBSTANCES AND METHODS OF DOPING USING BIOANALYTICAL APPROACHES**

THEVIS, M.

GERMAN SPORT UNIVERSITY COLOGNE

The dynamic nature of the pharmaceutical market and the continuously increasing number of emerging drugs represents a considerable challenge to sports drug testing authorities and laboratories. Besides new structural and, thus, physicochemical properties to be considered in analytical methods, their metabolism to urinary degradation products is commonly unknown. In the presentation, new drug candidates potentially or evidently representing a threat to the integrity of sport will be presented, and options to measure and determine the active compound as well as metabolites will be discussed.

#### **LONG-TERM AND DIRECT DETECTION OF MUSCLE-DIRECTED GENE TRANSFER IN CONVENTIONAL WHOLE BLOOD SAMPLES**

SIMON, P.

JOHANNES GUTENBERG-UNIVERSITY

The abuse of gene transfer technology in sport is perceived as an upcoming danger for elite sports. So called 'gene doping' using sophisticated gene transfer technology delivering human DNA sequences for the purpose of doping is supposed to be undetectable. This talk will present a molecular biological approach that is able to directly detect transgenic human DNA derived from gene doping with high specificity and ultra-high sensitivity on the single molecule level. The technique is based on a novel single copy PCR procedure called spiPCR and has so far been optimized for the inexpensive and robust detection of gene transfer for all relevant splice variants of IGF1, VEGFa, VEGFc, hGH, FST and EPO in conventional whole blood samples. The procedure is an effective tool to monitor the faith of tran-

scripts within the body following gene therapeutic applications. The technical features of the procedure, its potential applicability for doping analysis and its potential pitfalls are discussed.

### OP-BN02 Sports Biomechanics 1

#### THE EFFECT OF DIFFERENT CLIMBING SPECIFIC HOLDS ON FINGER FORCES AND FORCE SHARING AMONG THE FINGERS

WERNER, I., GEBERT, W.

*INSTITUTE OF SPORT SCIENCE*

**Aim of the study** The decrease of particular finger strength when acting with two or more fingers at the same time and force sharing among fingers has been studied for a long time. Referring to sports climbing Quaine et al. (2003) simulated climbing specific finger postures measuring the vertical force when pressing on a force platform or crushing the fingers in a vertical position (Vigouroux et al. 2008). In order to study finger forces in a climbing specific context an apparatus was constructed offering the possibility to compare different shapes of holds including the adjustment to finger length. The aim of this study was to compare maximal finger forces on different holds arranged in a straight-line position or adjusted to finger length. **Methods** Finger forces were measured for each finger separately with strain gauges orthogonal to the support surface of the finger tips with a measurement accuracy of 0.2 N. Holds were wooden and covered with synthetic resin and quartz sand. Twelve climbers (average age 25y, 5.11c level on sight) volunteered for the study. Subjects sat on a chair, the measure device fixed between the axilla and the finger tips. Subjects pulled twice with maximal effort. The best trial was analysed. Retest-reliability approved to be high ( $r > 0.90$  each) in all combinations of holds and fingers acting. Maximal finger forces and force sharing was observed when acting with the middle finger, index finger and ring finger in various combinations on a ledge (crimp grip), a convex hold (slope grip) and a concave hold (slope grip) with and without adjustment to finger length. Analysis of repeated measures (SPSS 15.0,  $p < 0.05$ ) was calculated to detect differences. **Results** The highest values of finger forces were observed for the concave hold. The middle finger revealed strongest. Acting with the index finger the middle finger achieved about 90% of its maximum force, acting with the ring finger only 75%, combining all three fingers about 70%. The sum of force production differed significantly in the single maximum condition, straight-line hold position (altogether) and adjusted hold position (altogether). In the latter the force of the middle finger increased, the force of the index finger and ring finger decreased compared to the straight-line condition. Percentage of maximum individual finger force production did not differ whether the holds were adjusted to finger length or not, but differed significantly between the three forms of holds (crimp grip  $> 90\%$ , slope grip 75%). **Discussion** Crimp grip seems to activate a higher percentage of maximal strength. This is likely due to the unstable finger position in the one finger act. Holds adjusted to finger length showed no advantage to force production because of limitations in muscle excitation. **References** Quaine, F., Vigouroux, L., Martin, L. #### LUMBO-PELVIC LATERAL FLEXION MOTION AND KINETICS DURING FAST BOWLING IN CRICKET

CREWE, H.1, CAMPBELL, A.2, ELLIOTT, B.1, ALDERSON, J.1

1: UNIVERSITY OF WESTERN AUSTRALIA (PERTH, AUSTRALIA), 2: CURTIN UNIVERSITY OF TECHNOLOGY (PERTH, AUSTRALIA)

**Introduction** Stress fractures of the lumbar pars interarticularis (spondylolysis) are common in sports involving repetitive flexion-extension and rotation of the trunk[1], such as fast bowling in cricket. Recent work has indicated that lateral flexion, too, places significant stress on the pars[2] and that fast bowlers move the trunk through an extreme range of lateral flexion towards the side contralateral to the dominant arm[3]. It has been found that spondylolyses occur more frequently on the contralateral side of the vertebra in fast bowlers[4] and that the quadratus lumborum muscle, a lateral flexor of the lumbar spine, is often enlarged on the bowler's dominant side[5]. **Methods** The current study aimed to investigate lumbo-pelvic lateral flexion motion and kinetics in 14 right-arm fast bowlers (mean age 16.5 years), using a novel biomechanical model. **Results** During bowling, each subject reached a peak left lateral flexion angle that was greater than the peak angle measured during a standing maximum active range of motion trial (mean  $8.6^\circ \pm 2.7$ ). Large left lateral flexion moments ( $13.5 \text{ Nm.kg}^{-1} \cdot \text{m}^{-1} \pm 2.6$ ) and peak power ( $-7090.1 \text{ W} \pm 3983.9$ ) were recorded. **Discussion** Extreme lumbo-pelvic lateral flexion and large moments during the delivery stride may contribute significantly to the loading of the pars interarticularis and therefore the high incidence of spondylolysis in fast bowlers. Negative joint power in right-arm bowlers indicates that left lateral flexion of the lumbar segment relative to the pelvis is a controlled motion resisted by the right lateral flexor muscles. This is the first study to provide a potential biomechanical mechanism for the increased cross-sectional area of the dominant side quadratus lumborum seen in many fast bowlers and is part of a larger prospective trial that will examine the relationship between bowling technique, lumbo-pelvic biomechanics and injury. **REFERENCES** 1. #### THE EFFECT OF Q FACTOR ON CYCLING PERFORMANCE

DISLEY, B.X., LI, F.X.

*UNIVERSITY OF BIRMINGHAM*

**Introduction** The term Q Factor on a bicycle describes the horizontal width between pedals, measured from the outside face of the crank, to the corresponding outside face on the opposite crank. The Q Factor of a crank determines where the foot is laterally positioned throughout the pedal stroke. Due to manufacturing constraints, no production bicycle has a Q Factor lower than 135mm and a typical Q Factor ranges from ~150mm for a road bicycle, up to ~180mm for a mountain bicycle. In the past, a number of world champion cyclists have used custom made bicycles with narrow Q Factors in order to improve performance. One of the rationales for this strategy is that

the pedaling action would be more efficient, as force to the pedal would be applied closer to the plane of the crank. To date, there have been no scientific studies that explore the effect of manipulating Q Factor and its effect upon the cyclist. The aim of this study is to determine whether narrowing the Q Factor has a beneficial effect upon cycling performance variables and muscular activation. Methods 13 trained cyclists (6 male, 7 female; Age  $22.5 \pm 5.2$ ;  $\text{VO}_{2\text{max}}$   $56.7 \text{ ml.kg.min}^{-1} \pm 5.0$ ) volunteered for the study. Subjects pedaled at 60% of peak power output (PPO) for periods of 5min at 90 revolutions per minute (rpm), using Q Factors of 90, 120, 150 and 180mm (q90, q120, q150, q180). Each Q Factor was used twice for a total of 8 stages. Power output and expired gas data were collected and muscular activity data of the gastrocnemius (GM), tibialis anterior (TA), vastus medialis (VM) and vastus lateralis (VL) were measured using surface EMG sensors. Gross mechanical efficiency (GME) was calculated from the expired gas and power output data, and root mean square (RMS) muscular activity data were calculated over a time period of 30 pedal cycles during each stage. Results There was an overall significant difference for GME ( $F(1,3)=9.19$ ,  $p=.001$ , effect size  $=.43$ ). Post hoc comparison showed that GME for q90 was significantly higher (19.5%) than q150 and q180 (18.9 and 19.0%). All subjects reported a dislike of q180, and preferred either q120 or q90. There was no significant difference in RMS muscular activity of the GM, TA, VM and VL between the different Q Factors. Discussion The aim of this study was to explore the effect of Q Factor on cycling performance at submaximal intensity. The data show that narrower Q Factors (q90 and q120) result in higher GME than wider Q factors (q150 and q180), supporting the hypothesis. However, the level of muscular activation between Q Factors in the muscles analysed (GM, TA, VM and VL) did not change. Therefore, the increase in GME with narrower Q Factors may be due to a) a change in activation of stabilising muscles (besides those measured in this experiment), and/or b) a more optimal application of force during the pedal stroke.

## PEDALING TECHNIQUE AND ENERGY COST IN CYCLING

LEIRDAL, S., ETTEMA, G.

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY, TRONDHEIM

Introduction: Because cycling is an extreme endurance sport, energy saving and therefore efficiency is of importance for performance. It is generally believed that gross efficiency (GE) is affected by pedaling technique. A measurement of pedaling technique has traditionally been done using force effectiveness ratio (FE; ratio of effective force and total force). The aim of the present study was to investigate the relationship among GE, FE, and a new technique parameter, dead center size (DC) in competitive cyclists. Methods: Twenty-one competitive cyclists cycled for 10 min at approximately 80%  $\text{VO}_{2\text{max}}$  at a racer bike on a roller (simulating free cycling) at a freely chosen cadence (FCC). GE was calculated using oxygen consumption (Jaeger Oxycon Pro). FE and DC were calculated using propulsive force recordings from 2D force cells (Revere) mounted in the pedals and 3D kinematics (Pro-reflex). The lowest work rate (average of top and bottom dead center work rate) divided by the average work rate was defined as DC. Thus, this is a parameter describing the evenness of work rate generation (100% indicates a perfect circular work rate generation whereas 0 % indicates that the work rate at the dead center equals zero). Results: Mean work rate was 279 W, mean FCC was 93.1 rpm, and mean GE was 21.7%. FE was 0.47 and 0.79 after correction for inertial forces; DC was 27.3% and 25.7%, respectively. DC was not affected by inertial forces and size correlated better with GE ( $r = 0.75$ ) than with the FE ( $r = 0.50$ ). Multiple regressions revealed that DC was the only significant ( $P = 0.001$ ) predictor for GE. Interestingly, DC and FE did not correlate with each other. Discussion: For these cyclists DC is a parameter more closely related to energy cost than FE when cycling at FCC on a regular racing bike. Generating power evenly around the whole pedal revolution may be an energy saving trait, which is essentially different from applying forces effectively (FE). DC is not affected by inertial forces and also therefore may be a better measure than FE. However, preliminary results from another study using an ergometer (instead of a regular bicycle) at three cadences around FCC do not replicate these findings. Future research should be directed toward the mechanisms behind DC, how DC is affected by cadence and work rate and if it differentiates between cyclists at different performance levels.

## MODELLING THE TRAINING-PERFORMANCE RELATIONSHIP IN ELITE SWIMMERS

PFEIFFER, M., FUHRMANN, S.

TECHNICAL UNIVERSITY OF MUNICH (TUM), UNIVERSITY OF BAYREUTH

Introduction Mujika et al. (1996) and Hellard et al. (2006) used a mathematical model, original proposed by Banister (1991), to quantify the training and performance relationship of elite swimmers. Considering alternative methods because of unsatisfactory results in goodness of fit, Hellard et al. (2006) referred to the PerformancePotential-Model (PerPot), a dynamic model developed by Perl (2001). The PerPot helps to simulate the relationship between training and performance by using a state-event-model with adaptive delays. In training studies PerPot showed better results for model fit and prediction accuracy (Pfeiffer, 2008). We intend to determine whether PerPot can be used to validly analyse the training effects on performance in elite swimmers. Methods Six national and international level German swimmers (S1 to S7) were studied during a 12-week period. All training performed in water and dry-land was quantified daily according to Mujika et al (1996). In addition, a semi-tethered swimming test (20m without start) consisting of three repetitions (resistance increased trial by trial) was conducted to determine the swimming performance (mean velocity). To model the training-performance relationship the PerPot was used. Mean relative deviation (RD), Intraclass Correlation Coefficient (ICC) and Coefficient of Determination ( $R^2$ ) between modelled and real performances were calculated for each subject to estimate model goodness of fit. Results The following results could be achieved: S1 (N=15, RD=1.7%, ICC=.83,  $R^2 = .99$ ), S2 (N=10, RD=1.1%, ICC=.80,  $R^2 = .99$ ), S3 (N=10, RD=1.0%, ICC=.80,  $R^2 = .99$ ), S4 (N=9, RD=2.5%, ICC=.68,  $R^2 = .99$ ), S5 (N=10, RD=1.0%, ICC=.55,  $R^2 = .99$ ), S6 (N=10, RD=2.3%, ICC=.51,  $R^2 = .99$ ). Discussion Our findings show considerably better results for model fit as reported e.g. by Mujika et al. (1996) and Hellard et al. (2006). The results confirm that PerPot could successfully model the training effect on performance in middle-term adaptation. References Banister, E. W. (1991). Modeling elite athletic performance. In H. J. ### OP-PM03 Brain and Exercise

#### MOTOR AND PREFRONTAL CORTEX OXYGENATION EVALUATED BY NIRS DURING CONSTANT STRENUOUS CYCLING EXERCISE

BOURDILLON, N., DEROSIÈRE, G., VAUCHER, M., PERREY, S.

UNIVERSITÉ MONTPELLIER 1

**Introduction** Strenuous physical exercise, involving large muscle masses, is known to stress the oxygen transport system and may present significant threat to cerebral oxygenation patterns (Subudhi et al.). Regions of the brain that regulate the central motor drive should cope with fatigue development during such challenging exercises. To date, cerebral oxygenation adaptation patterns during prolonged strenuous exercise, over multiple brain regions, are not known (Rooks et al.). Therefore, the aim of this study was to investigate the cerebral and muscle oxygenation time courses during a constant strenuous cycling exercise. We hypothesized that dissociation occurs between cerebral and muscle oxygenation in order to maintain constant power output. **Methods** Ten healthy male subjects participated on two separate days. On the first day, they performed an incremental exercise test on a braked cycle ergometer to determine maximal oxygen consumption (VO<sub>2</sub>max, 30W/min until exhaustion). Gas exchanges at the mouth were monitored using a metabograph (ZAN680, Oberthulba, Germany) and cardiac output (Qc) was continuously measured throughout the tests via thoracic bio-impedance (Physioflow PF-05, Manatec Biomédical, Macheren, France). At least 24h later, subjects underwent a constant cycling exercise for 20min at an intensity based on the 30% difference between the first ventilatory threshold and VO<sub>2</sub>max. In addition to the apparatus described earlier, subjects were instrumented with several pairs of fNIRS optical probes (Oxymon Mark III, Artinis, The Netherlands) to monitor oxygenation levels in cerebral (left motor and prefrontal cortices) and muscle (right vastus lateralis) tissues. **Results** All subjects maintained the required intensity (240 ±40W) for 20 minutes. Mean VO<sub>2</sub> at steady state was 86 ±7% of VO<sub>2</sub>max (50 ±6ml/min/kg) and mean Qc at steady state was 94% of Qcmax (26 ±6l/min). Relative oxyhemoglobin increased both in the prefrontal cortex (+38.6 ±6.5μM) and in the motor cortex (+15.7 ±5.2μM) while a classical activation pattern was found for the vastus lateralis oxygenation dynamics. Time to plateau in oxy- and deoxyhemoglobin concentration changes in the cortical areas was 4 to 6 min, while at the muscular level; the plateau was reached earlier (2 to 4 min) as well as for VO<sub>2</sub> steady state achievement. **Discussion** These particular time courses suggest that cortex hemodynamics progressively shift during strenuous whole body exercise in order to maintain constant muscle output. The nonparallel changes in the signals between the muscle and the brain suggest a decoupling of the two signals which may be underlain by neural mechanisms adapting to muscle fatigue. #### EFFECTS OF ACUTE EXERCISE ON CORTICAL BRAIN ACTIVITY AND COGNITIVE PERFORMANCE IN 5-YEAR OLD CHILDREN

MIERAU, A.1, HENSE, A.2, HENSE, J.2, HÜLSDÜNKER, T.1, MIERAU, J.1, ZIRKEL, V.2, STRÜDER, H.K.1

1: GERMAN SPORT UNIVERSITY COLOGNE, INSTITUTE OF MOVEMENT AND NEUROSCIENCES (COLOGNE, GERMANY), 2: CHILDREN'S SPORT SCHOOL NRW (COLOGNE, GERMANY)

**Introduction** The effects of acute exercise on cortical brain activity and brain function have been reported in several studies. However, most of them examined adults and in some cases school children or the elderly. To the best of our knowledge there have been no studies which investigate such effects in pre-school children although this age-group is characterized by a particularly high plasticity of the central nervous system. **Methods** 8 male, pre-school children participated in the study (5.6±0.5 yrs; 122.4±4.2 cm; 22.1±2.7 kg). In a balanced cross over design participants either completed an exercise session (EXE) of 45 min duration or a control condition (CON) where they were allowed to paint and/or to talk to their parents. The exercise session consisted in 3 out of 5 different movement games (10 min each) that were introduced in a counterbalanced order and a soccer match (15 min) at the end of the session. Heart rate (HR) was recorded continuously before, during and after exercise as a measure of physical demand. The experiment started at 3 pm with two (eyes closed and eyes open) 1 min resting electroencephalographic (EEG) recordings. EEG data was Fourier transformed to provide estimates for absolute power in 8 frequency bands (delta to gamma), and analysed in 4 regions across the scalp. After the EEG, participant's reactive stress tolerance, attention and reaction speed (RT) in situations requiring continuous, swift and varying responses to rapidly changing visual and acoustic stimuli was assessed for 5 min using the children's version of the well-established determination test (DTKI, VIENNA TEST SYSTEM). EEG and DTKI were repeated approximately 20 min after the intervention, when heart rate returned to baseline values (POST). Both, median RT and EEG band power were expressed as a percentage of the PRE value, thus reducing interindividual and day-to-day variations. **Results** Average HR during the exercise session was 150.2±15.8 1/min. The median RT in the DTKI was significantly lower in EXE compared to CON (p<0.001). Lower-1 alpha power was reduced for CON compared to EXE (p<0.05) in the eyes open condition. Furthermore, beta1 and beta2 power were significantly lower in the frontal cortex for EXE compared to CON (p<0.001). **Discussion** The results of the present study suggest that acute exercise can improve children's cognitive performance. This effect could be mediated by exercise-induced neural efficiency which is reflected by decreased desynchronisation in the widespread lower-1 alpha band when the eyes are open and reduced beta1 and beta2 power in the frontal cortex after exercise.

#### EFFECTS OF TRANSCRANIAL DIRECT CURRENT STIMULATION ON MAXIMAL VOLUNTARY ISOMETRIC STRENGTH AND MUSCLE ENDURANCE OF THE ELBOW FLEXORS

KAN, B., DUNDAS, J.E., NOSAKA, K.

EDITH COWAN UNIVERSITY

**EFFECTS OF TRANSCRANIAL DIRECT CURRENT STIMULATION ON MAXIMAL VOLUNTARY ISOMETRIC STRENGTH AND MUSCLE ENDURANCE OF THE ELBOW FLEXORS** Kan, B.1, Dundas, J.E.2, Nosaka, K.1 1 Edith Cowan University (AUSTRALIA), 2 University of Western Australia (AUSTRALIA) **Introduction** Transcranial direct current stimulation (tDCS) is a way of altering cortical excitability using low intensity (1-2 mA) direct current delivered to the scalp overlying a target region of the brain via electrodes connected to a controlled current unit. Cogiamanian et

al. (1) reported that a 10-min tDCS treatment (2 mA) attenuated the decrease in the time to failure (TTF) of an isometric muscle endurance task at 35% of maximal voluntary isometric contraction (MVC) strength of the elbow flexors from pre to post treatment test separated by 60 min. It should be noted that the TTF decreased in the post-treatment tests by 25% (tDCS) or 40% (control) in their study; however, our pilot study showed no decrease in TTF with a 60-min rest. The present study investigated the effects of tDCS on MVC strength and TTF of the elbow flexors, when the TTF was expected to be similar between the pre and post treatment tests in control condition. Methods Fifteen healthy men (18-50 y) participated in the study after providing the informed consent. MVC strength and TTF at 30% MVC were measured before and immediately after a 10-min tDCS or sham treatment set at 50 min after the baseline measures on three separate occasions. On two occasions, direct current (2 mA) was delivered through a pair of electrodes soaked in saline solution placed on the scalp of the right hemisphere motor cortex controlling the left arm (anode) while the cathode placed over the right shoulder. One occasion was a sham treatment where no current was delivered. The order of the conditions was blinded to the subjects and randomised. Changes in MVC strength and TTF from pre to post treatment were compared between tDCS and sham treatments by a two-way repeated measures ANOVA. Results The two tDCS conditions showed similar responses. No significant difference in the baseline MVC strength was evident between the tDCS and sham treatments. MVC strength decreased by ~5.9 % ( $P < 0.05$ ) from pre to post measurements, but no significant difference in the changes was evident between treatments. TTF did not change significantly from pre to post, and no significant difference was found between treatments. Discussion The present study did not find significant effect of tDCS treatment on MVC strength and TTF, thus the previous study finding (1) was not replicated. The discrepancy between the present and previous study's results may be due to a difference in the TTF task (force task vs. position task). It seems that the effect of the tDCS treatment on cortical excitability in the present study was not strong enough to affect MVC strength and TTF. References 1) Cogiamanian F et al. ## EXERCISE, COGNITION AND INTELLECTUAL DISABILITY – A NEUROPHYSIOLOGICAL APPROACH

VOGT, T., ANNEKEN, V., BRÜMMER, V., STRÜDER, H.K., SCHNEIDER, S.

GERMAN SPORT UNIVERSITY

Introduction The relevance of exercise on health promotion is well accepted and has been addressed in several neuropsychological investigations (2, 4). These studies were mainly set up for healthy individuals. However, the benefits of exercise, such as general well being, physical and cognitive health enhancements (2) are becoming more important for everybody, thus for intellectually disabled individuals, too (3). Yet, there is no study investigating the neuropsychological correlates of exercise on intellectually disabled individuals. Therefore this study aimed to investigate the effects of exercise on neurophysiological correlates, underlined by cognitive processing in intellectually disabled individuals. Method Following a 30 min run (mean HR 154.50  $\pm$  14.43 bpm), 12 intellectually disabled participants (5) underwent a visual recognition and reaction time task using the evaluated Vienna Test System (control conditions without exercise). Before and after exercise a 3 min resting EEG was recorded on 32 positions according to the international 10-20 system (4). Data was analysed using standardized low-resolution electromagnetic tomography (sLORETA). Results sLORETA analysis revealed a significant decrease ( $p < 0.05$ ) in beta activity in the frontal lobe. Even though visual recognition as well as reaction time revealed no significant changes compared to control conditions, a decrease of activity in frontal lobe regions was found to be positively correlated with the cognitive tasks ( $p < 0.05$ ). Discussion With respect to a transient hypofrontality hypothesis (1) a decrease of (prefrontal) lobe activity can be regarded as the rearrangement of cortical activity, which coincides with cognitive states (1), such as decision-related processes. As to the literature our findings give reason to believe that exercise affects frontal lobe activity, related to cognitive processing in intellectually disabled individuals. ## CORTICAL REPRESENTATION OF SELF-PACED TREADMILL WALKING

KNAEPEN, K.1, FONTENELLE, V.1, FRENANDEZ, H.1, NAGELS, G.2, MEEUSEN, R.1

1: VRIJE UNIVERSITEIT BRUSSEL (BRUSSEL, BELGIUM); 2: MS-CENTRUM (MELSBROEK, BELGIUM)

Introduction Walking is a complex process that involves an accurate interaction between supraspinal centers, central pattern generators and multi-sensory peripheral sources. For gait rehabilitation purposes and the successful implication of brain-computer-interfaces, it is of great importance to know and understand the course of movement-related cortical potentials (MRCPs) during complex movements such as human gait. In this study the use of active electroencephalography (EEG) electrodes combined with source localization techniques (sLORETA) respond to the challenges often seen during EEG registration (e.g., movement artifacts) and allow for the assessment of MRCPs and active brain regions related to self-paced treadmill walking in healthy subjects. Methods Three men and 7 women (mean age 28.2  $\pm$  4.1 years) participated in this study. Thirty-two channel EEG data were recorded during 20 minutes of treadmill walking. Heelstrike (HS) of the left leg was detected by a foot contact sensor. EEG data were segmented into epochs of 1000 msec around HS and averaged to one MRCP for each subject. Individual waveforms were averaged to a single grand average MRCP for each channel. The averaged MRCPs for each subject were imported and statistically analyzed into sLORETA in order to compute cortical sources of activity. Results EEG traces over the motor cortex show a slow decrease in brain potential, which starts around -240 msec in relation to HS. From this point until -140 msec prior to HS a readiness potential window can be defined, followed by a fast increase in EEG negativity (the negative slope). A plateau tendency appeared between -60 and -20 msec, indicating the motor potential window. The maximum EEG activity is reached within the first 20 msec following HS. This negative potential is rapidly followed by a positive potential, creating the movement-monitoring potential following HS. sLORETA shows the greatest negativities of the MRCPs over the left sensorimotor cortex. Discussion This is the first study that uses EEG to define MRCPs and active brain regions during self-paced treadmill walking. EEG registration during gait exposes gait-related cortical potentials in the motor cortex around the moment of HS. The greatest negative potentials during walking can be found in the left hemisphere. This points out that bilateral coordination preferentially recruits the left hemisphere and the left hemisphere probably regulates limb position and posture during human walking (Serrien et al., 2006). Moreover, as in the study of Gwin et al. (2010), we found that cortical activity in the left sensorimotor cortex is more pronounced for ipsilateral heel-strike. References Gwin JT, et al. (2011). *NeuroImage*, 54(2), 1289-96. Serrien DJ, et al. (2006). *Nat Rev NeuroSci*, 7, 160-67.

**EFFECTS OF END-TIDAL PCO<sub>2</sub> CLAMPING ON BRAIN BLOOD FLOW AND MAXIMAL EXERCISE CAPACITY IN HYPOXIA**

FAN, J., STUCKY, F., KAYSER, B.

UNIVERSITY OF GENEVA

**Introduction** During heavy exercise, hyperventilation-induced hypocapnia leads to cerebral vasoconstriction, resulting in a reduction in cerebral blood flow (CBF). In hypoxia, a reduction in CBF would impair cerebral O<sub>2</sub> delivery and potentially account for the reduced exercise performance in hypoxia. We tested the hypothesis that PETCO<sub>2</sub> clamping in hypoxia exercise would prevent the hypocapnia-induced reduction in CBF during heavy exercise and improve exercise capacity. **Methods** We measured end-tidal PCO<sub>2</sub> (PETCO<sub>2</sub>) and PO<sub>2</sub> (PETO<sub>2</sub>), ventilation (VE), middle cerebral artery velocity (MCAv; index of CBF), peripheral O<sub>2</sub> saturation (SpO<sub>2</sub>) and cerebral O<sub>2</sub> supply index (MCAv times SpO<sub>2</sub>) in ten healthy men (age 24±3 yrs; VO<sub>2</sub>max 57.4±10.9 ml/min/kg; mean±SD) during incremental cycling to exhaustion (0.5 W/s) in normoxia and hypoxia (FIO<sub>2</sub> = 0.10) with and without PETCO<sub>2</sub>-2 clamping. PETCO<sub>2</sub> clamping was achieved by increasing FICO<sub>2</sub> whilst keeping FIO<sub>2</sub> constant. In normoxia we increased PETCO<sub>2</sub> to 43±2 mmHg. In hypoxia we aimed PETCO<sub>2</sub> values similar to those observed in normoxia (40±2 mmHg). **Results** During normoxia, PETCO<sub>2</sub> clamping elevated resting PETCO<sub>2</sub>, PETO<sub>2</sub>, VE, MCAv and cerebral O<sub>2</sub> supply index by 7±2 mmHg, 20±4 mmHg, 12.7±4.5 L/min, 33±10% and 26±17% respectively (P<0.001), while SpO<sub>2</sub> was unchanged (P>0.05). PETCO<sub>2</sub> clamping in hypoxia elevated resting PETCO<sub>2</sub>, PETO<sub>2</sub>, VE, MCAv, SpO<sub>2</sub> and cerebral O<sub>2</sub> supply index by 8±3 mmHg, 10±4 mmHg, 12.0±6.6 L/min, 34±16%, 6±4% and 33±27% respectively (P<0.001; P<0.001; P<0.001; P<0.05; P<0.01; P<0.01). During normoxic exercise, PETCO<sub>2</sub> clamping elevated PETCO<sub>2</sub> by 7±3, 6±3, 6±3, 10±4, 17±4 mmHg at 20, 40, 60, 80 and 100%Wattmax respectively (P<0.001), while MCAv was elevated by 19±19, 21±18, 26±20, 33±21, and 49±20% at these exercise intensities (P<0.05). During hypoxic exercise, PETCO<sub>2</sub> clamping elevated PETCO<sub>2</sub> by 12±3, 12±2, 14±2, 16±3 and 20±3 mmHg at 20, 40, 60, 80 and 100%Wattmax respectively (P<0.001), while MCAv was elevated at 100%Wattmax only (by 19±12%; P<0.05). PETCO<sub>2</sub> clamping did not alter maximal exercise capacity in either normoxia or hypoxia (P>0.05). At peak exercise, the cerebral O<sub>2</sub> supply index was similar in normoxia and hypoxia in the unclamped condition (P>0.05). PETCO<sub>2</sub> clamping elevated the cerebral O<sub>2</sub> supply index at peak exercise by 46±25% during normoxia (P<0.001), but no change was observed during hypoxia (P>0.05). No differences were observed in power output, PETO<sub>2</sub>, VE and SpO<sub>2</sub> with PETCO<sub>2</sub> clamping at peak exercise during either normoxic or hypoxia conditions (P>0.05). **Discussion** In hypoxia PETCO<sub>2</sub> clamping did not change cerebral O<sub>2</sub> supply index at peak exercise despite elevated CBF. Despite normalization of PETCO<sub>2</sub> to normoxic values we did not observe an improvement in exercise capacity, thus refuting our hypothesis.

**Oral presentations****OP-PM05 Exercise: Signalling****COSTAMERIC FOCAL ADHESION KINASE ORGANISES LOAD-DEPENDENT P70S6K SIGNALLING IN SKELETAL MUSCLE**

FLUECK, M., LI, R., RUOSS, S., SEYNES, O., ERSKINE, R.M., NARICI, M.

MANCHESTER METROPOLITAN UNIVERSITY

**Introduction:** Skeletal muscle mass shows pronounced load dependence but the organization of the signalling processes relaying mechanical loading with anatomical changes in muscle is not known. We hypothesized that sarcolemmal adhesion sites of muscle fibres (costameres) are implicated in the load-dependent regulation of p70S6K signalling towards protein synthesis. **Methods:** Focal adhesion kinase (FAK) was overexpressed alone or in combination with its inhibitor, FRNK, in rat soleus muscle (Durieux 2009). Loading of rat soleus muscle was modified with hindlimb suspension and reloading or bilateral tenotomy of the achilles tendon. Loading to human vastus lateralis muscle was modified by bedrest and resistance exercise. Gamma- and meta- vinculin and FAK and p70S6K kinase were assessed by immunoblotting in total homogenates of muscle samples. Pre post changes were compared with a paired T-test. **Results:** Overexpression of focal adhesion kinase (FAK) in rat soleus muscle upregulated the content of the costamere components, gamma- and meta- vinculin (+153%), p70S6K protein (+40%), and ribosomal transcripts. The expression of p70S6K (-83%), gamma- (-39%) and meta- vinculin (-49%) was reduced with hindlimb unloading and raised again within 24 h of reloading (p70S6K: 10x; vinculin: 1.5x) in corresponded to activated FAK (Y397 phosphorylation). Similarly, 24 h of soleus muscle overload increased the content and activation status of FAK and p70S6K. 1 h after overload the phosphorylation of p70S6K, AKT and 4E-BP1 was elevated. At this point the content of activated FAK was reduced but was re-established with co-overexpression of FAK and FRNK, in co-relation with p70S6K content (r=0.74). Changes in muscle loading to human vastus lateralis muscle by bedrest and resistance training reproduced the relationships between FAK, FAK-pY397 and meta-vinculin. **Discussion:** The observations indicate that remodelling of costameres via FAK is coupled to the load-dependent control of protein synthetic capacity in vertebrate muscle. This supports the concept that signalling pathways themselves demonstrate use-dependent plasticity. **References:** Durieux AC, D'Antona G, Desplanches D, Freyssenet D, Klossner S, Bottinelli R, Flück M. **FUNCTIONAL ANALYSIS OF THE 3'-UTR OF THE COL5A1 GENE: IMPLICATIONS FOR 'EXERCISE-RELATED PHENOTYPES'**

COLLINS, M.1,2,3, LAGUETTE, M.J.1, ABRAHAMS, Y.1, POSTHUMUS, M.1,3, PRINCE, S.1

1: DEPARTMENT OF HUMAN BIOLOGY, UNIVERSITY OF CAPE TOWN (UCT), CAPE TOWN, SOUTH AFRICA, 2: MEDICAL RESEARCH COUNCIL, CAPE TOWN, SOUTH AFRICA, 3: IOC RESEARCH CENTRE, UCT, CAPE TOWN, SOUTH AFRICA.

**Introduction** COL5A1 encodes the α1 chain of type V collagen, a minor fibrillar collagen that regulates fibrillogenesis within non-cartilaginous connective tissues. We have shown that a common C to T single nucleotide polymorphism (rs12722) within the COL5A1 3'-untranslated region (UTR) is associated with a number of sports injuries (such as Achilles tendinopathy; AT) and performance related phenotypes. To provide functional evidence for these genetic associations, the aim of this study was to determine the biological function of the COL5A1 3'-UTR. **Methods** The entire COL5A1 3'-UTR from four AT patients and three controls were cloned, from genomic DNA using nested PCR, within the pGL3-Promoter vector, substituting the poly (A) signal of the firefly-luciferase reporter gene. The constructs were transiently co-transfected with an internal control HT1080 cells. The normalised results were expressed as relative luciferase activity. Based on the functional data we propose that musculoendoneous unit stiffness is the underlying mechanism that explains our reported genetic associations. **Results** There was statistically significantly higher activity in the luciferase activity of the AT clones (87.5±14.3%) when compared to the control clones (67.6±20.0%, p=0.007). Two major forms of the COL5A1 3'-UTR were identified when all the cloned 3'-UTRs were sequenced. One form (WT-allele) was predominantly identified in the controls, while the second form (TEN-allele) was pre-

dominately identified in AT subjects. The luciferase activity of the WT-allele was also significantly lower than the TEN-allele ( $68.3 \pm 24.9\%$  vs  $86.0 \pm 18.5\%$ ,  $p < 0.001$ ). Conclusion Two major COL5A1 3'-UTR alleles were identified; one from the AT patients and the other from the asymptomatic controls. There was an overall increase in mRNA stability for the TEN-allele. These results demonstrate that the COL5A1 3'-UTR may play an important regulatory role which could result in susceptibility to musculoskeletal soft tissue injuries and other phenotypes. We therefore hypothesize that this results in an increased type V collagen content, which will alter fibril assembly, decrease fibril diameter and thus biomechanical properties. These changes may result in the observed associations with injury and performance phenotypes. Evidence for this hypothesis is supported by clinical features, such as joint hypermobility, and the biochemical architecture of connective tissue within patients with classic Ehlers-Danlos syndrome (EDS) and a col5a1 knock-out mouse model.

### THE COL3A1, COL5A1 AND COL6A1 GENES AND EXERCISE ASSOCIATED MUSCLE CRAMPS AMONG IRONMAN TRIATHLETES

O'CONNELL, K.1, POSTHUMUS, M.1,3, SCHWELLNUS, M.1,3, COLLINS, M.2,1,3

1: MRC/UCT RESEARCH UNIT FOR ESSM, UCT, SOUTH AFRICA 2: SOUTH AFRICAN MRC, TYGERBERG, SOUTH AFRICA 3: IOC RESEARCH CENTRE, NEWLANDS, SOUTH AFRICA

Introduction EAMC is a common condition seen in participants of endurance events such as ultra-marathons and triathlons. Despite its high prevalence, little is known about the aetiology of EAMC (Schwellnus, 2009). The altered neuromuscular control hypothesis suggests that genetic predisposition may play a role in the aetiology of EAMC (Schwellnus, 2009). We propose variants within the COL3A1, COL5A1 and COL6A1 genes may modulate risk of developing EAMC, since these genes are known to exert effects on soft-tissue, including tendons, ligaments and muscles. Methods Two hundred and ninety eight participants with self-reported history of EAMC within the last 12 months prior to the event were included as cases in this study (hEAMC group). One hundred and fifty nine participants with no self-reported history of EAMC were included as controls (CON group). All participants were genotyped for the COL5A1 BstUI restriction fragment length polymorphism (RFLP), the COL3A1 E30+2209 G/A and COL6A1 IVS32-29 T/C polymorphisms. Results When participants  $\geq 35$  yrs were analysed, the COL5A1 BstUI CC genotype was significantly associated with development of EAMC ( $p = 0.006$ ). Specifically the COL5A1 BstUI CC genotype was significantly under-represented (OR = 2.9, 95% CI 1.4–5.9;  $p = 0.003$ ) in the hEAMC group (CC genotype 11.0%) when compared to CON group (CC genotype 26.4%). No significant genotype differences were found for the COL3A1 E30+2209 G/A ( $p = 0.731$ ) and COL6A1 IVS32-29 T/C ( $p = 0.986$ ) polymorphisms between the hEAMC and CON groups. Conclusion This study identified, for the first time, the COL5A1 gene as a potential marker for the development of EAMC. These effects may be mediated through the effects that type V collagen exerts on the mechanical properties of musculoskeletal soft tissues. References Schwellnus M. (2009). Br J Sports Med, 43, 401-408.

### SIGNALLING RESPONSES OF HUMAN SKELETAL MUSCLE TO HIGH-INTENSITY INTERVAL RUNNING VERSUS MODERATE-INTENSITY CONTINUOUS RUNNING

BARTLETT, J.D.1, JEONG, T.S.1, GREGSON, W.1, DRUST, B.1, CLOSE, G.L.1, COCHRAN, A.2, GIBALA, M.J.2, MORTON, J.P.1

1: LJMU (LIVERPOOL, UK), 2: MCMASTER UNIVERSITY (ONTARIO, CANADA)

Introduction We recently demonstrated that high-intensity interval (HIT) running is perceived as more enjoyable than moderate-intensity continuous (CONT) running (Bartlett et al. 2011). Such data have implications for improving exercise adherence and long-term health, especially considering that HIT cycling is a more time-efficient training stimulus than CONT cycling for improving skeletal muscle oxidative capacity (Gibala et al. 2006). Despite running being the most readily available form of exercise to the general population, comparable data for this exercise mode are lacking. The aim of this study was to therefore test the hypothesis that acute HIT running is a more potent exercise stimulus than CONT running for activating key signal transduction pathways associated with mitochondrial biogenesis. Method Muscle biopsies (vastus lateralis) were obtained from six active men who performed two running protocols consisting of HIT or CONT in a randomized manner separated by 7-days. HIT consisted of 6 x 3 min at 90 %  $\text{VO}_{2\text{max}}$  interspersed with 3 min recovery periods at 50 %  $\text{VO}_{2\text{max}}$ , plus a 7 min warm-up and cool down at 70 %  $\text{VO}_{2\text{max}}$ . CONT consisted of 50 min of continuous running exercise at 70 %  $\text{VO}_{2\text{max}}$ . The protocols were matched for energy expenditure, average intensity, average heart rate, duration and distance ran (Bartlett et al. 2011). Results Phosphorylation (P-) of p38MAPKThr180/Tyr182 increased after both trials ( $P < 0.05$ ), but the increase in HIT ( $2.2 \pm 0.1$ -fold) was greater than CONT ( $1.5 \pm 0.2$ -fold) ( $p < 0.05$ ). Similarly, P-AMPKThr172 increased immediately after exercise ( $P < 0.05$ ), with a tendency for the change to be greater in HIT vs CONT ( $1.8 \pm 0.3$  vs  $1.4 \pm 0.1$ -fold;  $P = 0.07$ ). Exercise did not change the total protein content of PGC-1 $\alpha$  or GAPDH in either condition ( $p > 0.05$ ). Discussion These preliminary data suggest that HIT running may be a more potent stimulus than CONT running for activating key signaling kinases involved in stimulating mitochondrial biogenesis. Despite both protocols being matched for work done, our data suggest that it is the variations in exercise intensity as opposed to energy expenditure per se which ultimately determines the metabolic responses of skeletal muscle. The precise mechanisms underpinning the enhanced p38MAPK phosphorylation remain unknown and biopsy samples are currently being analysed for markers of metabolic and oxidative stress and downstream markers linked to mitochondrial biogenesis. ### INCREASED FOCAL ADHESION KINASE IN ELDERLY HUMAN SKELETAL MUSCLE AFTER 12 WEEKS RESISTANCE TRAINING

WILSON, O.1, VERDIJ, L.B.2, VAN LOON, L.J.C.2, SHAW, C.S.1, WAGENMAKERS, A.J.M.1

1: UNIVERSITY OF BIRMINGHAM, UK; 2: MAASTRICHT UNIVERSITY, NL

Introduction Focal adhesion kinase (FAK) is one of the component enzymes of sarcolemmal focal adhesion complexes, which convert mechanical stimuli into intracellular signalling. Increased FAK protein content and phosphorylation with loading is associated with hypertrophy in animal skeletal muscle, while unloading is associated with atrophy and a reduction in FAK. In humans a reduction in habitual physical activity contributes to the loss of skeletal muscle mass and strength with age. Therefore, we used immunofluorescence microscopy to test the hypothesis that a 12 week progressive resistance training program would increase FAK content and phosphorylation in skeletal muscle fibres of previously untrained elderly men. Methods Nine healthy, insulin sensitive elderly males ( $73 \pm 6$  y;  $26.8 \pm 3.7$  kg/m $^2$ ) completed a 12 week resistance training program with percutaneous vastus lateralis muscle biopsies collected pre- and post-training. Cryosections were incubated with FAK antibodies for visualisation in muscle fibres and plasma membrane. Anti-myosin heavy chain type

I was used for fibre type differentiation. Muscle sections were also incubated with wheat germ agglutinin-350 for identification of the plasma membrane. Fibre type differences in the intensity of FAK immunofluorescence were determined using image analysis software. Results At baseline, mean type I muscle fibre area was significantly higher than type II fibres ( $P=0.009$ ) but type II fibre area increased after training ( $P=0.016$ ). In both fibre types, a greater FAK immunoreactivity was detected at the (sub)sarcolemmal regions compared with deeper areas of the myofibre, particularly in type I fibres. However, there was no difference in myofibre FAK content pre-training between type I and type II fibres. Following training, a strong (sub)sarcolemmal FAK immunoreactivity was detected in both fibre types, especially in type II fibres. There was no change in type I fibre FAK content ( $P=0.07$ ) but there was a 29% increase in type II fibres ( $P=0.016$ ) respectively. This resulted in significantly more FAK in type II than type I fibres ( $P=0.013$ ). There was also an 18% increase in the plasma membrane FAK content post-training ( $P=0.024$ ). Conclusion We show for the first time that previously untrained elderly individuals completing a resistance training program can increase FAK in type II muscle fibres and the plasma membrane. These data suggest FAK may play an important role in the adaptation to resistance training in elderly individuals.

#### PHYSICAL ACTIVITY AND LEISURE TIME HABITS IN SCHOLARS AGED 9-16: DIFFERENCES BY GENDER

VIUDA-SERRANO, A., RUIZ-VICENTE, D., THEIRS RODRÍGUEZ, C.I., PÉREZ, B., PARDO, R., SALINERO, J.J., GARCÍA-APARICIO, A.  
UNIVERSIDAD CAMILO JOSÉ CELA

PHYSICAL ACTIVITY AND LEISURE TIME HABITS IN SCHOLARS AGED 9-16: DIFFERENCES BY GENDER Viuda-Serrano, A.; Ruiz-Vicente, D.; Theirs Rodríguez, C.I.; Pérez, B.; Pardo, R.; Salinero, J.J.; García-Aparicio, A. Universidad Camilo José Cela INTRODUCTION Evidence strongly demonstrates that physical fitness and health status of children and youth are substantially enhanced by frequent physical activity (1), however recent studies in our country are discouraging. In the enKid study it was observed that 19.8% of boys and 30% of girls aged 10-13 never do sport activities (2). National Health Survey showed that less than 30% of the children between the ages of 6 and 15 are active (3). OBJECTIVE To analyze differences in physical activity and leisure habits between boys and girls aged 9-14 from schools that actively promote sports. METHOD 870 subjects (boys=443, girls=427), aged 9-16 (boys=12.2±1.8; girls=12.1±1.7) answered a modified version of the Assessment of Physical Activity Level Questionnaire (4). Descriptive statistics, contingency tables and contrast of means were used to analyze differences between boys and girls. RESULTS Significant gender differences were observed in the Physical Activity Index ( $t=7.765$ ;  $p=.000$ ) as well as in regulated sport activities participation ( $U=70,628$ ;  $p=.000$ ), recreational activities ( $U=77,659$ ;  $p=.042$ ), moderate and vigorous physical activity (MVPA) ( $U=67,920$ ;  $p=.000$ ) and participation in competitive sport ( $U=71,005$ ;  $p=.000$ ). 52.3% of boys did MVPA more than 2 hours a week, while only 29% of girls did so. 23.6% of boys and 37.1% of girls never played any organized sport. It was observed a significant relationship between gender and items such as "reading" ( $\chi^2=19.21$ ;  $p=.000$ ), "housework participation" ( $\chi^2=8.75$ ;  $p=.003$ ) or "family time" ( $\chi^2=7.75$ ;  $p=.021$ ) that were practiced by girls to a greater extent; whereas "playing with computer or video games" ( $\chi^2=15.59$ ;  $p=.000$ ), "going to sport events as spectator" ( $\chi^2=19.26$ ;  $p=.000$ ) or "playing sports" ( $\chi^2=44.51$ ;  $p=.000$ ) were wider practiced by boys. CONCLUSIONS They have been showed differences between boys and girls in the practice of physical and sport activities, as well as in other leisure-time activities. A reduced percentage of subjects reported a lack of sport practice, which confirms the importance given to sport in these schools. REFERENCES 1. Physical Activity Guidelines Advisory Committee. #### INFLUENCE OF PHYSICAL ACTIVITY INTENSITY AND PHYSICAL SELF-PERCEPTIONS ON WEIGHT STATUS AMONG 10-11 YEAR CHILDREN: THE CHANGE! PROJECT

FAIRCLOUGH, S.1,2, MACKINTOSH, K.1,2, GOBB, R.1,2, WARBURTON, G.1,2, RIDGERS, N.1,4, BODDY, L.1,2, DAVIES, I.1,2, HACKETT, A.1,2, STRATTON, G.1,3

1REACH GROUP, 2FACULTY FOR EDUCATION, COMMUNITY AND LEISURE, AND 3RESEARCH INSTITUTE FOR SPORT AND EXERCISE SCIENCES, LIVERPOOL JOHN MOORES UNIVERSITY, UK; 4CENTRE FOR PHYSICAL ACTIVITY AND NUTRITION

Background: Child overweight is an established risk factor for cardiometabolic disorders. Increased prevalence of overweight and obesity in developed countries has prompted interest in the influence of physical activity as a preventative intervention (Gutin, 2011). Children's physical self-perceptions are often associated with physical activity (Fairclough & Ridgers, 2010) but the influence on weight status of these related constructs is under-researched. The study purpose was to examine associations between children's physical activity intensity, physical self-perceptions, and weight status. Methods: Data were obtained from 274 children (154 girls) aged 10-11 years. Standard anthropometric measurements were used to establish BMI and maturity offset values. Children were categorised as normal-weight (NW), or overweight/obese (OW) using the IOTF BMI cutpoints. Habitual physical activity was assessed using accelerometry, and children completed the Children and Youth version of the Physical Self-Perception Profile. Sex-specific logistic regression adjusted for age and maturation assessed associations between different physical activity intensities, physical self-perceptions, and weight status. Results: For boys moderate physical activity (MPA) was positively associated with OW (OR = 1.01 [1.01, 1.19],  $p = 0.024$ ), while an inverse association was observed for vigorous physical activity (VPA; OR = 1.33 [1.06, 1.67],  $p = 0.011$ ). Among girls OW was positively associated with perceived strength (OR = 4.97 [1.46, 16.94],  $p = 0.01$ ), and inversely associated with perceived attractiveness (OR = 4.55 [1.67, 12.5],  $p = 0.003$ ). Physical self-perceptions did not predict weight status in boys, while in girls being OW was not associated with sedentary time or physical activity. Conclusions: Boys' engagement in VPA may be a stronger predictor of being OW than MPA, as VPA has previously been shown to associate with body composition (Gutin, 2011) and cardiorespiratory fitness (Parikh & Stratton, in press). Physical self-perceptions had a stronger predictive influence on girls' weight status among girls physical activity. Physical activity and physical self-perceptions influence boys' and girls' weight status differently. References Fairclough, S. J., & Ridgers, N. D. (2010). *J Sports Sci*, 28, 1-9. Gutin, B. ## ASSESSMENT OF PHYSICAL ACTIVITY BY QUESTIONNAIRES AND ACCELEROMETERS

WAGNER, P.1, JAITNER, T.2, BEIER, K.1, ECKERT, K.1

1: UNIVERSITY OF LEIPZIG, 2: UNIVERSITY OF KAISERSLAUTERN

**Introduction** The determination of the degree of physical activity in the population and various sub-groups is essential for answering questions on health sciences, e.g. for the identification of target groups for health-related interventions. In general, the level of activity in the population is diagnosed on survey inventories. What quality is determined in this way data is largely unknown (Wagner & Singer, 2003). Aim of the present study was to compare subjective self-report data with objective accelerometer. **Methods** The physical activity level of 45 adults, 23 Men and 22 Females (23-59 years, M= 33,3 years, SD=10,6 years) were recorded for over a week via physical-activity diary, accelerometer (Personal Activity Monitor, PAM) on the modified physical activity questionnaire (Baecke et al., 1982, Wagner & Singer, 2003). The data from the accelerometer as well as the with the diary data calculated metabolic equivalent were averaged for the inquiry period and compared with activity indices (Complete, Working, Exercise, Leisure-Time). **Results** Significant positive correlations have been found between the data from the PAM and the MET's ( $r=.38$ ,  $p<.05$ ) as well as between the PAM data and the Baecke-Index ( $r=.43$ ,  $p<.01$ ). Slightly positive correlations with the Leisure-Time-Index and the Working-Index have not been significant. The Working-Index correlates positive with the MET-data ( $r=.42$ ,  $p<.01$ ). Furthermore there have been significant differences of the PAM data regarding the regularity of exercising ( $p<.05$ ,  $F=3,24$ ). **Discussion** The correlation between the self-reported data and the PAM data are similar to existing validation studies (Cust et al., 2008). An additional validation and review/revisal is recommended for decisions and interventions based on self-reported physical activity data. **References** Baecke JA, Burema J, Frijters JE (1982) Am J Clin Nutr, 36, 936-942. ## WITHIN DAY VARIABILITY OF OBJECTIVELY MEASURED PHYSICAL ACTIVITY DURING WEEKDAYS AND WEEKEND DAYS IN PRESCHOOL CHILDREN

O'DWYER, M.V.1, KNOWLES, Z.1, FAIRCLOUGH, S.J.1, RIDGERS, N.D.2, FOWEATHER, L.1, STRATTON, G.1

1 THE REACH GROUP, LIVERPOOL JOHN MOORES UNIVERSITY, UK 2 CENTRE FOR PHYSICAL ACTIVITY AND NUTRITION RESEARCH, DEAKIN UNIVERSITY, AUSTRALIA

**Introduction** There is inconclusive evidence for a causal link between physical activity (PA) and health outcomes in preschool children. Despite the common perception from practitioners that preschool children are receiving sufficient PA, data suggest they do not meet the PA recommendations (O'Dwyer et al. 2011). It is important to increase PA however evidence concerning the timing of successful preschool interventions remains inconclusive. The aim of this study was to explore within day variability of PA during weekdays and weekend days. **Methods** Participants ( $n=240$ ; 52% male, Mage =  $4.4\pm0.6$  years) were randomly selected from 12 schools in North West England. PA was measured using the GT1M Actigraph uniaxial accelerometer for 7 consecutive days every 5 seconds, and analysed using age-specific cut points. For inclusion in the analyses, participants were required to have worn the monitors on 3 days (including one weekend day). School attending days and weekend days were segmented into before school (07:00-09:00), during school (09:00-15:00) and after school (16:00-19:00) and morning (08:00-11:00), daytime (12:00-16:00) and evening (17:00-20:00), respectively. A two way between groups analysis of variance was conducted to explore the impact of gender and age moderate-to-vigorous physical activity (MVPA) across different segments of weekdays and weekend days. **Results** Preschoolers spent 6.9% (average: 42.3 minutes) of the day in MVPA while 81.5% (average: 642.5 minutes) was time spent sedentary. During preschool attending days (09:00h-15:00h), boys accumulated more MVPA than girls ( $p=.014$ ). During the weekend day (12:00h-15:00h) boys engaged in more MVPA ( $p=.008$ ). There were no age and gender differences found for the other segments of the day. **Discussion** Boys were more active during specific segments of the school day and weekend day. It may be potentially beneficial to incorporate PA interventions into preschool attending hours specifically for girls. Patterns of physical activity in preschool children appear to be consistent across both weekdays and weekend days though evidence of within day variability was found. Periods of the day susceptible to the improvement of PA were also revealed. Patterns of PA during preschool attending hours demonstrated that schools and childcare settings can play an important role in the promotion of PA, yet the home environment should also be targeted given the low levels of PA in this population. **References** O'Dwyer M.V., et al. (2011) Physical activity in non-overweight and overweight children: Preliminary findings and methods of the Active Play Project. Science and Sports, doi:10.1016/j.scispo.2011.01.006

## PHYSICAL ACTIVITY LEVELS, PREFERENCES AND IMPAIRMENTS AMONG PORTUGUESE COLLEGE STUDENTS

VIEIRA, S.1, ESTEVES, D.1,2, BRÁS, R.1,2, PINHEIRO, P.

1UBI (COVILHÃ, PORTUGAL), 2CIDESD (PORTUGAL), 3NECE (COVILHÃ, PORTUGAL)

**Introduction** Many health behaviors are established during late adolescence and early adulthood, so the decline in physical activity in adolescence and young adulthood, when many attend college, is a disturbing trend (Buckworth & Nigg, 2004). Recent research suggests that a significant percentage of college students do not get adequate physical activity (PA) (Staten et al. 2005; Irwin, 2007). Therefore, the aim of this study is to identify PA levels of a cohort of college students, along with motivational factors that affect it. **Methods** The study included a randomly recruited sample of 200 subjects (31% males; 69% females), age  $20.4\pm3.31$  years old. PA was assessed by IPAQ. A survey was designed to (1) evaluate participation in physical activities; (2) identify main reasons not to participate in PA; (3) evaluate perceptions on importance of PA for health and (4) identify preferences over different physical activities. Descriptive statistics were used to analyze data. **Results** IPAQ found 22.5% of students LOW; 55.5% MODERATE and 22.0% HIGH, regarding PA. Most students don't participate in PA in university (82.0%) nor outside the campus (70.5%). Lack of time (63%), activities schedule (40%), price (24.0%) and distance (22.0%), were the main reasons found for low participation in PA. Disease prevention (82%); stress management (54.5%); have fun (44.5%) and improve body beauty (43.5%) are the main benefits perceived of PA. **Results** identify collective sports, with friends (64.4%); cycling (63.4%) and group outdoor activities (54.1%) as preferred activities. **Discussion** Almost a quarter of interviewed college students are physically inactive. Existing physical activities may not meet students' preferences; leading to low participation level. Similar results were reported by Behrens & Dinger, (2003). In order to design effective PA offer it is necessary to understand college students' patters of participation and causes for no participation, together with their preferences. **References** BEHRENS, TK & Dinger, MK (2003). ### OP-PM14 Training and Testing: Soccer

#### THE RELATIVE AGE EFFECT IN EUROPEAN PROFESSIONAL FOOTBALL: A 10 YEAR FOLLOW-UP STUDY

HELSEN, W.1, MICHIELS, S.1, WILLIAMS, M.2, VAN WINCKEL, J.1

1: K.U.LEUVEN (BELGIUM), 2: LIVERPOOL JOHN MOORES UNIVERSITY (UK)

**Introduction** The relative age effect (RAE) refers to an asymmetry in the distribution of birth dates favouring players born early in the selection year and discriminating participants born in the last months of the selection year (Helsen et al., 2005). In this study, a follow-up study compared the distribution of the birth dates of both the players and the coaches in ten European countries in the 2000-01 and 2010-11 competitive seasons. Methods Kolmogorov Smirnov tests assessed differences between observed and expected birth-date distributions. Chi square goodness-of-fit tests were used to compare differences between the observed and expected birth-date distributions across the quarters of the selection year. Regression analyses were used to determine if there was a negative correlation between the number of players and the month which they were born in. Results On average, the percentage of home country players decreased from 66.5% in the 2000-01 season to 56.6% in the 2010-11 season, while the percentage of foreigners increased from 33.5% to 43.4%, respectively. The results also indicated a relative age effect in both seasons ( $P < 0.01$ ) with an over-representation of players born in the first quarter (29.3% in 2000-01; 31.9% in 2010-11) and an under-representation of players born in the last quarter (19.8% in 2000-01; 18.4% in 2010-11). There was no RAE for the coaches. Discussion Previous studies indicated that children born early in the school year have a greater chance on success in education than children born late in the school year (Barnsley et al., 1992). The same was shown in sport, in particular in football (Musch & Grondin, 2001). In line with recent studies in German (Cobley et al., 2008) and in Spanish football (Jimenez and Pain, 2008), we conducted a follow-up study to compare the birth-date distributions of professional football players in ten European countries between the 2000-01 and 2010-11 competitive seasons. We hypothesized that the RAE would decrease during the last decade based on two arguments. First, various solutions to reduce the RAE were discussed in previous studies. Second, in the 2000-2001 competitive season, the players were exposed to the old cut-off date in their education. Before 1997, the selection period started in August, whereas since 1997, the selection period started in every country in January (Helsen et al., 2005). Players of the 2010-2011 competitive season were exposed to both cut off dates during their player development. Interestingly, the RAE did not decrease over the course of the past ten years, on the contrary. The underlying mechanisms will be discussed as well as potential solutions to reduce the impact of the relative age effect. References Barnsley, R.H., Thompson, A.H., & Legault, P. (1992). *Int. #### VALIDATION OF THE LOUGHBOROUGH SOCCER PASSING TEST FOR USE WITH YOUNG SOCCER PLAYERS

ZOUHAL, H., RUÉ, O., BEN ABDERRAHMAN, A., HAMMAMI, M.A., BEN OUNIS, O., LE MOAL, E., ALI, A.

MOVEMENT SPORTS AND HEALTH SCIENCES LABORATORY

**VALIDATION OF THE LOUGHBOROUGH SOCCER PASSING TEST FOR USE WITH YOUNG SOCCER PLAYERS** Zouhal H1; Rué O1; Ben Abderrahman A1,2; Hammami M.A1,2; Ben Ounis O2; Le Moal E1; Ali A3. 1 M2S Laboratory, University of Rennes 2-ENS Cachan. Rennes, France. 2 LPEF, Faculty of Medicine Ibn Eljazzar, Sousse, Tunisia. 3 IFNHH Massey University, Auckland, New Zealand. **Introduction** Ali et al. (2007; 2008) developed the Loughborough Soccer Passing Test (LSPT) to assess the multifaceted aspects of soccer skill including passing, dribbling, control and decision-making. This test has been validated for adult soccer players. However, data concerning young soccer players aged 14-17 are required to recommend this test for talent identification. Consequently, the aim of this study was to validate the LSPT for use with young soccer players. **Method** A total of 87 young soccer players, aged 14-17, participated in the study. Participants were grouped according to playing level: elite (n=44); sub-elite (n=22) and non-elite (n=21). The LSPT requires players to complete 16 passes against colored target areas, whilst maneuvering around a grid of cones, as fast and as accurately as possible. Participants completed 12 attempts to familiarize themselves with the test before undergoing two main trials separated by one week; the mean of the two attempts was recorded as the performance score. All trials were performed inside a sports hall and using an indoor soccer ball. **Results** The results of the global performance (time + penalty time (s)) show significant differences ( $p < 0.01$ ) between the three groups, elite ( $49.3 \pm 11.0$  s), sub-elite ( $58.1 \pm 10.8$  s) and non-elite players ( $66.5 \pm 10.3$  s). Significant relationships were observed between trials for all the players concerning time ( $r = 0.73$ ,  $p < 0.01$ ), penalty time ( $r = 0.67$ ,  $p < 0.01$ ) and global performance ( $r = 0.78$ ,  $p < 0.01$ ). No differences were found for the three test components between the two main trials and for each group, using t-test ( $p < 0.05$ ). The difference percentage between the two main trials was very weak for all the players (-1.9 % for time, -5.7% for penalty time and -2.9% for global performance). The mean ratio multiplied or divided by the agreement ratio indicated greater reliability for the time component as opposed to global performance for all players ( $0.98^* / 1.1$  vs.  $0.97^* / 1.4$ ) and for each group ( $0.98^* / 1.31$  vs.  $0.98^* / 1.24$  in elite players and sub-elite players;  $0.99^* / 1.4$  vs.  $1.00^* / 1.5$  in non-elite players). **Discussion and conclusion** We used the same statistic tests than the studies of Ali et al. (2007; 2008) to explore validity and reliability of the LSPT in young players. Our results confirm that the test is a valid and reliable protocol to assess differences in soccer skill performance and can distinguish players according to their playing level. So, such test could be integrated in a battery of soccer tests in order to evaluate skill aspects of young players. #### FACTORS INFLUENCING REFEREES' RATINGS OF PERCEIVED EXERTION DURING COMPETITIVE SOCCER MATCHES

WESTON, M., CASTAGNA, C., BATTERHAM, A.M.

TEESSIDE UNIVERSITY

**FACTORS INFLUENCING REFEREES' RATINGS OF PERCEIVED EXERTION DURING COMPETITIVE SOCCER MATCHES** Weston, M.1, Castagna, C.2, Batterham, A.M.1 Teesside University, UK, 2University of Roma, Italy **Introduction** Ratings of perceived exertion (RPE) are an accurate means of monitoring exercise intensity (Borg, 1982), and provide a gestalt measure representative of both internal and external load

(Coutts et al., 2007). However, external load in high-level sport is characterised by both technical and physical demand. The aim of this preliminary investigation was to examine the role of these demands on referees' RPE scores following competitive soccer matches. Methods Data were collected from 17 elite referees for 283 Premier and Football League matches over the duration of the 2008/09 English soccer season. The referees recorded their RPE (CR10 scale) 30-min after each match ended to obtain a global intensity rating for the entire match (Foster, 1998). A priori we defined four variables representing the technical and physical match demand: 1) disciplinary points (10 points per yellow card; 25 points per red card); 2) distance from the ball (m); 3) total referee high-speed running (speed >19.8 km•h<sup>-1</sup>); 4) total player high-speed running (speed >19.8 km•h<sup>-1</sup>). The running variables were determined using a computerised, semi-automatic video match-analysis image recognition system (ProZone®). We computed the mean for each variable from the set of repeat matches for each referee (range: 9 to 23 matches). The technical and physical predictor variables were then regressed on the log-transformed RPE outcome in the n=17 cases. The magnitude of the effect of predictors was represented by the partial correlation (the square root of the fraction of variance explained by the predictor after adjustment for all other predictors [Hopkins et al., 2009]). Results Regression diagnostics revealed no degrading collinearity between predictors. The predictor variables combined explained 76% of the variance in match RPE scores (R=0.91, adjusted R-squared=0.76). Partial correlations were -0.88 for distance from the ball, 0.86 for total player high-speed running, 0.75 for match disciplinary points, and -0.55 for total referee high-speed running. These effect sizes are large to very large. For example, after controlling for match physical demand, an increase in disciplinary points equivalent to awarding a yellow card is associated with an increase in RPE of 17%. Discussion The results of this preliminary investigation demonstrate for the first time that elite soccer referees' global match RPE scores are influenced by both the technical and physical match demand. ### EFFECTS OF PRELOADING EXERCISE INTENSITY ON PHYSICAL AND COGNITIVE PERFORMANCE IN SOCCER

FERRAUTI, A.1, OH, S.1, DRÖSCHER, S.1, MIERAU, A.2, THEVIS, M.3, THOMAS, A.3, FERNANDEZ-FERNANDEZ, J.1

1:FACULTY OF SPORTS SCIENCES, RUHR-UNIVERSITY BOCHUM; 2,3:GERMAN SPORT UNIVERSITY COLOGNE

Introduction Preloading activities of different intensities and with varied time span prior to competition are usually arranged by coaches to optimize the coordinative, physical and cognitive performance of players during the early stages of a soccer match. To the best of our knowledge there have been no studies, which investigate these expected effects under controlled conditions. In a first approach we compared the short and mid-term effects of different preloading exercises during the morning when kick-off is in the afternoon. Methods 12 male, amateur soccer players participated in the study (24.1±5.5 yrs; 179±9.3 cm; 76.3±9.1 kg). After laboratory testing (VO<sub>2</sub>max 50.6±2.8 ml•kg<sup>-1</sup>•min<sup>-1</sup>, HRmax 192.3±7.6 min<sup>-1</sup>), players completed three experimental Sessions (from 7 am to 4 pm), spaced at least one week apart. In a balanced cross over design players either completed no morning preloading exercise (CON), a moderate preloading (MOD) or a high intensive preloading (INT) at 10 am, each followed by the Bangsbo soccer specific endurance field test (Bangsbo & Lindquist, 1992) at 3 pm. Preloading was either moderate (MOD: 4x2 min in a 10x10 m pitch, 10x10 m sprint, 20 s recovery) or intensive (INT: 4 x 4 min in a 10x20 m pitch, 10 x 20 m sprint, 20 s recovery) and consisted in small side games followed by intermittent sprints. Subjects had a standardized breakfast (7 pm), snack (9 pm) and lunch (1 am), respectively. During MOD (plus 350 kcal) and INT (plus 600 kcal) an adjusted extra caloric cost was administered. In the morning (M), after the preloading (post P) and before endurance testing in the afternoon (pre T) Critical Flicker Fusion Frequency (CFF), reaction time (RT) and the urine concentrations of adrenaline (A) and noradrenaline (NA) were measured. Results Preloading physical demands and endocrine responses were significant higher during INT (HRmax: 87.2±2.9 %, LA: 8.1±5.3 mmol•L<sup>-1</sup>, A: 83.8±58.9 ng ml<sup>-1</sup>) compared to MOD (HRmax: 71.0±6.0 %, LA: 2.7±1.6 mmol•L<sup>-1</sup>, A: 54.3±14.9 ng ml<sup>-1</sup>, p<0.05) and CON (A: 21.7±16.8 ng ml<sup>-1</sup>, p<0.05). RT and CFF improved significantly from M to post P and pre T on all test days while no significant ANOVA interaction between measurements and interventions was calculated. Distances covered during the Bangsbo endurance tests tended to be lower after INT (2068±85 m) and were higher after MOD (2111±142 m) while no significant differences were found. Discussion Morning preloading intensity seems to have no significant impact on cognitive performance and soccer specific endurance during afternoon soccer matches despite significant physiological and endocrine short term effects. We recommend players to develop and to follow their individual routines for match play preparation. This has to be considered by coaches. References Bangsbo J, Lindquist F. (1992). Comparison of various exercise tests with endurance performance during soccer in professional players. *Int J Sports Med* 13, 125-132.

### TRAINING OF PERCEPTUAL-COGNITIVE SKILLS IN OFFSIDE DECISION MAKING

PUT, K.

K.U.LEUVEN

TRAINING OF PERCEPTUAL-COGNITIVE SKILLS IN OFFSIDE DECISION MAKING Put, K.(1); Catteeuw, P.(1); Gilis, B.(1); Jaspers, A.(1); Wagemans, J.(2) & Helsen, W.(1) (1)Department of Biomedical Kinesiology, Perception and Performance Lab, K.U.Leuven (2)Department of Psychology, Laboratory for Experimental Psychology, K.U.Leuven Introduction In association football, the flash-lag effect (FLE) is a viable explanation for erroneous offside decision making (1,2). Recently, it has been demonstrated that off-the-field perceptual-cognitive training programmes are favourable to learn assistant referees (ARs) to better deal with the perceptual consequences of this spatio-temporal illusion (3). The aim of the present study is to investigate the effectiveness of two different off-the-field training formats (video simulations – computer animations) to improve offside decision making. Methods Forty Belgian elite ARs, active in the first division in Belgium voluntarily participated in the present study. In the pre- and post-test, the ARs judged 80 offside situations (2 x 20 video simulations and 2 x 20 computer animations). Based on their pre-test results, two training groups and one control group were created. The video-format training group (n=9) and the computer-format training group (n=9) participated in 4 training sessions of either 30 video simulations or 30 computer animations, respectively, both with extended feedback. The control group (n=22) was only exposed to the pre- and post-test. Response accuracy and type of error (i.e. flag errors or non-flag errors) were analysed in the two test sessions. Results First, response accuracy improved and flag errors decreased for both training groups from pre- to post-test. Second, the video-format training group assessed both the video simulations and computer animations more accurately in the post-test. Similar results were found for the computer-format training group. Thus, training in one format also resulted in a performance improvement in the other format. Discussion The results of the present study clearly show that perceptual-cognitive skill training can overcome the difficulties in offside decision making. Therefore, off-the-field offside training sessions should be considered as part of practice routines of ARs to optimize the perception and decision-making processes in their real matches. ## PREDICTING CAREER SUCCESS IN AFL FROM DRAFT CAMP RESULTS, DRAFT ORDER, AND PHYSICAL MATCH PARAMETERS: IS THE AFL DRAFT CAMP WORTHWHILE?

BURGESS, D., NAUGHTON, G., HOPKINS, W.

LIVERPOOL FOOTBALL CLUB

Purpose In Australian Rules Football (AFL) one of the most important perceived predictors of career success is the National Draft Camp. This 4 day event requires Under 18 draftees to complete numerous physical, psychological, medical and skill-based assessments. Prior to this camp, the National Under 18 tournament provides scouts with an opportunity to subjectively assess players in a competitive environment. This project compared 5 year career success in the AFL with physical draft camp tests, final draft selection order and objective analysis of match physical performance using GPS technology. Methods TrakPerformance Software and Global Positioning System (GPS) technology were used to analyse the movement of players, ball speed and game statistics of Under 18 AFL players during competitive matchplay. Physical data was collected over a 2 year period at the National Draft Camp. Both sets of data, along with final draft selection order, were compared to 5 year career success in senior AFL using innovative mathematical modelling. Results Clear, large, positive interactions were observed between various match variables and 5 year career success (percentage of time spent sprinting, distance travelled per minute and distance sprinted per minute). A clear, small positive interaction was observed between draft order and 5 year career success. No clear interactions were observed between any physical draft camp tests and 5 year career success. Conclusions Five year career success in senior AFL is best predicted using physical parameters assessed during match play. The more traditional practice of predicting success using physical draft camp parameters appears flawed

### OP-PM07 Nutrition: Carbohydrate

#### CARBOHYDRATE INGESTION DURING ENDURANCE RUNNING ON INFLAMMATION AND HEPcidIN LEVELS

SIM, M.1, PEELING, P.1,2, DAWSON, B.1, LANDERS, G.1, WIEGERINCK, E.3, SWINKELS, D.3, TOWNSEND, M.4, TRINDER, D.1

1: THE UNIVERSITY OF WESTERN AUSTRALIA (PERTH, AUSTRALIA), 2: WESTERN AUSTRALIA INSTITUTE OF SPORT (PERTH, AUSTRALIA), 3: RADBOUD UNIVERSITY (NIJMEGEN, NETHERLANDS), 4: PATHWEST (PERTH, AUSTRALIA)

Introduction Exercise has been shown to increase interleukin-6 (IL-6) levels, resulting in the up-regulation of the iron regulatory hormone, hepcidin (Peeling et al., 2009). Elevated hepcidin levels may decrease iron absorption and recycling (Nemeth et al., 2004), potentially causing athletic induced iron deficiency. However, separate studies have shown that carbohydrate (CHO) consumption during exercise can depress IL-6 levels (Nieman et al., 1998). As such, this study set out to determine the effect of CHO consumption during endurance running on post-exercise IL-6 and hepcidin levels. Method Eleven well-trained male endurance runners completed a graded exercise test, and two experimental trials in a randomized order. The two experimental trials consisted of a 90 min run at 75% of the peak oxygen uptake velocity ( $\dot{V}O_{2peak}$ ), while consuming a solution with either 6% CHO or a placebo (PLA) equivalent at 3 ml.kg<sup>-1</sup> every 20 min. Serum IL-6, free hemoglobin (Hb), haptoglobin (Hp), hepcidin and iron parameters were assessed throughout the post-run recovery period. Results Serum iron and IL-6 were significantly elevated immediately post-run in both CHO and PLA ( $p \leq 0.05$ ), with no significant difference recorded between trials. Serum free Hb increased and Hp decreased significantly immediately post-run in both conditions ( $p \leq 0.05$ ). Serum soluble transferrin receptor levels were significantly below baseline at 3 and 24 h post-run in both conditions ( $p \leq 0.05$ ). Serum hepcidin concentration recorded 3 h post-run in both conditions was significantly elevated ( $p \leq 0.05$ ), and had returned to baseline by 24 h post-run ( $p \leq 0.05$ ). Discussion The use of a 6% CHO solution at 3 ml.kg<sup>-1</sup>.20min<sup>-1</sup> during endurance running did not attenuate the inflammatory response and subsequent increase in serum hepcidin levels during the post-run recovery period. As such, elevated hepcidin levels may reduce the bioavailability of iron, causing a reduction in erythropoiesis up to 24 h post-exercise. #### CARBOHYDRATE INGESTION ENHANCES MAXIMAL SPRINT PERFORMANCE IN COMPETITIVE MALE CYCLISTS

CHONG, E., GUELF, K.J., FOURNIER, P.A.

THE UNIVERSITY OF WESTERN AUSTRALIA

Introduction There is evidence that ingesting carbohydrates (CHO) during exercise or using a CHO mouth rinse can improve 1-h high-intensity exercise performance (Chambers et al., 2009; Rollo et al., 2010), thus suggesting that the ergogenic effect of CHO is mediated by the stimulation of the sweet taste receptors in the oral cavity. In contrast, we recently showed that CHO mouth rinsing has no effect on sprint performance (Chong et al., 2010). Given the presence of sweet taste receptors in the upper intestine (Dyer et al., 2005), the primary aim of this study was to investigate whether the combined stimulation of the taste receptors in the oral cavity and gut can improve the performance of a maximal sprint. Methods Twelve competitive male cyclists ( $\dot{V}O_{2peak}$  57.8 $\pm$ 4.7 mL.kg<sup>-1</sup>.min<sup>-1</sup>; mean  $\pm$  SD) each ingested and rinsed their mouth with 100 mL of one of the following solutions on separate occasions and following a randomised double blind counterbalanced design; (a) 10% glucose solution [Glu], (b) 0.05% aspartame solution [Asp], (c) 9.1% maltodextrin solution [Mal], or (d) water [Wa] as a control, followed by repeatedly mouth rinsing with 11 boluses of 15 mL of the same solution. Then, each participant performed a 30-s maximal sprint effort on a cycle ergometer and performance was assessed. Results The Asp and Mal trials were not significantly different from Wa across all indicators of sprint performance (maximal power output and mean power output,  $p > 0.05$ ). In contrast, the Glu trial improved maximal power output during the sprint effort by 14.7% ( $p < 0.05$ ) compared to Wa and by 9 and 16% ( $p < 0.05$ ) compared to the Asp and Mal trials, respectively. Blood glucose levels increased to a similar extent in response to the Wa and Glu trials. Discussion Our findings suggest that combining the rinsing and ingestion of a glucose solution improves maximal sprint performance. This ergogenic effect is unlikely to be related to sweetness since the Asp trial had no effect on performance despite sweetness matching that of Glu. The benefit of Glu is also unlikely to result from a rise in blood glucose level as Mal resulted in a similar rise but without affecting performance. Given earlier findings from this laboratory that mouth rinsing alone had no effect on maximal sprint performance, we suggest that the ergogenic effect of glucose ingestion on maximal sprint performance is likely to be mediated via the stimulation of the CHO receptors in the upper intestine. ### **EFFECT OF LOW GLYCAEMIC INDEX MEALS ON APPETITE SENSATION AND ENERGY BALANCE OF MALE ADULT ATHLETES**

WU, D.M.Y., ROWLANDS, A.V., WILLIAMS, C.A.

UNIVERSITY OF EXETER

**Introduction** A concept of low glycaemic index (LGI) carbohydrate containing foods which provide higher satiating effects than foods with high glycaemic index (HGI) has emerged recently (Bornet et al., 2007). Consumption of LGI meals may be beneficial for athletes to promote satiety so as to achieve optimal body weight. Therefore, the aim of this study was to investigate the short term effect of GI meals on subjective appetite sensation and energy balance in adult male athletes. **Methods** Fourteen recreationally active males (mean  $\pm$  SD; age  $34.5 \pm 8.9$  y, BMI  $22.8 \pm 2.0$  kg /m<sup>2</sup>) participated in a randomised crossover design with LGI and HGI meals. On each trial day, participants consumed a breakfast in the laboratory, then left one hour postprandially with a food bag containing lunch, dinner and snacks. Subjective appetite sensations were recorded regularly using a visual analogue scale during the first postprandial hour in the laboratory and hourly throughout the trial days. Resting energy expenditure (REE) was measured in the fasted state during both trial days and 24 hr later. Energy intake (EI) and expenditure (EE) of the trial days and 24 hr later were assessed by self-report food intake and accelerometry. The overall calculated GI values for the HGI and LGI meals were  $76.0 \pm 2.8$  and  $39.5 \pm 1.0$  respectively. Energy, macronutrients and the fibre contents; and the caloric density were similar between LGI and HGI at each mealtime. **Results** Participants reported a higher appetite score after the consumption of the LGI breakfast than the HGI breakfast throughout the first postprandial hour in the laboratory ( $p=0.03$ ) and throughout the remainder of the trial day ( $p=0.006$ ). The mean appetite score after 20 minutes for all LGI meals was significantly higher than for the HGI meals ( $34.0 \pm 15.6$  vs  $27.5 \pm 12.6$ ,  $p=0.027$ ). No significant differences were found in the REE, EI and the EE between the corresponding trial days and the post-trial days. **Discussion** These results indicate that in the short term frequent consumption of HGI mixed meals can suppress appetite compared to that of LGI mixed meals which is inconsistent with previous findings. As GI may also depend on the exercise level of participants (Mettler et al., 2007), further investigation of the relationship between GI and appetite for the regulation of food intake in trained athletes is required. These results also indicate the importance of matching the protein, fat and fibre contents relative to the GI values for mixed meals. **References** Bornet FR, Jardy-Gennetier AE, Jacquet N, Stowell J. ### **CARBOHYDRATE SUPPLEMENTATION DURING INTENSE INTERMITTENT TRAINING FOR THREE WEEKS DOES NOT INFLUENCE THE DEVELOPMENT OF THE ENDURANCE CAPACITY AND THE ADAPTATION OF THE FAT METABOLISM.**

MAASSEN, N., KUMMER, O., SHUSHAKOV, V., MAASSEN, M.

MEDICAL SCHOOL HANNOVER

In 1996 Helge et al. showed that the consumption of a diet with  $> 60$  energy % daily during a training period was beneficial for developing the endurance capacity. The results of Hansen et al. (2005) contradict this finding in a way. According to them training in a glycogen depleted state is especially beneficial for the development of the endurance capacity. However, Cluberton et al. (2005) came to the conclusion that not glycogen depletion but reduced glucose availability increases the expression of genes of the fat metabolism. In fact Hanke et al. (2008) showed in muscle cell cultures that the glucose availability was the key factor to shift the metabolic profile to the endurance phenotype. Thus the question emerged: is the customary use of carbohydrates detrimental for the development of the endurance capacity? **Methods:** Each group (Plac and CHO) consisted of 10 males with a mean relative maximal power of  $4.15 \pm 0.7$  W.  $VO_{2peak}$  and endurance capacity was determined in incremental (IC) and constant load tests (EC) before and after the training period. The IC started with a pre-period of 6 min at 100 W. Afterwards power was increased every min by 16.66 W until exhaustion ( $W_{max}$ ). During the IC spirometric data were collected and [Lactate] from a hyperaemized earlobe was determined. The intensity for the EC was 30 % for warming up (6 min) und 80% of  $W_{max}$  (initial IC) to exhaustion. During the constant load tests blood was collected from a cubital vein for determining parameters of the fat metabolism. An additional constant load test was performed at 50%  $W_{max}$  to determine the oxygen on-kinetics. **Intermittent exercise training:** After 10 minutes of warming up with 50% of  $W_{max}$  55 cycles with 100% for 30 s followed by 30 s without breaking force were performed 3 times a week for 3 weeks. **Beverages:** Both groups ingested tap water: in total 26 ml/ kg body weight. In CHO Maltodextrin was added resulting in a concentration of 9.1 weight %. **Results:** The increases in maximum power ( $\pm 2.5$  %) and  $VO_{2peak}$  ( $\pm 1.8$  %) were not significant in both groups. Lactate thresholds did not change significantly. However, the endurance capacity increased by 50% in both groups (each:  $p<0.01$ ). During the low and medium constant intensity tests no change in metabolites, heart rate, ventilation, and RER could be detected. Even at 80% fat metabolites did not change significantly. The time constant of  $VO_2$  (50 %) did not change significantly. **Conclusion:** As the carbohydrate administration and the training had no effect on the aerobic capacity and non the fat metabolites during the EC-tests the increase of the endurance capacity seems to be due to non-metabolic factors.

### **THE EFFECTS OF DIFFERENT DOSES OF CAFFEINE ON ONE HOUR CYCLING PERFORMANCE**

DESBROW, B., BIDDULPH, C., DEVLIN, B., GRANT, G.D., ANOOPKUMAR-DUKIE, S., LEVERITT, M.D.

GRIFFITH UNIVERSITY

**Objectives:** This study investigated the effects of two different doses of caffeine on one hour cycle time trial performance in male athletes. **Design:** Randomised, placebo-controlled, double-blind crossover study design. **Methods:** Sixteen well-trained and familiarised male cyclists (Mean  $\pm$  SD: Age =  $32.61 \pm 8.32$  years; Body mass =  $78.53 \pm 6.0$  kg; Height =  $180.91 \pm 5.53$  cm;  $VO_{2peak}$  =  $60.35 \pm 4.06$  ml·kg<sup>-1</sup>·min<sup>-1</sup>) completed three experimental trials, following training and dietary standardisation. Participants ingested either a placebo, 3 or 6 mg·kg<sup>-1</sup> BM of caffeine 90 min prior to completing a set amount work equivalent to 75% of peak sustainable power output for 60 min. **Results:** Exercise performance was significantly ( $p < 0.05$ ) improved with both caffeine treatments as compared to placebo (4.2% with 3 mg·kg<sup>-1</sup> BM and 2.9% with 6 mg·kg<sup>-1</sup> BM). The difference between the two caffeine doses was not statistically significant ( $p > 0.05$ ). Caffeine ingestion at either dose resulted in significantly higher heart rate values than the placebo conditions ( $p < 0.05$ ), but no statistically significant treatment effects in RPE or plasma [K<sup>+</sup>] were observed. **Conclusions:** A caffeine dose of 3 mg·kg<sup>-1</sup> BM appears to improve cycling performance in well-trained and familiarised athletes. Doubling the dose to 6 mg·kg<sup>-1</sup> BM does not confer any additional improvements in performance.

## INFLUENCE OF CARBOHYDRATE SUPPLEMENTATION ON THE ENERGY METABOLISM DURING INTENSE INTERMITTENT TRAINING

TREFF, B., SCHMOE, T., SCHRADER, M., MAASSEN, M., SHUSHAKOV, V., MAASSEN, N.

INST. FOR SPORTS MEDICINE MEDICAL SCHOOL HANNOVER (MEDIZINISCHE HOCHSCHULE HANNOVER)

During intermittent exercise of high intensity Type II muscle fibres are activated to a large amount. These fibres are relying on glucose as a substrate to a larger extent than type I fibres. Therefore the question arises: can a carbohydrate supplementation shift the energy supply to a larger carbohydrate combustion during exercise. Methods: 11 male subjects (weight: 82.2 kg; height: 1.82 m, relative power: 4.3 W) performed an intermittent exercise test twice; in one trial tap water (4m /kg/15min) was consumed (Plac). In the other trial the same amount of water was ingested, however, Maltodextrin was added to achieve a 9.1 % carbohydrate solution (CHO). The mean intensity during exercise was 50% of the maximum power reached in an incremental test performed as a pre test. Training schedule: warming up with 50 % for 15 min. Afterwards power changed between 100% of the maximum power minus 10 W and 10 W each for 30 s. The intermittent exercise was performed until subjective exhaustion. Afterwards 10 min at 50% to cool down followed. Spirometric data were collected. From the VO<sub>2</sub> and VCO<sub>2</sub> the RER was calculated. For statistical evaluation of the RER during the intermittent exercise period values over 2 min were averaged. Cubital venous blood was sampled to measure the concentration of HCO<sub>3</sub><sup>-</sup>, Lactate, Glucose, Glycerol, Triglycerides, free Fatty Acids and NH<sub>3</sub>. Results: Performance time was not significantly different between the groups. No difference in heart rate and VO<sub>2</sub> between the trials could be detected. Glucose concentration was significantly higher after Maltodextrin administration ( $p < 0.001$ ). During exercise the lactate concentrations were not different between the trials. The increases in Glycerol and free Fatty Acids were larger under Plac (interaction beverage x time  $p < 0.001$ ). For both quantities the maximal concentrations were found during the cool down. RER during the end of the intermittent exercise period was lower under Plac ( $p < 0.001$ ). Plasma HCO<sub>3</sub><sup>-</sup> concentration and total CO<sub>2</sub> in the blood were constant at the late intermittent exercise period. Thus the RER is a valid indicator for a larger contribution of fat to the energy supply during this part of the experiment. NH<sub>3</sub> increased significantly more under Plac ( $p < 0.001$ ). The highest value was reached with the end of the intermittent exercise period. Discussion: Carbohydrate supplementation reduces the fat combustion during exercise even if a large portion of type II fibres are used. It has to be elucidated whether the larger increase in NH<sub>3</sub> is the result of an increased protein catabolism or of an increased AMP-combustion activity.

## DIURNAL VARIATION IN THE MECHANICAL AND NEURAL COMPONENTS OF THE BAROREFLEX

TAYLOR, C.E., ATKINSON, G.1, WILLIE, C.K.2, JONES, H.1, AINSLIE, P.N.2, TZENG, Y.C.3

1LJMU UK, 2UBC CANADA, 3U OF OTAGO WELLINGTON NZ

Introduction Exercise-related measurements of blood pressure (BP) variability and baroreflex sensitivity are prognostic indicators of cardio and cerebro-vascular events. Intriguingly, these events are up to 3.5 times more likely within the first 3 h after waking. Diurnal variation in BP responses to exercise is evident (Jones et al., 2008), yet the importance of baroreflex sensitivity is unclear in this context. We aimed to determine the contribution of the mechanical and neural components of the cardiac baroreflex to diurnal variation in BP control. Given that carotid arterial distensibility shows diurnal variation (Kool et al., 1991), we hypothesised that diurnal variation in baroreflex gain is explained by variability in the mechanical component. Methods In 12 participants (7 male, mean $\pm$ SD age 24.7  $\pm$ 4.0yrs) we measured continuous BP, R-R intervals and carotid artery (CA) diameter during intravenous bolus injections of sodium nitroprusside (SNP) followed by phenylephrine (PE) (modified Oxford method) at 0700 and 1600h. This technique quantifies baroreflex gain for falling BP via SNP (G-down) and rising BP via PE (G-up). Integrated gain was determined by plotting beat-to-beat R-R intervals against systolic BP. The mechanical component was diameter plotted against systolic BP, and the neural component was R-R intervals plotted against CA diameter. A novel analysis method based on linear mixed models (Atkinson et al., 2010) was employed to compare the integrated, mechanical and neural gains between 0700 and 1600h. Results An attenuated ( $P < 0.05$ ) baroreflex gain was found in the morning (G-up= 13.0 $\pm$ 0.6; G-down= 6.3 $\pm$ 0.4 ms/mm Hg) compared with the afternoon (G-up= 15.1 $\pm$ 0.6; G-down= 12.6 $\pm$ 0.4 ms/mm Hg). For rising pressures, the reduced integrated gain in the morning was explained by a smaller ( $P = 0.004$ ) mechanical gain (0.015  $\pm$  0.001mm/mmHg) compared with the afternoon (0.018  $\pm$  0.001mm/mm Hg). However, the reduced falling pressure was explained by a diminished ( $P < 0.0005$ ) neural gain in the morning (256.0  $\pm$  30.6 ms/mm) compared with the afternoon (494.9  $\pm$  48.8 ms/mm). Discussion Our findings explicate the underlying mechanisms of diurnal variation in BP control. We suggest that the high prevalence of cardiovascular events in the morning is due to diminished mechanical transduction of pressure into arterial distension at this time. Interventions (e.g. exercise) targeting enhancement of vascular properties may improve baroreflex function, thus reducing the risk that follows waking and the onset of physical activity. References Jones et al. (2008). Eur J Appl Physiol, 104, 481-489 Kool et al. (1991). J Hypertens Suppl, 9, 108-109 Atkinson et al. (2010). Clin Physiol Funct Imaging, 31, 80-82

## DOES EXERCISE TRAINING INDUCE CARDIAC REMODELING IN HUMANS? A COMPARISON OF RESISTANCE AND ENDURANCE EXERCISE USING MRI TECHNOLOGY.

SPENCE, A.1, NAYLOR, L.H.1, CARTER, H.H.1, DEMBO, L.2, GEORGE, K.3, GREEN, D.J.1,3

1. SSEH (UWA, PERTH) 2. RPH (PERTH) 3. RISES (LJMU, UK)

Introduction An accepted dogma in exercise science is that, due to divergent haemodynamic overloads, endurance training induces eccentric cardiac hypertrophy whereas resistance exercise results in a concentric form of cardiac remodeling. However, this tenet relies solely upon cross-sectional comparisons of athlete groups, often using inappropriate scaling and echocardiographic approaches, which are variable. This is the first prospective, longitudinal, randomised study to evaluate the impact of different exercise training modes on cardiac morphology using gold-standard MRI in healthy humans. Methods Participants were randomly assigned to endurance (ENDUR n=10) or resistance (RESIST n=13) training groups and underwent a supervised, intensive training program followed by a detraining period. Measures included aerobic fitness, muscular strength, cardiac morphology assessed using MRI, and body composition using DEXA. Measures were taken at baseline, 6 mo post-training and 6 wk post-detraining. Results Aerobic fitness increased significantly in ENDUR (45.8 to 49.3 mL.kg.min<sup>-1</sup>,  $P < 0.05$ ) but was unchanged in RESIST. Muscular strength significantly improved in both groups, but to a greater

extent in RESIST ( $27.3 \pm 4.6$  vs  $37.5 \pm 4.9\%$ ,  $P < 0.001$ ). Although total fat mass did not significantly change, total lean mass increased in both groups (RESIST:  $59.7 \pm 2.35$  to  $62.0 \pm 2.2$  kg,  $P < 0.001$ , ENDUR:  $56.9 \pm 2.9$  and  $58.3 \pm 3$  kg  $P < 0.05$ ). Left ventricular mass (LVM) increased significantly following ENDUR ( $112.8 \pm 7.4$  to  $122.7 \pm 6.6$  g,  $P < 0.01$ ) but not in RESIST ( $126.8 \pm 7.7$  to  $130.8 \pm 6.5$  g NS). Similarly, end diastolic volume (EDV) increased 3-fold more in ENDUR ( $134.1 \pm 7.9$  to  $143.1 \pm 7.8$  mL) compared to RESIST ( $147.1 \pm 7$  to  $150.2 \pm 7.1$  mL), although neither change achieved statistical significance. Following detraining, ENDUR aerobic fitness returned to baseline, whereas both LVM and EDV remained somewhat elevated. Discussion This is the first study to incorporate highly accurate MRI technology to assess cardiac adaptation using closely supervised intensive longitudinal exercise interventions. In contrast with accepted wisdom, we observed no evidence in these healthy, young and relatively inactive subjects to support the notion that resistance training induces concentric cardiac hypertrophy. Our data are generally consistent, however, with previous echocardiographic evidence that endurance exercise is associated with increased LVM and EDV. These adaptations were maintained for 6 weeks following exercise cessation. In conclusion, endurance exercise induces cardiac morphological adaptations whereas resistance exercise does not, despite the presence of physiological adaptations in strength and body composition.

### COUPLING OF LEFT VENTRICULAR TWIST MECHANICS AND ARTERIAL HAEMODYNAMICS DURING EXERCISE

STÖHR, E.1, MCDONNELL, B.1, BULL, T.1, COX, J.1, HARRISON, M.1, HOUSTON, R.1, HOWARD, J.1, PHILLIPS, G.1, COCKROFT, J.R.2, SHAVE, R.1

1: UNIVERSITY OF WALES INSTITUTE CARDIFF, UK; 2: WALES HEART RESEARCH INSTITUTE, CARDIFF, UK

**Introduction** During exercise, left ventricular (LV) twist increases and arterial augmentation index (Alx), a measure of arterial wave reflection, is reduced. The reduction in Alx may directly facilitate the enhanced twist, however the interaction between LV twist and Alx has not been examined. To gain insight into the potential coupling of LV twist and wave reflection, the purpose of this study was to examine whether the magnitude of change and also the timings in peak LV twist velocity and Alx from rest to exercise are related. **Methods** We examined 11 healthy males (age:  $22 \pm 2$  yrs; height:  $181 \pm 8$  cm; body mass:  $81.6 \pm 12$  kg) with varied aerobic fitness ( $\text{VO}_{2\text{max}}$  range:  $43.7$ – $62.5$  mL·kg<sup>-1</sup>·min<sup>-1</sup>) both at rest and during supine cycling exercise (~40% peak power). Heart rate, stroke volume and maximal twist velocity were assessed using echocardiography and Alx was assessed using radial applanation tonometry. Alx was calculated as the difference between the second (P2) and first (P1) peak arterial pressure (mmHg) divided by the pulse pressure (mmHg). Data were analysed for the magnitude of change in twist velocity and Alx between rest and exercise. The temporal relationship between peak twist velocity and peak arterial pressure within the systolic period was also examined. Statistical differences were assessed with paired samples t-tests, relationships were determined using Pearson's product moment correlation. **Results** From rest to exercise, heart rate and LV stroke volume increased significantly from  $60 \pm 15$  to  $131 \pm 16$  bpm and  $95 \pm 11$  to  $121 \pm 18$  mL, respectively ( $P < 0.001$ ). Concomitantly, peak twist velocity increased ( $79 \pm 22$  to  $139 \pm 35$  deg.sec<sup>-1</sup>,  $P < 0.0001$ ) while Alx decreased ( $11.1 \pm 0.9$  to  $9.1 \pm 0.5\%$ ,  $P < 0.0001$ ) and the change in both parameters correlated significantly ( $r^2 = .55$ ,  $P < 0.01$ ). Peak systolic pressure shifted from P2 at rest to P1 during exercise, which was paralleled by a temporal shift in peak systolic twist velocity from P2 at rest to P1 during exercise, suggesting a coupling of cardiac mechanics with arterial haemodynamics. Neither the increase in LV twist velocity nor the reduction in Alx was related to  $\text{VO}_{2\text{max}}$  ( $r^2 < .02$ ,  $P > 0.69$ ). **Discussion** This is the first study to show that the increase in LV twist velocity from rest to exercise is related to a reduction in Alx, moreover a temporal relationship between the timing of peak systolic twist velocity and peak systolic pressure was also apparent. These findings provide novel insight into ventricular-arterial coupling suggesting that LV twist mechanics and arterial Alx may work in concert to enhance LV output during exercise.

### DIVERSE PATTERNS OF MYOCARDIAL FIBROSIS IN LIFELONG, VETERAN ENDURANCE ATHLETES

WILSON, M., O'HANLON, R., PRASAD, S., DEIGHAN, A., MACMILLAN, P., OXBOROUGH, D., GODFREY, R., SMITH, G., MA-CEIRA, A., SHARMA, S., GEORGE, K., WHYTE, G.

ASPETAR - QATAR ORTHOPAEDIC AND SPORTS MEDICINE HOSPITAL

**Introduction** – Several case studies have speculated that in the absence of any other cause, life-long repetitive bouts of arduous endurance exercise may result in fibrous replacement of the myocardium, resulting in a pathological substrate for the development of arrhythmias. Despite such speculation only limited evidence exists for exercise-induced myocardial fibrosis in endurance veteran athletes. Consequently, the impact of life-long episodes of intense prolonged exercise, as experienced by veteran endurance athletes is not fully understood. **Aim** – To examine the cardiac structure and function of a unique cohort of documented life-long, competitive endurance veteran athletes (> 50 years). **Methods** – Twelve life-long veteran male endurance athletes (mean  $\pm$  SD [range] age:  $56 \pm 6$  yr [50–67]), 20 age-matched veteran controls ( $60 \pm 5$  y; [52 – 69]) and 17 younger male endurance athletes ( $31 \pm 5$  years [26–40]) without significant comorbidities underwent cardiac magnetic resonance (CMR) imaging with late gadolinium enhancement (LGE) to assess cardiac morphology and function, and to assess myocardial fibrosis. **Results** – Life-long veteran athletes had significantly larger absolute and indexed LV and RV end-diastolic and systolic volumes, wall thicknesses, and LV and RV stroke volumes ( $p < 0.05$ ), together with reduced LV and RV ejection fractions ( $p < 0.05$ ) compared to veteran controls. In 6 (50%) of the veteran athletes, LGE of CMR indicated the presence of myocardial fibrosis (4 veteran athletes with LGE of non-specific cause, 1 probable previous myocarditis and 1 probable previous silent myocardial infarction). There was no LGE in the age-matched veteran controls or young athletes. The prevalence of LGE in veteran athletes was not associated with age, height, weight or BSA ( $p > 0.05$ ), but was significantly associated with the number of years spent training ( $p < 0.001$ ), number of competitive marathons ( $p < 0.001$ ) and ultra-endurance (>50 miles) marathons ( $p < 0.007$ ) completed. **Conclusion** – An unexpectedly high prevalence of myocardial fibrosis (50%) was observed in healthy, asymptomatic life-long veteran male athletes, compared to zero cases in age-matched veteran controls and younger athletes, supporting the role of life-long endurance exercise for the incidence of LGE.

### ALTERED MYOCARDIAL FUNCTION AND CARDIAC BIOMARKERS FOLLOWING MARATHON RUNNING

NEARY, J.P., MACQUARRIE, D.S.

UNIVERSITY OF REGINA, REGINA, SK

**Introduction** Cardiac changes are not often recognized as a health risk after exercise. However, previous research using echocardiography has shown that marathon running alters cardiac performance (i.e. cardiac cycle timing and contractility), but later returns to normal suggesting a transient myocardial dysfunction (George et al 2005, George et al 2008). Furthermore, it has been shown that an interaction between intensity and duration play a critical role in this response (Dawson et al 2003). The primary dysfunction identified is a reduction in

diastolic filling and performance. This study explored changes in cardiac performance before and after a marathon using seismocardiography (SCG), and assessing cardiac biomarkers (Shave et al 2007). Methods Recreational runners with no known cardiovascular disease completed a full marathon (FM; N=19; age=46.3±5.2yr; time=3:49±24 min) or half-marathon (HM; N=6; age=39.7±7.9yr; time=1:52±12 min). A tri-axial SCG device was placed on the sternum of the chest and used to monitor resting cardiac cycle amplitude events, electrocardiography (ECG), and serum samples for cardiac troponin-I (cTn-I; Immunoassay). Resting data was collected before (Pre-M), immediately after (Post-M), and on day 1 (D1), 2 (D2), 3 (D3), and 7 (D7) post-marathon. A 30-sec SCG and ECG was recorded and stored for later analysis (15-22 beats). Computer software was designed to analyse SCG timing events and waveform amplitude (mG) for mitral valve open (MVOamp). Repeated measures ANOVA was used for statistical analysis (p<0.05). Results MVOamp (mG) was significantly reduced Post-M in both FM (33%) and HM (46%). This reduction in MVOamp mirrored increases in cTn-I (291% and 42%, respectively). MVOamp remained significantly reduced in FM runners immediately post (30%), on D1 (29%) and returned to Pre-M values on D2; while HM runners MVOamp return to Pre-M values on D1, but declined on D3 (18%) and D7 (24.8%). cTn-I remained elevated in FM on D1 (169%), D2 (106%), and D3 (50%). cTn-I in FM peaked at D1 (92.5%) and was still 17% higher on D3. Marathon distance (FM vs HM) showed significant main effects for MVOamp and cTn-I, from Pre-M to D7. Discussion There was a significant reduction in diastolic function, as measured by MVOamp, immediately following the marathon and this lasted until at least D2 depending on whether a HM or FM was run. These functional changes also corresponded to changes in cTn-I biomarker. Differences between FM and HM persisted up to D7, suggesting that both exercise duration and intensity contribute to these differences. Our findings suggest the impaired diastole is a transient change in myocardial function lasting up to D7 post-marathon. Finally, waveform amplitude (i.e., contractility) can be monitored with SCG before and after exercise. Dawson et al. Sports Med. 2003; 33:365–80 George et al. J Physiol. 2005; 569:305–13 Shave et al. ## SIX WEEKS RESISTANCE TRAINING HAS NO EFFECT ON LEFT VENTRICULAR STRUCTURE

RICHARDS, J., KERR, C., BISWELL, K., OXBOROUGH, D., GEORGE, K., SCULTHORPE, N.

UNIVERSITY OF BEDFORDSHIRE

SIX WEEKS RESISTANCE TRAINING HAS NO EFFECT ON LEFT VENTRICULAR STRUCTURE Richards, J.I, Kerr, C.I, Biswell, K.I, Oxborough, D.3, George, K.2 and Sculthorpe, N.1 1: UoB (Bedford, UK), 2 : LJMU (Liverpool, UK), 3: UoL (Leeds, UK) Introduction The 'Morganroth Hypothesis' suggests that strength training causes significant increases in left ventricular (LV) wall thickness and thus LV mass due to the high afterload associated with that type of exercise (Morganroth et al., 1975). However it has recently been criticised partially due to a lack of training studies and the fact that heart size may be more closely associated with fat free mass (FFM; Naylor et al., 2008). The initial stages of strength training where afterload on the LV is elevated normally induces strength changes due to neural adaptation with little change in FFM (Moritani and DeVries, 1979). This study aimed to use this as a model to determine if afterload without concomitant changes in FFM would affect cardiac morphology. Methods Eight inactive males (aged 18-20 years; height 179.7 ± 8.4 cm; body mass 79.39 ± 18.84 kg) followed a progressive 6-week resistance training programme designed to increase strength but not FFM. Interventricular septal wall (IVS), LV internal dimension (LVD) and LV posterior wall (PW) measurements were assessed from M-mode echocardiograms (Vivid 7, GE Healthcare) at baseline and after training. FFM was estimated via air displacement plethysmography (BodPod, Life Measurement Inc.). Resting HR and blood pressure were assessed via standard techniques (MI-5, Omron) strength was assessed weekly by 1 repetition maximum (RM) prediction (Brzycki, 1993) of bench press and squat. VO2max was assessed at baseline and after training to ensure any cardiac adaptation was not due to improvements in aerobic capacity. Results Training did not increase FFM or VO2max. Bench press 1RM increased by 9 kg (P=0.005) and squat 1RM increased by 19 kg (P=0.001) post-training. There was no change in IVS (1.13 ± 0.08 to 1.10 ± 0.16cm; P>0.05), LVD (5.08 ± 0.4 to 5.16 ± 0.48cm; P>0.05) and PW (1.07 ± 0.1 to 1.08 ± 0.12 cm; P>0.05). Discussion As anticipated, 6-weeks of resistance training increased strength but not FFM and is thought to be due to neuromuscular adaptation (Moritani and DeVries, 1979). The afterload induced by the resistance exercise however, did not bring about measurable changes in cardiac dimensions. This is in contrast to Morganroth et al (1975) and suggests that increased afterload may not be a potent stimulus for cardiac adaptation. References Brzycki M. (1993). ### OP-BN04 Balance and Stability 1

#### POSTURAL BALANCE AND RIFLE STABILITY IN HIGH AND LOW LEVEL BIATHLETES

SATTLECKER, G., LINDINGER, S., BUCHECKER, M., PFUSTERSCHMIED, J., MÜLLER, E.

UNIVERSITY OF SALZBURG

Introduction Biathlon shooting, as well as the athletes' strategies, motor and mental shooting skills, developed remarkably during the last two decades (personal communication). A few studies demonstrated that the quality of 1) postural balance (Sattlecker et al. 2007; Era et al. 1996), 2) rifle/gun stability and vertical movement of the aiming point (Mononen et al. 2003; Zatsiorsky & Aktov 1990) and 3) triggering and shooting score (Sattlecker et al. 2007) differentiate shooters of various skill levels. The aim of the current study was to focus on biathlon specific stability as the main factor of shooting performance. It was hypothesized that biathletes with high shooting scores show lower postural and rifle sway in all directions. Methods Twenty two biathletes of various levels were tested in an indoor measure station. During 40 shots (individual rhythm, without physical load), the postural balance (FITRO SWAY CHECK, 100 Hz) and the rifle stability (8 cam VICON system, 100 Hz) were measured. Rifle and postural (COP) stability were defined by medio-lateral [x], anterior-posterior [y], vertical [z] and total 1) path length (PL), 2) mean velocity (MV), 3) excursion (EX) and 4) standard deviation (SD) within 0.6/0.3 seconds before firing. A discriminant analysis was used to distinguish between high and low score performers (P<0.05, Pooled correlations - discriminating variables canonical discriminant functions, r = coefficient). Results Postural balance: For all variables except Ply\_0.3s and MVy\_0.3s, the two groups showed significant differences with lower values (P<0.05) for high scorers. Stepwise discriminant analysis indicated SDy\_0.6

/ 0.3s ( $r = 0.58$  and  $0.51$ ) and  $EXy_{0.6s}$  ( $r = 0.50$ ) as the most distinguishing variables. Rifle stability: Medio-lateral ( $x$ ; 0.3 & 0.6 s) PL, MV, EX, as well as SD were lower in high scorers ( $P < 0.05$ ) along with lower values for seven other variables (anterior-posterior [ $y$ ], vertical [ $z$ ], total).  $PLx_{0.6}$  / 0.3s ( $r = 0.24$  and  $0.28$ ) and  $EXx_{0.6s}$  ( $r = 0.23$ ) were found to differentiate most clearly between the groups. Discussion & Conclusion High score performers are characterized by lower and slower 1) body sway (all directions) and 2) rifle sway in medio-lateral direction. The most discriminating factors were 1) SD and EX of COP in shooting direction and 2) rifle PL and EX across the shooting direction. The results of this study recommend focussing on the previously mentioned factors in biathlon shooting training. However, they also bring to mind topics that require further studies such as 1) the intercorrelation between rifle and body sway, 2) the influence of foot/ski position and 3) the status of stabilizing musculature on sway, among others. ## THE SEVERITY OF EXPERIMENTALLY INDUCED PAIN INFLUENCES MUSCULAR PERFORMANCE DURING MAXIMAL VOLUNTARY ISOMETRIC KNEE EXTENSOR CONTRACTIONS

WING, A.E.1, JONES, P.G.W.2, CAMPBELL, J.A.1, KAY, A.D.1

1: UON (NORTHAMPTON, UK), 2: UOD (DERBY, UK)

Introduction Experimental pain has been shown to decrease maximal muscular performance (Ervilha et al., 2004) with evidence to suggest that motor unit firing rate is inversely correlated to perceived pain intensity when pain is induced via invasive hypertonic saline injections (Farina et al., 2004). The aims of the present study were to examine the influence of the severity of pain induced by a non-invasive gross pressure device (GPD) on muscular performance in the lower limb. Methods Thirty-one healthy male participants (mean  $\pm$  SD; age =  $32.7 \pm 12.3$ yr, height =  $1.8 \pm 0.1$ m, mass =  $85.3 \pm 12.1$ kg) volunteered for the study after giving written, informed consent, with ethical approval granted by the University of Northampton's ethics committee. Isometric knee extensor joint moment and electromyographic (EMG) activity of the vastus lateralis (VL) and semitendinosus (ST) muscles were measured during maximum voluntary isometric contractions (MVC) within control and three experimental conditions (100%, 200% and 300% of pain perception threshold). A repeated measures ANOVA determined significance between conditions; post-hoc analysis with Bonferroni correction determined the location of any significant differences. Statistical significance was accepted at  $p < 0.05$  for all tests. Results Mean isometric knee extensor moment significantly declined ( $p < 0.05$ ) in all conditions compared with control and 100% pain perception threshold conditions, with greater mean reductions apparent as the severity of pain increased. However, no significant difference existed between 200-300% conditions ( $p > 0.05$ ). Similar significant reductions ( $p < 0.05$ ) were evident within EMG VL and ST data, reflective of the changes in force. Discussion Increasing levels of pain resulted in greater mean decreases in force and EMG data, however when pain perception threshold increased above 200%, no further significant reductions occurred. Unlike previous invasive methods using saline injections into the target muscle (Farina et al., 2004), the present study used a GPD to induce pain remote from the muscles responsible for force production and therefore, could not influence muscle mechanics or physiology. The present VL EMG data reveal a concomitant reduction in neuromuscular activity reflective of the changes in force. This data in conjunction with the methods employed, are suggestive of neurological impairment as the likely cause of reductions in force; however, the location (spinal or supra-spinal) remains unknown and should be investigated further. ## THE INFLUENCE OF VARYING ACCELERATION ON KINETICS, KINEMATICS AND ELECTROMYOGRAPHIC ACTIVITY DURING REACTIVE JUMPS

KRAMER, A., RITZMANN, R., GRUBER, M., GOLLHOFFER, A.

ALBERT-LUDWIGS-UNIVERSITÄT FREIBURG

THE INFLUENCE OF VARYING ACCELERATION ON KINETICS, KINEMATICS AND ELECTROMYOGRAPHIC ACTIVITY DURING REACTIVE JUMPS Kramer, A.1, Ritzmann, R.1, Gruber, M.2, Gollhofer, A.1 1: University of Freiburg (Germany); 2: University of Konstanz (Germany) Introduction: It has been shown that the stretch shortening cycle (SSC) is essential for many types of human movement. Several studies have analyzed the influence of parameters like ground contact time, muscle preactivation or additional weight on the SSC, in order to define a range where the SSC's energy-storage potential - and therefore the efficiency of the movement - is maximized. One important factor that determines how much energy can be stored and then released during the SSC is the load on the tendomuscular system: if it is too high, the contact and coupling time is too long for a storage of energy (Gollhofer & Kyröläinen 1991). This load is mainly determined by the velocity of the jumper and his mass, but also by the acceleration, which does not only affect the load, but potentially also the motor program (via its effect on the vestibular system). The aim of the present study was to assess the influence of the acceleration on the ground reaction force, the rate of force development, the ground contact time, the joint angle progression, the leg stiffness and the muscle activity during reactive jumps. Methods: Ground reaction forces, kinematic and electromyographic (EMG) data of 20 healthy subjects were recorded during reactive hopping in a sledge jump system for seven different acceleration levels: three acceleration levels lower than normal gravity (0.7g, 0.8g, 0.9g), one with gravitational acceleration (1g) and three with higher acceleration (1.1g, 1.2g, 1.3g). Results: Increasing the acceleration from 0.7g to 1.3g resulted in increased peak forces (+15% when comparing the value at 1.3g to the one at 0.7g), longer contact times (+10%), increased muscular activity (+7% to +87%, depending on the muscle), an increased momentum (+28%), unchanged leg stiffness and increased joint excursions in the ankle and knee joints (+3°). Discussion: For the first time, the present study allowed the assessment of the influence of the acceleration on the jump pattern under almost natural movement conditions. The main finding was that the neuromuscular system tried to maintain a high leg stiffness by adjusting the other parameters, such as the movement amplitudes in the joints or the activation of the leg muscles. Furthermore, with this jump system, reactive jumps with short ground contact times were possible in a wide acceleration range. This might be meaningful both for rehabilitation purposes where reduced accelerations could be used to retrain natural movement patterns under reduced load conditions, and for training regimens where higher accelerations would increase the load while still allowing the correct execution of the intended movement. ## TRAINING THE CORE IN CHILDREN WITH CEREBRAL PALSY USING COMPUTER GAMES: A SENSITIVITY ANALYSIS OF ITS IMPACT ON WALKING

FOSTER, R.J.1, HAWKEN, M.B.1, HOLMES, G.2, BUTLER, P.3, BARTON, G.J.1

1:RISES (LJMU, UK), 2:NWIMAC (UK), 3:TMC (UK).

Reduced selectivity of the core (trunk & pelvis) can lead to difficulties in walking in children with Cerebral Palsy (CP), impacting upon activities of daily living. The Gait Deviation Index (GDI) (Schwartz & Rozumalski, 2008) and Movement Deviation Profile (MDP) (Barton et al., 2010) express the deviation of gait from normality as a single discrete value. In addition, the MDP enables a sensitivity analysis of the entire gait cycle, with the potential to indicate which joints contribute most to the deviations. We aimed to explore whether a virtual reality (VR) game designed to train selectivity of the core can improve walking, comparing the GDI and MDP as outcome measures of walking. One child with CP diplegia (10yrs) was trained on the VR game 'The Goblin Post Office' twice a week for 6 weeks. Game speed increased as a function of performance, controlled by a psychophysical algorithm (PEST) (Macmillan & Creelman, 2005), used to determine changes in selectivity of the core during the VR game. Nine gait curves of the pelvis, hip, knee and ankle were measured using a motion capture system to calculate GDI and MDP values before and after intervention. To conduct the sensitivity analysis pelvic, hip and knee/ankle variables (3 groups) were systematically eliminated from the MDP calculation to assess the influence each group had on the outcome. There was a significant increase in game speed in response to training ( $t_{10} = -9.836$ ,  $p < 0.0005$ ), with a mean increase of  $32.6 \pm 11.0$  m/s. There was minimal change in GDI or MDP mean as a result of intervention (GDI: before=75.8; after=75.4, MDP: before=20.8°; after=23.2°). Sensitivity analysis revealed minimal deviation from normality when considering pelvic and knee/ankle angles combined (normal = 6.9°, before = 9.8°, after = 11.3°). Hip and pelvic (normal=5.9°, before=14.4°, after=16.4°) or hip and knee/ankle angles (normal=9.0°, before=19.5°, after=21.0°) combined produced greater deviations from normality for both before and after MDP values. Improvements in game speed suggest VR game play improves selective control of the trunk and pelvis. No change in GDI and MDP implies that improvement in selectivity does not transfer to global changes in walking. Sensitivity analysis revealed hip angles had the greatest effect on deviations from normality using the MDP, suggesting the MDP is sensitive enough to identify problematic areas in a patient's walking. Evaluating activities of daily living (stepping, sit-to-stand, reaching) could be considered as future methods for assessing changes in response to VR training. ## COGNITIVE DEMAND OF REACTIVE AND PREDICTIVE RESPONSES TO GAIT PERTURBATIONS IN YOUNG AND ELDERLY ADULTS

MERSMANN, F., BOHM, S., BIERBAUM, S., DIETRICH, R., ARAMPATZIS, A.

HUMBOLDT UNIVERSITY BERLIN

Introduction A growing body of evidence strongly suggests the involvement of high-level processing in the modulation of reactive and predictive balance adjustments. However, the effect of a concurrent cognitive task on postural responses to unexpected gait perturbations and predictive adjustments during repeated exposure has not been investigated thus far. Methods Thirty-two young (mean age 27 yrs) and 27 elderly (mean age 69 yrs) male subjects participated in the present study and were randomly assigned to either control or dual task group. The subjects performed 18 gait trials on a gangway with alternating surface and surface-information conditions. After baseline assessment (Base) the surface was changed from hard to soft without knowledge of the subjects, inducing an unexpected perturbation (s1). Before (H1), between (H2) and after (H3) the adaptation phases (early, late) performed aware of the soft surface, unexpected hard surface trials represented after effects (i.e. predictive adjustments). Throughout the gait protocol the dual task groups performed a concurrent cognitive task, adjusted in the level of difficulty. The subjects executed respective mathematical operations according to the type of auditory cue and verbalized the result. Whole body kinematic data was recorded to quantify dynamic stability based on the 'extrapolated center of mass' concept proposed by Hof et al. (2005). Main findings and conclusions Irrespective of age or cognitive load, the margin of stability (MoS) decreased significantly ( $p < 0.001$ ) at touchdown of the recovery leg following the unexpected perturbation compared with baseline (Base: -4.63cm; s1: -13.32cm). Recovery performance improved in the early and late adaptation phase. Correspondingly the MoS at touchdown of the disturbed leg increased significantly ( $p < 0.001$ ) in the trials representing predictive adjustments (Base: -4.2cm; H1: -1.3cm; H2: -0.6cm; H3: -1.1cm). The cognitive task performed by the dual task groups neither affected reactive balance recovery, nor subsequent fast predictive adjustments. However, the unexpected perturbation (s1) induced a deterioration of cognitive task performance in the dual task groups. The number of faults (Base: 0.13; s1: 0.48;  $p = 0.02$ ) increased significantly in both groups, response times only in the young group (Base: 1.36s; s1: 1.91s;  $p = 0.007$ ). This indicates an involvement of cortical areas in the modulation of the postural response. Predictive gait adjustments, on the other hand, did not interfere with the concurrent cognitive task, suggesting that age-related cognitive impairments do not affect locomotor adaptational responses during disturbed walking, even when additional cognitive load is applied. ## DOES A HIGHER MUSCLE FORCE OUTPUT REQUIRE MORE PRIMARY MOTOR RESOURCES? -AN EEG STUDY

BRÜMMER, V., VOGT, T., SCHNEIDER, S.

GERMAN SPORT UNIVERSITY COLOGNE

Introduction: Recently, a new method to investigate changes in brain cortical activity during whole-body exercise up to maximal effort has been developed. Using electroencephalography (EEG) in combination with low resolution brain electromagnetic tomography (LORETA) we were able to display elevated primary motor cortex activity with increasing exercise intensity during a dynamic incremental bicycle exercise test until subjective exhaustion (Brümmer et al. 2011). A second study intended to proof whether this is also true for increasing efforts during an isometric strength task. Based on the prior study it was expected to observe increasing primary motor cortex activity with increasing exercise intensity. Methods: Twelve subjects were asked to perform isometric leg extensions randomly at 20%, 40%, 60% and 80% (calculated on the basis of 3 individual maximal voluntary contractions) for 20 sec. A target line indicated the particular force level which participants were asked to hold as accurate as possible. EEG was recorded during the 20 sec of the four different practice trials as well as for 20 sec prior to the test under resting conditions (rest). Current density of EEG was analyzed and localized using LORETA in several regions of interest related to motor, sensory and behavioral processes. Results: Compared to the rest condition current density was found to be higher during the isometric force task in brain areas related to motor and sensorimotor processes such as the primary motor and sensory cortex, the somatosensory association and the premotor cortex. With increasing efforts activity of motor and sensory brain areas, but also frontal brain regions known to be involved in emotional and behavioral processes were found to be elevated.

Discussion: These findings confirm that several motor and sensory cortexes are active during the execution of an isometric strength task and that not only primary motor cortex activity is elevated with increasing exercise intensity. Additionally, brain regions related to emotional and behavioral processes showed enhanced activity at higher strength levels, which might be a sign of a more complex brain network at higher efforts.

### OP-PM15 Training and Testing: High Intensity Training

#### INDICES OF METABOLIC HEALTH ARE SIMILAR FOLLOWING INTENSE-INTERVAL OR ENDURANCE CYCLING TRAINING

PARR, E.B.1, LUCAS, S.J.E.1, STAVRIANEAS, S.2, GRAHAM, M.J.1, REHRER, N.J.1, COTTER, J.D.1

1: UO (DUNEDIN, NEW ZEALAND); 2: WU (OREGON, USA)

Introduction Recent research has shown the effectiveness of repeated high intensity exercise (RHIE) for increasing muscle carbohydrate stores and fat utilisation during endurance exercise (Burgomaster et al., 2008), and RHIE may be a time-efficient strategy for health promotion (Gibala, 2007). Recently, 12-wk high-intensity interval running training was shown to be less effective than endurance running for cholesterol levels, but as effective for glucose tolerance (Nybo et al., 2010). The purposes of this study were to examine whether 8-wk RHIE training, relative to endurance training, improves energetics of aerobic exercise and blood markers of metabolic health. Methods Twelve healthy, untrained adults (5 males, 7 females; age  $23 \pm 4$  y;  $\text{VO}_{2\text{max}}$   $38 \pm 5$  mL/min/kg) completed two 8-wk training blocks of RHIE or endurance (END) cycle ergometer training in a randomised cross-over design with 7-wk washout between blocks. RHIE training progressed from four to six 30-s intervals 3 d/wk, while END training progressed from 40 to 60 min at 65%HRmax 5 d/wk, as previously reported (Burgomaster et al., 2008). Participants' metabolic function was assessed at rest (blood samples) and during cycling tests ( $\text{VO}_2$  and Respiratory Exchange Ratio (RER)) before and after each training block. The tests were an incremental  $\text{VO}_{2\text{max}}$  test and, ~3 h following a standardised breakfast on a separate day, 50-min cycling at 65% pretraining  $\text{VO}_{2\text{max}}$ . Results  $\text{VO}_2$  max increased to a similar extent following END and RHIE ( $11 \pm 6\%$ ,  $16 \pm 10\%$  resp.; 95%CI:  $5 \pm 8\%$ ). RER during submaximal exercise fell similarly across blocks: by  $0.03 \pm 0.04$  (END) and  $0.05 \pm 0.04$  (RHIE); CI:  $0.01 \pm 0.03$ . Fasting blood glucose tended to increase after RHIE training ( $0.31 \pm 0.59$  mmol/L), and decrease after END training ( $-0.08 \pm 0.33$  mmol/L; CI:  $0.38 \pm 0.43$ ). Triacylglycerol (TAG) concentration decreased across RHIE ( $-0.16 \pm 0.37$  mmol/L) and increased across END ( $0.20 \pm 0.43$  mmol/L), such that training type had a differential effect (CI:  $0.36 \pm 0.35$ ). However, 8-wk of either training did not alter fasting cholesterol or insulin concentrations. Discussion Low volume, high-intensity training was as effective as traditional endurance training in improving fuel utilisation during endurance exercise. Resting blood glucose and TAG concentrations responded differently to the two training types, but these effects were small and not matched by cholesterol or insulin changes. #### COMPARISON OF SHORT-TERM SPRINT INTERVAL TRAINING AND TRADITIONAL EXERCISE RECOMMENDATIONS IN SEDENTARY OVERWEIGHT/OBESE MEN

SKLERYK, J., KARAGOUNIS, L., HAWLEY, J.A., SHARMAN, M.J., WATSON, G., LAURSEN, P.B.

EDITH COWAN UNIVERSITY

COMPARISON OF SHORT-TERM SPRINT INTERVAL TRAINING AND TRADITIONAL EXERCISE RECOMMENDATIONS IN SEDENTARY OVERWEIGHT/OBESE MEN Skleryk JR1, Karagounis L2, Hawley JA2, Sharman MJ1, Watson G1 and Laursen PB1, 3, 4 1Edith Cowan University (AUSTRALIA), 2RMIT University (AUSTRALIA), 3New Zealand Academy of Sport (NEW ZEALAND), 4AUT University (NEW ZEALAND) Introduction While exercise is essential to reduce chronic disease risk, many individuals do not adhere to exercise recommendations, with the primary reason being 'lack of time.' In recreationally trained individuals, short-term sprint interval training (SIT) has been shown to induce metabolic and performance adaptations that parallel those of traditional exercise recommendations (TER), and require considerably less time commitment (1, 2). However, little is known about the effectiveness of short-term SIT in sedentary overweight individuals. This study compared the effects of 2-weeks of SIT and TER on metabolic and health-related markers in sedentary, overweight/obese men. Methods Sixteen men ( $37.8 \pm 5.8$  y; BMI  $32.8 \pm 4.7$  kg•m<sup>-2</sup>) were evenly assigned to either a SIT or TER group. Over a 2-week period, 6 sessions of 8-12 x 10 s supramaximal cycle sprints (3 sessions per week) were performed in SIT, while TER consisted of 10 sessions of cycling for 30 min at 65%  $\text{VO}_{2\text{peak}}$  (5 sessions per week). Fasting plasma glucose, insulin, nonesterified fatty acids (NEFA), homeostasis model assessment of insulin resistance (HOMA-IR), body composition and peak oxygen consumption ( $\text{VO}_{2\text{peak}}$ ) were assessed at baseline and 72 h after the final training bout. Muscle biopsy samples were taken from the vastus lateralis at the same time points, and analysed for proteins related to glucose uptake and mitochondrial function. Paired t-tests were used to compare the pre and post-training measurements within each group, and independent t-tests were used to compare changes from pre to post-training between groups. Results No significant changes in BMI, body composition,  $\text{VO}_{2\text{peak}}$ , fasting plasma glucose, insulin and HOMA-IR were observed from pre to post training, either within groups, or between groups. A decrease ( $p < 0.05$ ) in fasting plasma NEFA was found only in the TER group post training. Muscle biopsy analysis revealed that protein expression of specific markers (AS160, COX II, COX IV, GLUT-4, Nur77 and SIRT1) did not change in either training group. Discussion It appears that the response of sedentary overweight/obese men to training may be different to that of young active men reported in previous studies (1,2). It should be noted that considerably greater work and time were spent completing the TER compared to SIT, but neither group elicited notable improvements. Further research is necessary to extend the training period to see if TER and SIT produce beneficial effects in sedentary, overweight/obese men. References 1) Gibala MJ et al. #### EFFECT OF HIGH- VERSUS MODERATE-INTENSITY INTERVAL TRAINING ON AEROBIC FITNESS IN SOCCER PLAYERS

IMPELLIZZERI, F.M., CASTAGNA, C., COUTTS, A.J., SCHENA, F., SANTOS, T.M.

UNIVERSITY OF VERONA

EFFECT OF HIGH- VERSUS MODERATE-INTENSITY INTERVAL TRAINING ON AEROBIC FITNESS IN SOCCER PLAYERS Impellizzeri FM1, Castagna C2, Coutts AJ3, Schena F1, Santos TM4 1: CeRISM, University of Verona (Rovereto, Italy), 2: University of Tor Vergata (Rome, Italy), 3: UTS

(Sydney, Australia); 4: Universidade Gama Filho (Rio de Janeiro, Brasil) Introduction Interval training performed at intensities from 90 to 95% of maximal heart rate (HRmax) has been shown to improve maximal aerobic power (VO2max) and soccer-specific endurance [1]. No studies have examined whether interval training performed at lower intensity induces similar effects. The aim of the study was to compare the effects of moderate and high-intensity interval training on aerobic fitness in junior soccer players. Additional aims were to examine whether an increase of interval training intensity from moderate to high-intensity determined additional improvements, and whether one session a week of high-intensity training is enough for maintaining the aerobic fitness. Methods Twenty-eight male players from two teams were randomized during the competitive season into two groups: high-intensity (HIGH, 90-95% of HRmax; final n=11) and moderate-intensity (MOD, 80-85% of HRmax; final n=10) interval training. Twenty-one players completed the study: age 17 (SD 1) years old, height 176 (5) cm, and weight 71 (8) kg. We used two interrupted-time series (ITS) designs nested in a randomized parallel-group trial (RPT). Training lasted 6 weeks for the RPT and additional 6 weeks for each arm (MOD and HIGH) for the ITS. In the RPT both groups trained 6 weeks twice a week. After this period MOD increased the intensity to 90-95% of HRmax for 6 weeks, while HIGH decreased the training frequency to one session a week. Before (pre), after the RPT (mid) and after the ITS (post) players performed the Yo-Yo Intermittent Recovery Test and VO2max test. Results No effect of group was found for VO2max ( $P=0.519$ ). The group  $\times$  time interaction was significant for the YYIRT ( $P=0.002$ ). The MOD group increased the YYIRT by 4.1% (90%CI -1.5 to 10%) from pre to mid, and 8.5% (5.7 to 11.6%) from mid to post (compare to pre: 13%, 6.2 to 20.3%). The HIGH group increased the YYIRT by 15.5% (8.5 to 22.8%) from pre to mid, and -0.6% (-3.3 to 2.3%) from mid to post (compare to pre: 14.8%, 8.0 to 22.1%). No changes were found for VO2max. Discussion This study showed that during the competitive season high-intensity interval training induced greater improvements in YYIRT than the same exercise modality completed at moderate intensity. The increase of exercise intensity to about 90% of HRmax induced in the MOD group improvements comparable to HIGH. Furthermore, training once a week using high-intensity interval training seems to be sufficient to maintain the specific-endurance level. References 1) Iaia FM, Rampinini E, Bangsbo J. ### ACUTE PHASE RESPONSE TO MODERATE AND HIGH INTENSITY AEROBIC EXERCISE IN SEDENTARY YOUNG MALES

AZADPOUR, N.1, TARTIBIAN, B.2, KOSAR, S.N.1

1: HACETTEPE UNIVERSITY (ANKARA, TURKEY), 2: UU (URMIEH, IRAN)

Introduction Exercise induced local inflammatory response is accompanied by a systemic response known as the acute phase response (APR) (1). Inflammatory response is essential and promotes tissue healing. However, improper regulation of inflammation can lead to excess tissue damage. IL-6 is the main cytokine involved in the induction of APR, which includes synthesis of certain proteins in the liver such as c-reactive proteins (CRP). To date a few studies compared the acute exercise-induced IL-6 and CRP responses to moderate and high intensity aerobic exercise. Therefore, the aim of this study was to compare APR to one bout of aerobic exercise of moderate and high intensities in sedentary young males. Furthermore, we aimed to evaluate the impact of IL-6 released during exercise on CRP generation. Methods Eighteen young sedentary volunteers (age range 20-26 years, BMI: <25) were assigned to either moderate (ME, n: 8, 60% VO2max) or high (HE, n: 10, 75% VO2max) intensity exercise groups. Each group ran on the treadmill for 30 minutes at the respective exercise intensities. Blood samples were collected before, immediately after and 2 h after the exercise session to determine IL-6 and CRP levels. IL-6 and CRP were measured by nephelometry and ELISA, respectively. The data analyzed by paired t-test and ANOVA with repeated measures (General Linear Model). Results A single bout of both moderate and high intensity exercise induced significant increases in serum CRP and IL-6 levels ( $p<0.05$ ), however, no significant difference was observed between experimental groups (time  $\times$  group effects) ( $p>0.05$ ). There was no significant correlation between serum levels of IL-6 and CRP either at immediately or 2 h after exercise ( $p>0.05$ ). Discussion Findings of this study demonstrated that a single bout of both moderate and high intensity aerobic exercise increased serum IL-6 and CRP concentrations in untrained males. Exercise intensity didn't seem to affect the magnitude of the increase in either IL-6 or CRP within the limits of this study. Moreover, there was no association between IL-6 and CRP at any observation consistently with the literature (2). Therefore, it seems that there are other factors stimulating CRP synthesis in response to acute exercise other than IL-6. References 1. Gruys E, Toussaint MJM, Niewold TA, Koopmans SJ. ### CHANGES IN PHOSPHOCREATINE CONCENTRATION OF SKELETAL MUSCLE DURING INTENSIVE INTERMITTENT EXERCISE IN CHILDREN AND ADULTS

RUNKEL, B.1, KAPPENSTEIN, J.1, FERRAUTI, A.1, MÜLLER, K.2, ZANGE, J.2

1: RUHR-UNIVERSITY BOCHUM, DEPARTMENT OF COACHING SCIENCE (BOCHUM, GERMANY), 2: GERMAN AEROSPACE CENTER DLR, INSTITUTE OF AEROSPACE MEDICINE (COLOGNE, GERMANY)

Introduction It was shown that children possess a higher resistance to fatigue and a quicker recovery during high-intensive intermittent exercise compared to adults, which is mainly explained by lower blood lactate concentrations and a more stable blood pH (Falk & Dotan, 2006; Ratel et al., 2006). The aim of the present study was to investigate if this can also be explained by the amount and speed of phosphocreatine (PCr) breakdown and resynthesis during and after intensive short-term anaerobic interval work. Methods 16 untrained children (C; 8 girls, 8 boys:  $9.2\pm0.3$  yrs;  $139\pm6$  cm;  $35.8\pm7.7$  kg body mass;  $16.6\pm2.8$  kg muscle mass) and 16 untrained adults (A; 8 women, 8 men:  $26.1\pm0.3$  yrs,  $175\pm8$  cm,  $69.1\pm9.4$  kg body mass,  $40.1\pm8.2$  kg muscle mass) participated in the study. All subjects completed an intermittent protocol of dynamic plantar flexion followed by 10 min of passive recovery. The protocol consisted of 10 bouts of 30s exercise (24 concentric and eccentric movements) intermitted by 20s recovery. The individual load corresponded to the 28 repetition maximum. We recorded the absolute and relative changes of PCr during exercise and during post exercise recovery by means of non invasive <sup>31</sup>P-magnetic resonance spectroscopy as well as the mean force production. Results The results (mean $\pm$ SD) were calculated using a multi factor ANOVA (main factors were age, sex and measurement time). No significant differences between the age groups were found for the initial PCr concentrations. Average relative PCr break down during each exercise period was significantly lower ( $p<0.05$ ) in C ( $-71.4\pm5.4\%$ ) compared to A ( $-85.8\pm4.9\%$ ). Time constant to reach 63% of initial PCr during post exercise recovery was significantly shorter in children (C:  $47\pm31$ s, A:  $74\pm33$ s,  $p<0.05$ ). Force production relative to maximum values did not differ significantly between C and A. Discussion The results give further explanations for the intermittent exercise performance of children. Our data suggest that children require more aerobic and less anaerobic pathways for ATP production than adults. The lower PCr-breakdown during exercise and the accelerated PCr-resynthesis during recovery point to a better oxygen transport or utilization in the working muscles. This can possibly be attributed to an improved muscle flow after maximum contraction and a greater oxidative mitochondria capacity related to skeletal muscle mass. Coaches should be encouraged to include more short term intensive intermittent work in children's work out. References Falk B, Dotan R. (2006). *Exerc Sport Sci Rev*, 34, 107-12. ## THE ADDITION OF STRENGTH TRAINING TO HIGH-INTENSITY INTERVAL EXERCISE TRAINING IN CHRONIC HEART FAILURE PATIENTS

KARATZANOS, E.1, DIMOPOULOS, S.1, TASOULIS, A.1, AGAPITOU, V.1, ZERVA, E.1, NTALIANIS, A.2, TERROVITIS, I.2, NANAS, S.1  
(1) CARDIOPULMONARY EXERCISE TESTING AND REHABILITATION LABORATORY, (2) 3RD CARDIOLOGY DEPARTMENT

**INTRODUCTION:** Aerobic exercise training is an important means of cardiopulmonary rehabilitation in chronic heart failure (CHF) patients. The effects of strength training inclusion in an aerobic regime, especially a high-intensity one, have not been thoroughly studied. The aim of this study was to investigate the effects of two different regimes (high-intensity interval vs. combined) on exercise capacity in CHF. **METHOD:** Forty four CHF patients, 36 males / 8 females [(M±S) age: 53.6±11.5 yrs, VO<sub>2</sub>peak: 15.9±4.8 ml/kg/min] participated in an exercise training program for 12 weeks, 3 times/week. Participants were randomly assigned to either aerobic (AER, n=20) or combined regime (COM, n=24), which included aerobic and strength training. Aerobic exercise was performed in interval type (30 sec exercise – 60 sec rest) on cycle ergometers at intensity >100% VO<sub>2</sub>peak. Strength training involved exercises for various muscle groups, including the quadriceps. Both regimes were of the same duration. At the beginning and the end of the program, participants performed a maximum symptom-limited test to exhaustion to assess oxygen uptake at the peak (VO<sub>2</sub>peak) and the anaerobic threshold (VO<sub>2</sub>AT), the corresponding power outputs (Wpeak and WAT), the linear VO<sub>2</sub> slope at the first minute of the recovery phase (VO<sub>2</sub>/t slope), and a 2-resistance maximum test (2-RM) for each leg to assess quadriceps strength. **RESULTS:** The whole cohort improved (p<0.05) VO<sub>2</sub>peak (from 15.9±4.8 to 18.3±5.5 ml/kg/min), VO<sub>2</sub>AT (from 10.3±2.8 to 11.4±2.9 ml/kg/min), Wpeak (from 101±38 to 119±42 watt), WAT (from 58±23 to 70±25 watt), the VO<sub>2</sub>/t slope (from -0.48±0.25 to -0.60±0.28 ml/kg/min<sup>2</sup>) and the 2-RM sum of the two legs (from 35.6±13.1 to 44.0±17.5 kg). In relation to between-group comparison, COM improved more than AER (p<0.05) in VO<sub>2</sub>peak (AER: from 16.4±4.2 to 17.8±4.7 ml/kg/min, COM: from 15.5±5.3 to 18.7±6.1 ml/kg/min), the VO<sub>2</sub>/t slope (AER: from -0.49±0.25 to -0.56±0.25 ml/kg/min<sup>2</sup>, COM: from -0.46±0.25 to -0.64±0.31 ml/kg/min<sup>2</sup>), and 2-RM sum (AER: from 35.9±12.6 to 39.2±13.2 kg, COM: from 35.3±13.9 to 48.0±19.7 kg). No between-group differences were found (p>0.05) on VO<sub>2</sub>AT (AER: from 10.4±2.5 to 11.2±2.8 ml/kg/min, COM: from 10.2±3.1 to 11.5±3.0 ml/kg/min), WAT (AER: from 60±18 to 69±19 watt, COM: from 56±28 to 71±30 watt) and Wpeak (AER: from 104±29 to 118±30 watt, COM: from 99±44 to 120±51 watt). **DISCUSSION:** A combined rehabilitation program of high-intensity aerobic interval and strength training, in comparison to an aerobic interval regime, induced at least similar improvements on aerobic parameters of functional and predictive value and greater enhancement of the maximum strength in CHF patients. Strength training is safe, well-tolerated, and can amplify the benefits of the CHF exercise training rehabilitation programs.

### OP-PM28 Stress Damage Inflammation 1

## THE INFLUENCE OF BODY TEMPERATURE ON THE OXIDATIVE STATUS OF THE PLASMA IN LONG DISTANCE RUNNERS AND UNTRAINED MEN

SZYGULA, Z.1, PILCH, W.1, TORII, M.2

1: UNIVERSITY SCHOOL OF PHYSICAL EDUCATION, (KRAKOW, POLAND); 2: KYUSHU INSTITUTE OF TECHNOLOGY, (KITAKYUSHU, JAPAN)

**Introduction** Prooxidant-antioxidant status of the organism depends on different factors such as physical effort or elevation of body temperature. The aim of this study was to evaluate changes in plasma oxidative status under exogenic heat in sauna and combined exogenic and endogenic heat during prolonged exercise in elevated environment temperature in untrained and trained men. **Methods** Ten untrained non-smoking, healthy men (20-22 yrs; 44.46±8.98 ml kg<sup>-1</sup>min<sup>-1</sup>) - UT group and ten long distance runners (20-23 yrs old; VO<sub>2</sub>max 60.53±13.5ml kg<sup>-1</sup>min<sup>-1</sup>) - T group participated in this study. They had not been accustomed to sauna before. There were 2 tests during the experiment. In the 1st one the subjects had been pedaling on a cycloergometer with intensity of 53±2%VO<sub>2</sub>max in the climatic chamber (temp. 33±1°C; RH 70%) until the rectal temperature (Tre) increased by 1.2°C. The 2nd test consisted of passive heating in a Finnish sauna (96±2°C at face-level; RH 5-16%). The subjects stayed in the sauna for 15 min and were subsequently cooled down for 2 minutes under the shower (temp. 20°C). Warming and cooling were repeated until Tre increased by 1.2°C. Body mass (BM), heart rate (HR) and Tre were measured. Venous blood was taken before and 3 min after sauna exposure. Hematocrit and hemoglobin concentration were measured in full blood. Total protein concentration, lactate concentration (La), lipid peroxidation concentration (PerOx) and antioxidant plasma concentration (AntiOx) were measured in the plasma samples. **Results** The resting AntiOx was higher by 10-25% (p<0.05) in T compare to UT subjects, whereas PerOx was higher by 40-53% (p<0.05) in UT subjects before both tests. After exercise test AntiOx decreased by 24% and PerOx increased by 62% in UT subjects (p<0.05), whereas 21% decrease in AntiOx and 90% increase in PerOx were observed in T subjects (p<0.05). After sauna exposure 65% decrease in AntiOx and 37% increase in PerOx were observed in UT subjects (p<0.05), whereas AntiOx decreased by 21% and PerOx increased by 56% in T subjects (p<0.05). The differences in changes between T and UT were statistically significant in both tests. **Discussion** Physical training leads to improvement in prooxidant-antioxidant status of the organism. Changes in the level of the indicators of oxidative stress observed after exercise test were greater among athletes comparing to untrained subjects, which may be explained by longer work periods and a faster pace of glycolysis, as is indicated by higher concentrations of lactate observed following the exertion. Physical exercise in the elevated temperature of the environment caused greater changes of the indicators of oxidative stress (PerOx) than heating in sauna.

## LOW-INTENSITY ECCENTRIC CONTRACTIONS ATTENUATE MUSCLE DAMAGE INDUCED BY MAXIMAL ECCENTRIC CONTRACTIONS FOR 2 WEEKS

CHEN, T.C.1, CHEN, H.L.1, NOSAKA, K.2

1: NATIONAL CHIAIYI UNIVERSITY, TAIWAN, 2: EDITH COWAN UNIVERSITY, AUSTRALIA

**Introduction** It has been reported that eccentric exercise with a light dumbbell that does not change any muscle damage markers provides some protection against a subsequent bout of a higher intensity eccentric exercise with a heavier dumbbell performed 2 days later (1). It appears that the duration of the protection remains is dependent on the magnitude of the initial muscle damage; however, it is unknown how long the protective effect lasts when the initial eccentric exercise bout induces little or no muscle damage. This study investigated how long the protective effect induced by a low-intensity eccentric exercise against maximal eccentric exercise would last.

**Methods** Sixty-five untrained men ( $21.3 \pm 1.6$  y) were assigned ( $n=13$  per group) to four repeated bout groups and one control group. The four repeated bout groups performed 5 sets of 6 submaximal eccentric contractions of the elbow flexors using a dumbbell set at 10% of maximal isometric strength at  $90^\circ$  (10%-ECC) for the first bout followed 2 (2d), 7 (1w), 14 (2w) or 21 days (3w) by 5 sets of 6 isokinetic ( $30^\circ.s^{-1}$ ) maximal eccentric contractions (Max-ECC) using non-dominant arm. The control group performed Max-ECC only. The dependent variables included maximal voluntary isometric and isokinetic ( $30^\circ.s^{-1}$ ) concentric strength, range of motion, upper arm circumference, muscle soreness, plasma creatine kinase activity and myoglobin concentration, and echo-intensity of the B-mode ultrasound images. Changes in the variables following 10%-ECC were analysed by a one-way repeated measures ANOVA, and the changes following Max-ECC were compared among the groups by a two-way repeated measures ANOVA. Results The 10%-ECC did not change any of the dependent variables. The changes in all dependent variables following Max-ECC were significantly ( $P<0.05$ ) smaller for the 2d, 1w and 2w groups compared with control groups, without significant differences between the 2d and 1w groups. The 2w group showed significantly ( $P<0.05$ ) greater changes in all variables compared with the 2d and 1w groups. Changes in the variables were similar between the 3w and control groups, except for muscle soreness that showed significantly ( $P<0.05$ ) smaller changes for the 3w than the control group. Discussion These results confirmed that non-damaging eccentric exercise conferred protective effect against maximal eccentric exercise, supporting the previous study finding (1) and showed that the protective effect lasted for 2 weeks, but the protective effect was attenuated between 1 and 2 weeks. A light eccentric exercise should be performed within 2 weeks prior to a higher intensity eccentric exercise to attenuate muscle damage. References 1) Lavender AP, Nosaka K. (2008). J Sci Med Sport, 11, 291–98.

### **ASSOCIATION OF INFLAMMATORY FACTORS , OXIDATIVE STRESS AND CELL INJURY INDICES AFTER STRENUOUS TRAINING PERIODS AND VITAMIN-MINERAL SUPPLEMENTATION**

AZIZI, M., RAZMJOU, S., RAJABI, H., AHMADI, P.

ISLAMIC KARAJ AZAD UNIVERSITY

This study is aimed to investigate the association of inflammatory factors (IL6, TNF $\alpha$ ), oxidative stress (MDA) and cell injury indices after strenuous training periods and Vitamin-mineral supplementation in female elite swimmers. Materials and Methods: Twenty-four elite female swimmers volunteered to participate in this study and were randomly divided into two groups, the experimental (Vitamin-mineral supplemented) and the control (Placebo). Both groups were in a monthly swimming programs, 3 times a week, for a total of 4 weeks and swimming, almost 3.5 to 4 km/d. Blood sampling was done before and after the training period to assess inflammatory cytokines such as IL-6 and TNF- $\alpha$ , and also MDA and muscle injury indices, such as aspartat aminotransferase (AST), creatine kinase (CK), lactate dehydrogenase, and myoglobin. 100 m crawl records were measured at the beginning and the end of the training period. Results: Results showed that inflammatory cytokines decreased significantly in the vitamin-mineral supplemented group, and MDA decreased, though not significantly, in this group. There was no significant change between the groups. No significant change was observed in swimming performance in either groups. Some of the muscle injury indices, namely, CK and AST, decreased significantly in the vitamin-mineral-supplemented group ( $p=0.011$  and  $0.04$ , respectively). Inter-group comparisons showed a difference only with regard to CK ( $p=0.021$ ). Conclusion: In conclusion, ROS was found to affect exercise-induced cytokine production, in which Vitamin-mineral supplementation was found to play an effective role

### **MULTI-ANALYTICAL MEASUREMENT OF HORMONES AND CYTOKINES WITH EVIDENCE BIOCHIP ARRAYS**

HUXLEY, A., KELLY, F.M., RODRIGUEZ, M.L., MCCONNELL, R.I., FITZGERALD, S.P.

RANDEX LABORATORIES LTD

**MULTI-ANALYTICAL MEASUREMENT OF HORMONES AND CYTOKINES WITH EVIDENCE BIOCHIP ARRAYS** Huxley, A., Kelly, F.M., Rodriguez, M.L., McConnell, R.I., Fitzgerald, S.P. Randox Laboratories Ltd., 55 Diamond Road, Crumlin, Co Antrim BT29 4QY, Northern Ireland, UK. Introduction Using miniaturized assay procedures, Evidence biochip array technology enables the simultaneous determination of multiple analytes from a single sample with the reduction of sample/reagent consumption and better cost-effectiveness of the tests. Variations in the levels of hormones such as cortisol, dehydroepiandrosterone-sulphate (DHEAs),  $17\alpha$ -hydroxyprogesterone ( $17\alpha$ -OHprog) and leptin in response to physical exercise have been reported. The intensity and duration of the exercise is also related to the plasma levels of cytokines that influence leukocyte functions. The multi-analytical measurement of these molecules generates a quantitative profile, providing more information than single-analyte determinations, which is relevant in studies of complex interactive networks. We report the application of biochip arrays to the multiplex measurement of hormones and cytokines. Methods Simultaneous chemiluminescent immunoassays are employed for analyte detection and the microarrays of capture ligands define the discrete test areas for each of the analytes in the biochip (9mm x 9mm). The semi-automated analyser Evidence Investigator was used. The system automatically processes, reports and archives the generated data. Results The endocrine biochip array allows simultaneous quantitative determination of cortisol, DHEAs,  $17\alpha$ -OHprog and leptin with the following sensitivity values: 5.88ng/ml (cortisol, calibration range 0-800ng/ml), 0.003 $\mu$ g/ml (DHEAs, calibration range 0-10 $\mu$ g/ml), 0.1ng/ml ( $17\alpha$ -OHprog, calibration range 0-20ng/ml) and 0.64ng/ml (leptin, calibration range 0-100ng/ml). Twenty-two soluble cytokines and five cytokine related markers are determined using different biochip arrays with sensitivity values ranging from 0.74pg/ml (IL-15) to 3.03ng/ml (MMP-9). For all the assays the intra-assay and inter-assay precision, expressed as %CV, were typically <15%. Conclusion The data indicate applicability of biochip array technology to the multiplex determination of a broad range of biomarkers. This technology enables the generation of quantitative patient profiles and represents a useful tool for application in clinical research settings.

#### **VISUALISATION OF KINEMATIC PARAMETERS IN GAIT TRAINING: USING THE EXAMPLE OF TOTAL HIP REPLACEMENT**

HAMACHER, D., SCHEGA, L.

OTTO-VON-GUERICKE-UNIVERSITY MAGDEBURG

Introduction Augmented Reality (AR) is mainly used in industrial scenarios. However, the efficiency of AR-based interventions to optimize established rehabilitation processes still remains unknown. Hence, the purpose of the present study is the evaluation of AR vs. conven-

tional therapeutic instructions during gait training in patients with total hip replacement (THR). Methods A total of 21 patients (female,  $58 \pm 4.3$  years) with THR have been randomly assigned either to an intervention group (IG,  $n = 11$ ) or a control group (CG,  $n = 10$ ). Additional to the post-hospital curative treatment all patients passed a standardized gait training (20 min / day). Corrections of gait patterns were given by either verbal therapeutic instructions (CG) or with help of an AR-based real-time visualisation (IG). In order to identify differences between the intervention strategies, a pre-test, follow up test and post-test were performed. Based on clinical gait analysis the assessment of kinematic values (Moven, Xsens) and neuro-physiological parameters (surface electromyography, SEMG, 16-channel Noraxon) is conducted. A reference group (RG) of 26 subjects without any motor and functional impairments (female,  $59 \pm 11$  years) was utilized to capture kinematic reference values (Moven). These data served as reference values for visualization (IG) and in comparison with the IG and CG. Results Initial results show no differences in SEMG data of the IG vs. CG. In comparison of CG vs. RG significant differences in gait velocity ( $p = .001$ ) were analysed in the post test. In contrast, for IG vs. RG we could not find any differences. Furthermore, significant differences were detected in CG post-test vs. RG post-test in the average inclination ( $p = .027$ ) and range of motion ( $p = .000$ ) of the pelvis in the frontal plane. Discussion If the AR-based intervention treatment is used, equivalent results seem to be achievable compared to conventional therapeutic instructions. Particularly due to further reduction of the technical complexity and temporal outlay of this technology, the presented approach appears to be a promising and effective tool to optimize rehabilitation processes, such as in rehabilitation of individuals with total hip replacement.

## EFFICACY OF RICE THERAPY IN TREATING ECCENTRIC EXERCISE-INDUCED MUSCLE DAMAGE

SEMPLE, S.1,2, CALDEIRA, M.2, SIBANDA, E.2, NEVELING, N.2, SMITH, L.2

(1) UNIVERSITY OF ZULULAND; (2) TSHWANE UNIVERSITY OF TECHNOLOGY

Introduction RICE therapy (rest, ice, compression, elevation) is a universally accepted clinical practice for immediate treatment of any soft tissue injury including sprains, strains and contusions. Whilst individual components of the RICE principle have been tested and proven to be effective, no single trial has been conducted to prove the efficacy of this treatment modality in its entirety. In addition it is not known if participants receiving RICE therapy would demonstrate the typical adaptation following muscle damage i.e. the repeated bout effect. Methods Nineteen healthy, active but untrained males were recruited for the study. The participants performed 12 sets of elbow extensions (eccentrically-biased) at a pre-determined repetition maximum (bout 1). They were then randomly assigned to the RICE treatment or control group (CG). Indirect markers of muscle damage were recorded at 3, 6, 9, 12, 24, 48, 72, 96 and 120h post exercise. The same procedure was followed 4 weeks later (bout 2). Results For creatine kinase there was a significant group effect ( $p = 0.002$ ). Values for RICE for both bouts of exercise combined ( $2119 \pm 514$  IU/L) were 53% lower than for both bouts of eccentrics performed by the CG ( $4019 \pm 639$  IU/L). Isometric strength (expressed as % of baseline) in the CG between bout 1 ( $76 \pm 4\%$ ) and bout 2 ( $93 \pm 3\%$ ) was significantly different, while surprisingly, there was no significant difference for RICE between bout 1 ( $81 \pm 3\%$ ) and bout 2 ( $85 \pm 3\%$ ). For the first 12h post exercise the RICE group experienced greater ( $p = 0.002$ ) DOMS however during the subsequent 12h periods (up until 120h post) the CG experienced greater DOMS ( $p = 0.009$ ). Neutrophils and monocytes were 3-15% higher ( $p < 0.05$ ) in the CG following the exercise bouts. Significant bout effects were observed for all markers indicating the manifestation of the repeated bout effect. Discussion The primary objective of this study was to determine if RICE therapy is effective in reducing indirect markers of muscle damage following a bout of strenuous unaccustomed eccentric exercise. A second aim of the study was to determine if the repeated bout phenomenon would manifest in participants that had received RICE therapy, in other words would RICE therapy 'interfere' with normal adaptive healing processes. RICE therapy improved recovery from a bout of strenuous eccentric exercise and failed to negatively impact on a subsequent bout performed 4 weeks later. The latter finding may only be of practical significance for recreational athletes or those training sporadically. The results may give support to the application of RICE therapy following normal 'uneventful' strenuous training that is likely to induce DOMS. References Bleakley C, McDonough S, MacAuley D. Am J Sports Med. 2004;32 (1):251-261. Jarvinen TAH, Jarvinen TLN, Kaariainen M, Kalimo H, Jarvinen M. Am J Sports Med. 2005;33 (5):745-764.

## THE EFFECTIVENESS OF AN INJURY PREVENTION PROGRAMME ON PHYSICAL ACTIVITY INJURY INCIDENCE IN PRIMARY SCHOOL CHILDREN

COLLARD, D.

MULIER INSTITUTE

Collard D. 1, Chinapaw M. 2, Verhagen E. 2, van Mechelen W. 2 1: Mulier institute ('s-Hertogenbosch, The Netherlands), 2: EMGO Institute for Health and Care Research, VU University Medical Center (Amsterdam, The Netherlands). Introduction The health benefits of regular sport activities in children are widely known. Participation in sport activities, however, also increases the risk of adverse effects, such as injuries. Although most physical activity injuries in children are not life-threatening, they may coincide disability, school absence, and loss of enthusiasm for participating in sports. Given these consequences of injuries, prevention of injuries in children is an important public health issue. Methods The Injury Prevention Lessons Affecting Youth (iPlay) intervention programme was developed according to the intervention mapping protocol. The 8-month intervention programme focused on both children and parents and included newsletters, posters displayed in the classroom and an exercise programme to improve physical fitness of children. The iPlay-study was designed as a cluster randomised controlled trial. Forty schools (about 2200 children) were willing to participate in the study. Before baseline measurements a randomisation was performed. The intervention group received the iPlay-programme during 1 school year, whereas the control group followed the regular curriculum. To evaluate the effect of the iPlay-intervention on the number of injuries per 1000 hours of sports participation all children completed a questionnaire that collected information on demographic variables and frequency and duration of sports club and leisure time activities (exposure time). In addition, all injuries as a result of physical activities were registered throughout the schoolyear. Results The analyses showed a positive intervention effect on total, sport club and leisure time injuries, although these effects were not significant due to lack of statistical power. Remarkably, the data showed that children who were less physically active had more benefit from the iPlay-programme. In this group the iPlay-programme reduced the total and leisure time injury incidence density with approximately 50%. Sport club injury incidence density in this group was significantly reduced. Furthermore, children in the intervention group reported less often sporting time loss as a result of an injury than those in the control group. Discussion In this study, individual randomisation was no option due to the school-based nature of the iPlay-programme. When calculating the sample size for a cluster randomised controlled trial it is essential to address clustering. Often studies do not adequately account for clustering effects in design and analysis. Our results showed that cluster effect in this study was much larger than expected, thereby decreasing statistical power.

**A PROSPECTIVE COHORT STUDY ON MINOR BICYCLE ACCIDENTS IN COMMUTER CYCLISTS IN BELGIUM**

DE GEUS, B.

VRIJE UNIVERSITEIT BRUSSEL

**A PROSPECTIVE COHORT STUDY ON MINOR BICYCLE ACCIDENTS IN COMMUTER CYCLISTS IN BELGIUM** Bas DE GEUS<sup>1</sup>, Grégory VANDEN-BULCKE<sup>2</sup>, Bart DEGRAEUWE<sup>3</sup>, Luc INT PANIS<sup>3,4</sup>, Elke CUMPS<sup>1</sup>, Joris AERTSENS<sup>3</sup>, Isabelle THOMAS<sup>2</sup>, Rudi TORFS<sup>3</sup>, Romain MEEUSEN<sup>1</sup> 1 Vrije Universiteit Brussel; 2 Université catholique de Louvain; 3 Flemish Institute for Technological Research; 4 University of Hasselt INTRODUCTION Bicycle injury statistics from police, hospital and insurance statistics are well described, but predominantly include major or fatal injuries. In Belgium, it is estimated that 15 to 30% of the cycling accidents are officially reported. Studies showed large differences in bicycle use and incidence (major accidents) between the three institutional regions which reflects similar situations in other countries. To get insight in minor bicycle accidents and to overcome underreporting, the SHAPES project conducted a prospective cohort study on bicycle accidents using an online registration system. Bicycle accident and exposure data were prospectively collected in order to calculate injury incidence density (ID) of minor bicycle accidents. METHODS Participants who are included in the data analysis live in Belgium, are 18-65 years and cycled to work >2 times/wk. Inclusion criteria for accident registration were: bicycle accident occurred during cycling for transport; acute injury; accident resulting in corporal damage. Week books were prospectively filled out every week for 1 year, including travel frequency, distance and time spent cycling. If an accident occurred, a detailed questionnaire was filled out. RESULTS One thousand eighty-seven adult cyclists were included. Over the 1 year follow-up period, 20107 weeks were covered. 62 participants were involved in 70 minor (ICISS ≤0.941) bicycle accidents, resulting in an overall ID of 0.287 (95% CI 0.216-0.358) per 1000 trips, 0.794 (95% CI 0.596-0.991) per 1000 hours and 0.042 (95% CI 0.032-0.052) per 1000 kilometres of exposure. The incidence of accidents differed between the regions and between gender, but when exposure is taken into account these differences were not significant. Injuries were mainly caused by 'slipping' (35.7%) and 'direct contact with a car' (18.6%). Accidents caused abrasions (41.6%) and bruises (27.0%) on the lower (45.3%) and upper extremity (41.3%). In 7.1%, 10.0% and 30% of the cases the police, hospital emergency department or insurance company was involved respectively. 44.3% of the participants indicated that they could have avoided the accident. DISCUSSION & CONCLUSION Keeping cycling surfaces clean, avoid direct contact with cars and cyclists paying attention are measures to decrease the injury incidence. Underreporting of minor bicycle accidents in Belgium has been confirmed. Incidence differs between regions and gender, but when exposure is taken into account (ID) these differences are not significant anymore. If exposure is not taken into account, no statement can be made about whether or not safety measures are effective.

**NINE MONTHS OF PILATES TRAINING ARE EFFECTIVE IN ENHANCING THE FITNESS LEVEL OF ADULT WOMEN**

CORTIS, C., CAPRANICA, L., SANTOBUONO, E., DI CRISTOFARO, C., PIACENTINI, M.F.

UNIVERSITY OF ROME FORO ITALICO

**NINE MONTHS OF PILATES TRAINING ARE EFFECTIVE IN ENHANCING THE FITNESS LEVEL OF ADULT WOMEN** Cortis C.1,2, Capranica L.1, Santobuono E.3, Di Cristofaro C.3, Piacentini M.F.1 1: Department of Human Movement and Sport Science, University of Foro Italico (Rome, Italy), 2: Department of Sport Science and Health, University of Cassino, (Cassino, Italy), 3: University of Molise (Campobasso, Italy) Introduction Pilates training focused on the improvement of flexibility, strength, and posture (Caldwell et al., 2009; Kloubec, 2010). Although this activity is very popular among women, there is a lack of longitudinal studies. Thus, the aim of this study was to evaluate the effects of a 9-month Pilates program on selected fitness components in adult women. Methods Twenty-six women (36.8 ± 9.6 years) participated in a Pilates program (2 sessions weekly). Before (pre) and after (post) the 9-month training period trunk flexibility (sit and reach-SR), muscular endurance (knee push up-KPU and curl up-CU) and cardio respiratory fitness-CRF (Rockport walking test) according to the ACSM's guidelines for exercise testing (ACSM, 2006) were assessed. To verify whether age acts as a confounding factor, participants were divided into 3 age categories (≤30 yrs, n=9; 31-40 yrs, n=8; >40 yrs, n=9). A 3 (age categories) x 2 (experimental sessions) ANOVA for repeated measures was applied to verify differences (p<0.05) before and after the training period. Results Independently from age, at the end of the program participants significantly (p<0.001) improved SR (10.3 ± 6.7 cm), CU (29.9 ± 13.1) and CRF (13.6 ± 2.1 min) performances with respect to basal values (SR: 5.9 ± 7.9 cm; CU: 21.6 ± 11.2; CRF: 17.4 ± 2.1 min). KPU showed significantly (p<0.001) higher pre values in the 31-40 yrs group (15.6 ± 8.5) compared to the ≤30 yrs (9.3 ± 2.5) and the >40 yrs (8.6 ± 5.8). The post values were different only between 31-40 yrs (17.4 ± 7.6) and >40 yrs (11.8 ± 3.5) group. Discussion Although CRF improvements from pre to post evaluations were similar (21%) among age categories, a different trend emerged for SR (range: 103-209%), CU (range: 44-58%) and KPU (range: 31-86%), with the >40 yrs category always showing the highest improvements, probably due to the pre higher overall fitness of the other age categories. However, the present results show that a 9-month Pilates program enhances flexibility, muscular endurance and also if in a lower extent, cardio respiratory fitness performances regardless of age. **STANDARD PHYSIOTHERAPY AFTER ELECTIVE TOTAL HIP REPLACEMENT IN THE UK: AN OBSERVATIONAL STUDY OF PRACTICE.**

OKORO, T., RAMAVATH, A., JENKINSON, J., HOWARTH, J., LEMMEY, A., MADDISON, P., ANDREW, G.

BANGOR UNIVERSITY

**BACKGROUND** Total hip replacement (THR) has revolutionised the care of patients with end stage joint disease, leading to pain relief, and substantial improvement in quality of life (1). However there is a persistence of impaired function, even in the absence of pain (2). This may be due to the lack of a standardised approach to rehabilitation (3) and/or the failure to incorporate progressive resistance training (PRT), an exercise modality proven to improve muscle strength and function following THR (3). This study aimed to investigate 'standard' rehabilitation care in the UK after THR. **METHODOLOGY** After Local Research Ethics approval, the development of questionnaire items about physiotherapy practice was guided by a focus group interview with a small number of physiotherapists (n = 4; minimum 5 years post-qualification) who regularly treated patients undergoing THR. 25 items were developed to reflect the exercises prescribed in the pre-operative and post-operative phases. These questions were then sent via email to physiotherapists identified from hospitals on the National Joint Registry and the Chartered Society of Physiotherapists website. **RESULTS** On analysis of 67 responses, the most important muscle group to target in the pre and postoperative phase were reported to be the hip abductors (57%), followed by the quadriceps (19%), and other muscles (24%). No consensus existed as to which form of exercise was most important in these phases; with weight bearing (42%) and functional (41%) exercises being the most favoured and bed-based/bridging/postural exercises together accounting

for 17% of responses. Despite 76.2% of respondents knowing what PRT entailed, only 34.9% routinely built it into the exercises prescribed. A majority (68.2%) did not refer their patients on for further physiotherapy post-operatively. In the outpatient setting, the prescribed regimens consist of functional exercises (60%), weight bearing exercises (20%) and bed-based/hydrotherapy exercises (20%). CONCLUSIONS Despite the evidence base supporting PRT use in THR rehabilitation, only approximately one-third of physiotherapists surveyed include it in their prescribed programs. Education to facilitate standardisation of post-operative care and increase awareness is needed to help address deficits in function that persist following THR surgery. REFERENCES 1. S. Patil, D. S. #### MATURITY-RELATED DIFFERENCES BY PLAYING POSITION IN U14 YOUTH TEAM HANDBALL PLAYERS

PHILIPPAERTS, R., MATTHYS, S., FRANSEN, J., VAEYENS, R., LENOIR, M.

GHENT UNIVERSITY

**Introduction** Research on anthropometric and physical performance measures in expert adult handball players reveals specific positional demands. During puberty, a shift towards a higher degree of specialized training in youth sports is apparent. However, the shares of diversification and multilateral development versus specialization in this stage are equally large and therefore a complete focus on specialized training during puberty is ill-advised. The purpose of this study was to examine differences in anthropometry and physical performance, accounted for maturation, between field positions in U14 team handball players. **Methods** The sample included 155 male handball players, 13.0 to 13.9 years of age, and mainly playing on one specific position: keeper (n=20), wing (n=68), back (n=49) or pivot (n=18). Morphological and physical performance measures were taken covering most of the physical performance-related characteristics. MANCOVA was used to investigate the positional differences, with age at peak height velocity (APHV as a measure of biological maturation) accounted for. Post hoc tests were executed in case of a significant main effect. All analyses were performed using SPSS 15.0 with the minimal level of significance set at  $p < 0.05$ . **Results** Chronological age was not different between playing positions, whereas APHV revealed a strong significant difference between the positions ( $p < 0.001$ ). The back-positions have a significant earlier maturity offset compared to the wing-position. APHV was a significant covariate ( $p < 0.05$ ) for all anthropometric variables, and in some performance characteristics. Position specific differences were found for height ( $p < 0.05$ ), weight and body fat (both  $p < 0.05$ ). Backs and keepers were in general taller. The lowest weight was observed in wing-players. Back players jumped higher ( $p < 0.05$ ) and further ( $p < 0.01$ ) compared to the other positions, and significant differences were also observed for speed ( $p < 0.05$ ) and agility ( $p < 0.05$ ) in favour of the back players. **Discussion** The result of a maturation-based selection for certain playing positions results in a field position specific specialization as soon as the age of 13. Ideally at this age, players should be encouraged to play a wide variety of field positions instead of just specializing in one. Coaches and training professionals in youth team handball should be aware of the maturity-based selection of young handball players for different playing positions. These differences between players are likely to change throughout puberty and maturity-based selection is therefore not recommended in youth handball.

#### PHYSICAL AND ANTHROPOMETRIC CHARACTERISTICS OF MIDDLE EASTERN YOUNG SOCCER PLAYERS IN COMPARISON TO INTERNATIONAL COUNTERPARTS

SIMPSON, B., BUCHHEIT, M., MENDEZ-VILLANUEVA, A.

ASPIRE

**PHYSICAL AND ANTHROPOMETRIC CHARACTERISTICS OF MIDDLE EASTERN YOUNG SOCCER PLAYERS IN COMPARISON TO INTERNATIONAL COUNTERPARTS** Simpson, B.M., Buchheit, M., and Mendez-Villanueva, A. ASPIRE (Doha, Qatar) **Introduction** The aim of the present study was to compare physical and anthropometric data in highly-trained young soccer players from the Middle East to their international counterparts of Western African and South American origin. **Methods** Seven Middle Eastern soccer players (bone age:  $14.0 \pm 0.0$  y) were compared with five South American matched for bone age ( $14.2 \pm 0.4$  y), playing position and playing standard. Similarly nine other Middle Eastern players ( $17.1 \pm 0.2$  y) were compared with thirteen West African ( $17.2 \pm 0.3$  y) players. All players performed a counter movement jump (CMJ), a 40-m sprint with 10-m splits to estimate maximal sprinting speed (MSS, km/h) and an incremental running test to estimate maximal aerobic speed (MAS). Anaerobic speed reserve (ASR) was calculated as  $MSS - MAS$ . **Results** Compared with South American, Middle Eastern players presented lower neuromuscular abilities (CMJ:  $32.6 \pm 3.1$  vs  $37.6 \pm 2.5$  cm,  $P = 0.01$ ; 10-m sprint:  $1.84 \pm 0.05$  vs  $1.69 \pm 0.04$  s,  $P < 0.01$ ; MSS:  $27.9 \pm 1.3$  vs  $30.4 \pm 1.0$  km/h,  $P < 0.01$ ; ASR:  $11.0 \pm 1.8$  vs  $14.0 \pm 1$  km/h,  $P < 0.01$ ), while MAS was similar ( $16.9 \pm 0.9$  vs  $16.4 \pm 0.7$  km/h,  $P = 0.30$ ). All anthropometric variables were similar (Height:  $165.0 \pm 4.4$  vs  $166.8 \pm 4.2$  cm,  $P = 0.49$ ; Weight:  $48.9 \pm 4.8$  vs  $54.7 \pm 4.7$  kg,  $P = 0.06$ ; sum of six skinfolds:  $44.2 \pm 9.5$  vs  $42.5 \pm 6.6$  mm,  $P = 0.74$ ). When comparing Middle Eastern to Western Africa players, differences were observed in ASR ( $15.3 \pm 1.3$  vs  $13.7 \pm 1.6$ ,  $P = 0.02$ ) and a tendency towards a lower MAS ( $16.2 \pm 1.0$  vs  $17.0 \pm 0.8$  km/h,  $P = 0.06$ , effect size = 0.92). No differences were observed in the remaining physical performances ( $42.2 \pm 5.0$  vs  $39.7 \pm 3$  cm,  $P = 0.16$ ;  $1.71 \pm 0.05$  vs  $1.72 \pm 0.07$  s,  $P = 0.84$ ; MSS:  $31.4 \pm 1.0$  vs  $30.7 \pm 1.1$ ,  $P = 0.12$ ) nor anthropometric variables ( $169.7 \pm 6.8$  vs  $173.0 \pm 6.6$  cm,  $P = 0.27$ ;  $59.0 \pm 4.8$  vs  $61.7 \pm 4.2$  kg,  $P = 0.16$ ;  $47.7 \pm 8.0$  vs  $41.5 \pm 11.4$  mm,  $P = 0.16$ ). **Discussion** Highly-trained Middle Eastern young soccer players had inferior neuromuscular-related performance compared with bone age-matched South American players and inferior MAS compared with Western Africa players, despite similar anthropometric profiles. While these differences could be related to specific genetic profiles, the possible impact of training experience and background on physical qualities could not be controlled for in this study. Further study controlling for training content and background in higher sample sizes are warranted to generalize these findings.

## LONG-TERM SOCCER-SPECIFIC TRAINING ENHANCES THE RATE OF PHYSICAL DEVELOPMENT OF ELITE JUNIOR SOCCER PLAYERS INDEPENDENT OF MATURATION

WRIGLEY, R.1,2, DRUST, B.2, STRATTON, G.2, ATKINSON, G.2, GREGSON, W.2

1BLACKBURN ROVERS FC, UK, 2RESEARCH INSTITUTE FOR SPORT AND EXERCISE SCIENCES, LIVERPOOL JOHN MOORES UNIVERSITY, UK

**Introduction** Elite junior soccer players demonstrate increased physical performance compared to age matched sub-elite players (Vaeyens et al., 2006). However, the degree to which these observations reflect differences in genetic predisposition and growth and maturation relative to training has yet to be fully evaluated. The present study therefore compared changes in physical performance in aged matched elite (E) and sub-elite (SE) junior soccer players across three domestic seasons to determine the relative influence of changes in maturation and training. **Methods** Changes in the physical performance of twenty seven E (U12 (n=9), U14 (n=9), U 16 (n= 9)) and eighteen SE (U12 (n=6), U14 (n=6), U16 (n=6)) soccer players were monitored across three seasons. All E players were part of a Premier League Academy development programme. SE players regularly participated in competitive soccer. Performance tests included countermovement jump, 10m and 20m sprint, repeated sprint (7x30m), agility (505) and intermittent endurance. Changes in maturation status of all players across the three years were estimated using change in the maturity offset (Mirwald et al., 2002). Data were analysed with an age-group x competitive level general linear model with covariates of initial performance and maturation changes. Results Baseline performance across all tests was generally greater in E compared to SE across all age groups ( $P<0.01$ ). A significantly greater improvement in 20m sprint (E,  $0.28\pm0.03$ s; SE,  $0.14\pm0.04$ s;  $P=0.02$ ), agility (E,  $0.18\pm0.02$ s; SE,  $0.06\pm0.02$ s;  $P<0.01$ ), and intermittent endurance (E,  $1031\pm95$ m; SE,  $290\pm110$ m;  $P<0.01$ ) performance was observed in E relative to SE across all ages. This was so even when baseline performance and changes in maturity status were covariate-controlled. Improvements in 10m sprint (E,  $0.14\pm0.02$ s; SE,  $0.09\pm0.02$ s;  $P=0.07$ ) and 30m repeated sprint performance (E,  $0.56\pm0.06$ s; SE,  $0.38\pm0.06$ s;  $P=0.09$ ) also showed a tendency to be greater in E. **Discussion** Data indicate that elite junior soccer players undergo greater changes in physical performance across a three year period relative to sub-elite players. This was not due to differences in initial performance nor maturity status. These findings confirm the importance of elite physical development programmes for accelerating the physical development of elite junior soccer players. **References** Mirwald, R.L., et al., (2002). ## RELATIONSHIP BETWEEN GOLF PERFORMANCE, ANTHROPOMETRY AND MUSCLE STRENGTH IN YOUNG ELITE GOLFERS

TORRES-RONDA, L.1, SÁNCHEZ-MEDINA, L.2, GONZÁLEZ-BADILLO, J.J.2

1: GIRSANE (BARCELONA, SPAIN), 2: UPO (SEVILLE, SPAIN)

**Introduction** Despite its increasing popularity, very few studies (Keogh et al., 2009; Wells et al., 2009) have tried to examine competitive golf in relation to physical characteristics. This study aimed to analyze the relationship between golf performance (determined through assessments of different parts of the game), muscle strength, anthropometrics and handicap (HCP) in young elite golfers. **Methods** Forty-four male golfers from the Golf Spanish Federation volunteered to take part in this study (age:  $18.0 \pm 7.7$  yr; HCP: -2.7 to 5.1). Subjects undertook specific golf performance assessments in a practice course: Peak Drive Ball Speed (DBS) (8 golf swings with their own driver), approach accuracy (30 shots to 100m target), putt accuracy (30 shots at 1.5m, 3m and 5m to hole). Anthropometric (sitting height, body mass, arm length and span, biacromial width) and strength measurements: 1kg and 2kg swing medicine ball throws (MB), vertical jump (CMJ), bench press (BP) and squat (SQ) progressive loading tests were performed. Peak ball speeds were determined using a Stalker ATS radar gun (Applied Concepts, Inc., USA). A linear velocity transducer (T-Force System, Ergotech, Spain) was used for isoinertial strength tests. Correlation analyses were performed using Pearson's correlation coefficient. **Results** No relationship was found between HCP, approach accuracy, putt accuracy or anthropometrics. Significant correlations ( $p<0.001$ ) were observed between HCP and best ( $r=-0.58$ ) and average ( $r=-0.61$ ) DBS, as well as between DBS and all strength variables, the most significant being: 1RM in SQ ( $r=0.64$ ) and BP ( $r=0.61$ ), mean propulsive power (Sánchez-Medina et al., 2010) with the load that elicits a 1m/s mean velocity in SQ ( $r=0.70$ ) and BP ( $r=0.68$ ). **Discussion** Our results suggest that among young amateur elite golfers (15-26 yr), DBS is more determinant to performance (HCP) than approach or putt accuracy. Hence, an increase in DBS should be considered a priority training goal. This does not mean that approach or putt training is unnecessary, but rather that an increase in these two skills alone is probably not enough to increase overall golf performance. The high correlations found between DBS and upper- and lower-body dynamic strength suggest that performing some kind of traditional resistance training, as well as developing trunk strength by means of MB throws simulating the swing movement (Keogh et al., 2009), may be beneficial to performance (DBS and HCP). However, muscle strength does not seem to be a factor for approach or putt accuracy in golf. **References** Keogh J, Marnewick MC, Maulder PS, Nortje JP, Hume PA, Bradshaw EJ (2009). *J Strength Cond Res*, 23(6), 1841-850. ## BODY MASS LOSS DURING TRAINING AND COMPETITION IN ELITE FUTSAL SPANISH PLAYERS

TUR CARBONELL, C., GONZÁLEZ-HARO, C.

SCHOOL OF MEDICINE, UNIVERSITY OF ZARAGOZA

**Introduction** It has been proposed that the level of dehydration and noot impair the exercise performance; rather, it is altered to limit the extent to which the osmolality of the brain increases (Sawka and Noakes, 2007), and the level of dehydration over -2% body mass might not impair exercise performance (Sharwood et al., 2004). The aim of this study was to determine the level of body mass loss during training and during competition of elite Futsal players. **Methods** Eleven elite Futsal players (age:  $30.1 \pm 2.8$  yrs, experience:  $11.1 \pm 3.0$  yrs, BMI:  $23.6 \pm 1.5$  yrs) of an elite Spanish soccer team drank water ad libitum in 10 consecutive training sessions (INT) and in a competition (INC). Body mass was measured before (BMBT) and after (BMAT) training and before (BMBC) and after (BMAC) competition. Body mass lost during training (BMLT) and competition (BMLC) was calculated. Comparisons between variables were made by means of a Student's t test for paired data. Statistical significance was set at  $p<0.05$ . **Results** In spite of no significant differences were shown between INT respects to INC ( $584 \pm 232$  vs.  $760 \pm 471$  mL water;  $7.6 \pm 3.0$  vs.  $9.8 \pm 6.0$  mL water·kg<sup>-1</sup>·BM<sup>-1</sup>, respectively), it was shown a decrease for both BMBT respects to BMAT ( $77.2 \pm 6.8$  vs.  $76.8 \pm 6.8$  kg,  $p<0.001$ , respectively) and BMBC respects to BMAC ( $77.9 \pm 8.2$  vs.  $76.1 \pm 7.9$  kg,  $p<0.001$ , respectively). BMLC was higher than BMLT ( $-2.3 \pm 0.8$  vs.  $-0.7 \pm 0.4$  kg,  $p<0.001$ , respectively). **Discussion** There are not studies in literature about BML of Futsal players. In this study, BML was little in training, in competition was over -2%. Edwards et al. (2007) have reported lower BML (0.7 %) associated with lower drink intake (5 mL mL·kg<sup>-1</sup>·BM<sup>-1</sup>) in active soccer players. While some authors have

reported a decrease of performance in elite soccer players associated to a small BML (2%) (Mohr et al., 2010), other authors have suggested that the level of dehydration even up to -11% BM might not impair exercise performance in the fastest endurance finishers that are often among the most dehydrated (Sharwood et al., 2004). Thus, it exists evidence that genetic factors regulating the thirst response might explain this highly individualistic response (Saunders et al., 2006). In conclusion, drinking ad libitum elite Futsal players prevents the BML during training sessions. BML during competition was moderate and may be had a little effect on increase in plasma osmolality and on exercise performance. ## PHYSICAL CHARACTERISTICS OF EXPERIENCED AND JUNIOR OPEN WHEEL RACE CAR DRIVERS

RASCHNER, C., PLATZER, H.P., PATTERSON, C.

UNIVERSITY INNSBRUCK

**Introduction** Open-wheel car racing is one of the most exciting sports. The multidimensional activity with great emphasis on physical fitness is comparable to other high performance athletes (Jacobs et al., 2002). Published scientific studies which have investigated the fitness of open-wheel race car drivers (Backman et al., 2005) or long distance car racers (Baur et al., 2006) are rare. To our knowledge, the only available fitness data from Formula One drivers is wrist strength results (Masmejean et al., 1999). The aim of this project was to analyse and compare selected fitness parameters of experienced and junior open-wheel race car drivers. **Methods** 18 open-wheel car drivers were divided into two groups. Experienced drivers (ED) consisted of 5 Formula One, 2 GP2 and 2 Formula 3 athletes whereas the juniors (JD) drove in the Formula Master, Koenig, BMW and Renault racing series. The selected performance tests included hand/foot reaction (HFR) anticipation (HFA), postural stability (PS), cyclic foot speed (CFS), isometric trunk/upper body strength (ITUS), isometric leg strength (ILS), isometric grip strength (IGS) and counter movement jump (CMJ). Group differences were analysed with a Mann Whitney U-test. The alpha level was Bonferroni adjusted to  $p=0.007$ . Results ED were older than JD and higher in CMJ and ILS ( $p=0.007$ ). Tendencies were that ED performed better in IGS ( $p=0.013$ ) and faster in CFS ( $p=0.07$ ). No differences were detected in HFR, HFA, PS, ITUS ( $p=0.1$ ). **Discussion** Motor sport teams now focus more on driver fitness. This could reduce impact injuries in crashes. Our results may indicate that ED drivers have minimally adapted over their racing careers or that JD concentrate more on physical fitness. Baur et al. (2006) reported similar fitness profiles between endurance race car drivers and physically active controls. Backman et al. (2005) showed that open-wheel car drivers differ in neuromuscular performance compared to rally drivers. Neck strength should be tested, but drivers were not prepared to give 100% effort with available isometric tests. This will be a future project. Due to the absence of race specific fitness data open-wheel car drivers would benefit from further research in this field. References Backman J, Häkkinen K, Ylinen J, Häkkinen A, Kyrölainen H. #### INFLUENCE OF REHYDRATION ON HOMOCYSTEINE LEVELS PLASMA AFTER EXERCISE

MAROTO, B., GARCÍA-GONZÁLEZ, C., VALTUEÑA, J., BENITO, P.J., MELÉNDEZ, A., GONZÁLEZ-GROSS, M.

UNIVERSIDAD POLITÉCNICA DE MADRID

**ImFINE** research group. Department of Health and Human Performance. Universidad Politécnica de Madrid (Spain). **Introduction** Homocysteine (Hcy) has been identified as a cardiovascular risk factor, whenever it reaches high levels in plasma (Boushey CJ, 1995). Some research suggests that exercise increases the levels of Hcy (Gelecek N, 2007). The aim of this study is to check the behavior of Hcy concentrations after submaximal constant exercise in heat environment, with a rehydration protocol after exercise. **Methods** We studied 10 male physically active subjects ( $23.51 \pm 1.84$  years) who performed two stable submaximal tests with a 65%  $\dot{V}O_2$  max intensity on a treadmill with a duration of 40 minutes. During the two tests temperature (30°C) and humidity (60%) were controlled. After the tests the subjects were rehydrated during two hours with water in one test (SA) and Powerade® in the other (SP). The amount of fluid intake was related to weight loss for each of the subjects. Blood samples were taken before (A), immediately after (B), one hour (C) and two hours (D) after completion of each test. We analyzed Hcy, folate and creatine Kinase (CK) levels. A minimum period of two days between both tests was established. Results Plasma Hcy concentrations increased significantly immediately after both SA and SP tests (both  $p < 0.05$ ). We also observed a statistically significant increase in plasma Hcy between A and D points in SA and SP (both  $p < 0.05$ ). During the rehydration process (B, C and D points) no significant differences ( $p > 0.05$ ) in plasma Hcy levels were found. Folate levels were statistically significant from the start of the test (A) up to two hours after completion (D) in the SA ( $p < 0.001$ ) and in the SP ( $p < 0.001$ ). A negative correlation between Hcy levels and folate in all phases of testing was found. We obtained statistically significant differences in baseline levels of CK two hours after completing the effort in the SA ( $p < 0.05$ ), while no statistically significant differences for these values in the SP were found ( $p > 0.05$ ). **Discussion** Although no significant differences were found during rehydration, the plasma Hcy level decreased slightly during this period in both tests. In the case of the sport drink (SP), a tendency of better recovery of plasma Hcy levels after exercise were found, but it did not reach the baseline levels in any case. Rehydration with a sports drink after 2 hours was more effective than hydration with water in order to restore the basal levels of CK after exercise; by contrast, water recovery process was transient. **EXERCISE AS A COUNTERMEASURE TO SLEEPINESS DURING THE NIGHT**

DAVENNE, D., LERICOLLAIS, R., GAUTHIER, A.

UNIVERSITY OF CAEN

**Introduction** Higher risk of accident is related to nocturnal activity when circadian clocks and sleep pressure increase sleepiness and decrease neurobehavioral performances. Performances assessed by simple reaction times remain stable for about 16 hr of wakefulness, and decrease thereafter to reach a dramatic impairment about 2-4 hr after the peak of melatonin (Cajochen 1999). At that time the drowsiness that occurs has been identified as the reason behind fatal many individual and industrial accidents (Mitler 1988). Studies have demonstrated the efficiency of some countermeasures such as sleeping (or napping) and the use of alertness-increasing agents (i.e. caffeine) on driving. If alertness is improved immediately following exercise (Tomprowski 2003), during the day, this potential countermeasure has never been study during the night. Furthermore, Matsumoto et al. (Matsumoto 2002) suggested that exercise during an extended period of wakefulness results in an increased risk in human error. **Methods** In this study, standardized bouts of 20 minutes of exercise at 50% of the maximal aerobic capacity of the participant has been compared with those of rest on 4 hours night-time simulator driving performance in 12 young male sedentary healthy volunteers. Exercise was performed at 0:00 and 2:35 and participants had to drive just after each of these exercise, 2 hours from 0:30 to 2:30 and 2 hours from 2:55 to 4:55. Performance criteria on driving simulator were number of inappropriate line crossing (ILC) and standard deviation of the position of the car. Self-rated sleepiness and self-rated fatigue were also recorded before and after driving. **Results** The results show that there are no statistical differences between the 2 conditions either in the number of ILC or in the standard deviation of the position of the car were compared by a one-way analysis of variance for repeated measurements (time\*treatment). An small improvement seems to occur only during the 15 min following the physical activity. **Conclusion** There is no significant improvement of nocturnal driving ability with exercise as a countermeasure to nocturnal sleepiness in young healthy volunteers. Exercise during the night might be less effective than during the day. It is also possible that the intensity of the exercise was too small to produce the expected effect. **References** Cajochen C, Khalsa SB, Wyatt JK, Czeisler CA, Dijk DJ. **THE EFFECT OF EXERCISE INDUCED DEHYDRATION ON NEUROMUSCULAR PERFORMANCE INDEPENDENT OF CORE TEMPERATURE.**

MARINO, F.E., STEWART, C.J., CANON, J., WICKHAM, J., WHYTE, D.G.2

CHARLES STURT UNIVERSITY, (2) AUSTRALIAN CATHOLIC UNIVERSITY

Dehydration may decrease neuromuscular performance (NMP) and contribute to a reduction in exercise performance outcomes. While many studies have examined the combined effect of temperature and dehydration on NMP, no studies have examined the effect of dehydration alone, independent of thermal strain. The aim of this study was to determine whether dehydration directly altered neuromuscular drive, independent of hyperthermia. Seven male participants were recruited for the study (mean  $\pm$  SD age  $23 \pm 4$  years, peak power output  $371 \pm 57$  W). Using a counterbalanced design, participants completed two performance trials one week apart. Initial testing involved neuromuscular assessments for maximum voluntary torque (MVT), voluntary activation (VA), EMG and evoked contractile properties. Participants then engaged in a dehydration exercise protocol that reduced body mass by  $\sim 4\%$ . Following this, participants rested for 2 h during which time they either replaced the volume of fluid lost or remained dehydrated. Pre-exercise values for core temperature and heart rate were re-established by the end of the rest period and NMP reassessed. The active dehydration protocol reduced body mass by  $3.8 \pm 0.5\%$ . Body mass was re-established to within  $0.2 \pm 0.6\%$  of pre-exercise values in the rehydration trial. Plasma osmolality following the recovery period was  $297.7 \pm 4.9$  and  $282.1 \pm 3.4$  Osm/l for the dehydration and rehydration trials, respectively ( $P < 0.05$ ). MVT remained unchanged throughout the dehydration and rehydration trials ( $\sim 314.5$  Nm). The VA before exercise was  $\sim 90.7\%$  for both trials and remained relatively unchanged for the dehydration ( $88.7 \pm 6.4\%$ ) and rehydration ( $90.6 \pm 6.2\%$ ) trials. Evoked peak twitch torque (Pt) increased by  $14\%$  ( $P < 0.05$ ) and  $11\%$  ( $P < 0.01$ ) following the recovery period in the dehydration trial. However, the rate of Pt increased by  $19\%$  ( $P < 0.05$ ) following the recovery in the dehydration trial compared with only  $3\%$  in the rehydration trial. These findings demonstrate the resilience of the neuromuscular system to the internal imbalances in homeostasis associated with significant active dehydration.

**PHYSIOLOGICAL RESPONSES TO CONSECUTIVE DAY TREADMILL RUNNING IN TEAM SPORT ATHLETES FOLLOWING ONE NIGHT OF SLEEP DEPRIVATION.**

MÜNDEL, T.1, SKEIN, M.2, DUFFIELD, R.2, EDGE, J.1,3

MASSEY UNIVERSITY

(1) School of Sport and Exercise, Massey University, New Zealand (2) School of Human Movement Studies, Charles Sturt University University, Australia (3) Department of Sport and Exercise, University of Auckland, New Zealand **Introduction** We have previously demonstrated that one night of sleep deprivation separating consecutive day bouts of simulated team sport exercise reduced intermittent-sprint performance, muscle glycogen content, recruitment of active muscle and increased perceptual strain when compared to a control night of habitual sleep (Skein et al., in press). The aim of the present study was to describe the physiological responses to graded, constant velocity, treadmill running performed on consecutive days separated by habitual or deprived sleep. **Methods** At  $19 \pm 1$  °C and  $54 \pm 9\%$  relative humidity, ten male team sport athletes (mean values  $\pm$  SD; Age =  $21 \pm 3$  yrs;  $\text{VO}_{2\text{max}} = 57 \pm 5$  ml/kg/min) completed 10-minute stages on a treadmill corresponding to  $60\%$  ( $9.4 \pm 0.5$  km/h),  $70\%$  ( $11.0 \pm 0.6$  km/h) and  $80\%$  ( $12.6 \pm 0.7$  km/h) velocity at  $\text{VO}_{2\text{max}}$  on consecutive days before (Day1) and after (Day2) their habitual ( $8.5 \pm 1.5$  h) or without any sleep (0 h). Measures of heart rate, expired gases, lactate and glucose were taken at the end of each stage and concentrations of bicarbonate, growth hormone, cortisol, C-reactive protein and IL-6 determined before and after the treadmill exercise. **Results** During the graded treadmill stages heart rate, minute ventilation, RER and  $\% \text{VO}_{2\text{max}}$  increased significantly with running velocity (all  $p < 0.001$ ) but values were depressed on Day2 compared to Day1 (all  $p < 0.05$ ) whilst  $\% \text{VO}_{2\text{max}}$  tended to be greater on Day2 ( $p = 0.07$ ); however, no effect of sleep deprivation was observed (all  $p > 0.43$ ). Lactate and glucose increased significantly with running velocity (both  $p < 0.01$ ) but no effects of day or sleep deprivation were observed (all  $p > 0.27$ ). Concentrations of growth hormone (increase) and bicarbonate (decrease) were different following exercise (both  $p < 0.001$ ) and C-reactive protein was higher post-exercise and on Day2 (both  $p < 0.05$ ); however, no effect of sleep deprivation was observed (all  $p > 0.22$ ). No effects of exercise, day or sleep deprivation were observed for cortisol or IL-6 (all  $p > 0.20$ ). **Conclusion** When running at constant velocities between  $\sim 9$  and  $13$  km/h ( $60\% - 80\%$  velocity at  $\text{VO}_{2\text{max}}$ ) it appears that team sport athletes can withstand the stress of one night sleep deprivation without physiological compromise, although the effects of consecutive day running are more pronounced.

### INFLUENCE OF SHIFT-WORK AND LEISURE-TIME PHYSICAL ACTIVITY ON BODY MASS INDEX, APPETITE-RELATED HORMONES AND SLEEP QUALITY

MARQUEZE, E.C.1,2, ATKINSON, G.2, ULHÔA, M.A.1, MORENO, C.R.C.1

1: SPH-USP (SÃO PAULO, BRAZIL), 2: RISES-LJMU (LIVERPOOL, UK)

**Introduction** Shift-work is associated with an increased risk of obesity, yet it is unclear whether this is due to disruption of circadian rhythms or a poor lifestyle of shift-workers (Atkinson et al., 2008). In an effort to tease out the influence of these two factors, we examined the body mass index, appetite-related hormones and sleep characteristics of shift-workers who, uniquely, were higher in terms of leisure-time physical activity (LTPA) than their day-working peers. **Methods** A cross-sectional study was undertaken on 57 male lorry drivers (age: 39.8yrs, SD=6.6), of whom 31 worked irregular shifts and 26 worked the day shift. Participants completed the International Physical Activity Questionnaire (IPAQ long-version) and were assessed for body mass index (BMI). Participants also provided a fasting blood sample for analysis of appetite-related hormones and wore an actigraphy device for seven consecutive days. **Results** Although LTPA was generally low (<150 min/week) in both groups, the irregular shift-workers were more physically active than day-workers (98.5±166.2 min/week vs 23.1±76.0 min/week,  $P=0.0027$ ). Nevertheless, the mean BMI of shift-workers was still 2 kg/m<sup>2</sup> greater than that of day-workers (28.4±3.8 kg/m<sup>2</sup> vs 26.4±3.6 kg/m<sup>2</sup>,  $P=0.0441$ ). Leptin concentration was also higher in shift-workers (5205±4181 pg/ml vs 3179±2413 pg/ml,  $P=0.0443$ ), but this was explained by the differences in BMI, more obese workers having increased leptin concentration ( $P=0.001$ ) along with decreased ghrelin concentration ( $P=0.036$ ) and shorter sleep duration ( $P=0.011$ ). This latter variable was unaffected by LTPA. Nevertheless, higher levels of LTPA were found to be generally associated with shorter sleep latency ( $P=0.042$ ). **Conclusions** Even though the shift workers in our study were more physically active in leisure time, they still had a higher BMI than day-workers. The relationships between BMI and appetite-related hormones indicate that dietary habits are more important than physical activity in moderating the health of this population of shift workers, although the established usefulness of LTPA in improving sleep onset latency is also apparent amongst shift-workers. **Reference** Atkinson G, Fullick S, Grindley C, Maclaren D. ### DIURNAL VARIATION IN MELATONIN RESPONSES TO EXERCISE: A SLEEP-CONTROLLED STUDY

MARRIN, K.1,2, DRUST, B.2, GREGSON, W.2, LEWIS, N.C.2, THOMPSON, A.2, CHESTER, N.2, ATKINSON, G.2

1. EDGE HILL UNIVERSITY 2. LIVERPOOL JOHN MOORES UNIVERSITY

**Introduction** Previously, we have identified several important relationships between the pineal hormone, melatonin (MEL) and exercise (Atkinson et al., 2003). It is emerging that exercise is a synchroniser of human circadian rhythms, possibly via the exercise-related effects on MEL and/or thermoregulation. In support of this hypothesis, we have found that increases in salivary MEL and core body temperature (Tcore), are greater following exercise in the morning compared with the afternoon (Marrin et al., 2011). Nevertheless, prior sleep, which is itself a synchroniser of human circadian rhythms, was not controlled in this previous study. Therefore, we aimed to examine diurnal variation in the MEL and thermoregulatory responses to exercise, whilst controlling the duration of sleep prior to each test. **Methods** Two trials were conducted in a counterbalanced order at 06:30h or 16:30h with sleep duration controlled at 4 h prior to each trial. Nine men (mean±SD age: 27±9y) completed 3 bouts of 10 min cycling at 60% peak power output, interspersed with 10 min rest. Salivary MEL was measured at baseline in bed, after standing, pre exercise and immediately following each 10 min bout of exercise. Tcore and skin (Tskin) temperatures were also measured. Data were analysed using factorial within-subjects general linear models. Within-subjects correlation coefficients between changes in MEL and body temperatures were also calculated (Bland and Altman, 1995). Data are described as mean±SE. **Results** On waking, MEL was 33.5±4.4 pg/ml in morning compared with 4.8±1.2 pg/ml in afternoon (mean difference = 28.7±3.6pg/ml,  $P<0.0005$ ). This diurnal difference decreased to 21-22pg/ml after standing, but there was no further change in MEL during exercise. Baseline Tcore was 37.27±0.11°C at 16:30h compared with 36.82±0.09°C at 06:30h ( $P<0.0005$ ). Exercise increased Tcore and Tskin by similar magnitudes at both times of day. The slope of the Tcore – MEL relationship was similar (3.1-3.6 pg/ml/°C) at both times of day. **Discussion** Our data indicate that the diurnal variation in MEL is robust even when prior sleep is controlled, indicating that control of this pineal hormone is largely endogenously-mediated by the human body clock. We found little change in MEL during an exercise period nor any difference in the MEL-body temperature relationship between morning and afternoon, when prior sleep is controlled, suggesting that the masking effects of sleep and exercise on MEL are interactive. **References** Atkinson G, et al. ## Invited symposia

### IS-SH05 A National Initiative to Fund Prevention Research

#### PHYSICAL ACTIVITY IN OLDER ADULTS IN THE UK: SUMMARY OF OUTCOMES FROM PROJECT OPAL

FOX, K.R.

BRISTOL UNIVERSITY

**Background** Project OPAL (Older People and Active Living) was funded through Phase 1 of the National Prevention Research Initiative. Its primary aim was to describe the physical activity levels and patterns of adults aged 70 and over using accelerometry. Associations with deprivation of area of residence, perceptions of neighbourhood walkability, convenience and attractiveness, objectively assessed physical function, body mass index, pain and mental well-being were also addressed. **Methods** Twelve primary care practices in Bristol were selected by low, medium and high deprivation, and low or high access to amenities as a sampling frame. A total of 240 adults aged 70 to 96 were recruited who were representative of the practice and national distributions of age-related BMI and level of deprivation of area of residence. Measures included 7-day accelerometry (ActigraphGT1M), the Short Physical Performance Battery, a 7-day purposes and mode of journeys log, and a range of questionnaires including the Neighbourhood Quality of Life Survey for Seniors. **Results** The final sample was 125 males (mean age 77.5 yrs) and 115 females (mean age 78.6 yrs). Physical activity levels were very low with males engag-

ing in more steps per day and moderate to vigorous (MVPA) activity than females (Davis et al., in press). Although 47% totalled over 150 minutes of MVPA per week, only 3 participants met UK recommendations because sustained bouts of at least 10 minutes rarely occurred. Lower levels of physical activity were found in areas of higher deprivation, but this was explained by differences in residents' physical function, body mass index, and frequency of journeys away from the home (Fox et al., 2011). Regardless of where people lived or their level of function, those people who managed to get and about more frequently were more active. This effect was strongest for those whose main mode of transport was walking but also for those who relied mainly on their car. Additionally, physical activity was higher in those who reported that they live close to shops and other amenities. Conclusions and implications These low levels of physical activity and associations with physical function suggest that interventions are needed to promote physical activity in order to prevent decline in function and maintain independence. AvoNet, which is a Lifelong Health and Well Being funded collaborative network arose from OPAL work and has been addressing the challenge of intervening and several proposals for programmes of delivery are currently in review. ## TRANSLATING ACUTE AND CHRONIC EVIDENCE INTO PRACTICE IN DESIGNING PHYSICAL ACTIVITY INTERVENTIONS FOR SMOKING CESSATION

TAYLOR, A.H.

EXETER UNIVERSITY

Treatments for nicotine addiction have notoriously low success rates, and exercise may increase smoking cessation (Ussher et al, 2008). Interventions have involved both structured exercise and physical activity (PA) counseling with varying reach, acceptability and effectiveness. Surveys have shown that c.22% of smokers use PA as a cessation aid (Everson et al, 2010), and 56% of NHS Stop Smoking Advisors promote PA as an aid (Everson-Hock et al, 2010a), but how best to concurrently promote physical activity and smoking cessation remains a challenge (Everson-Hock et al, 2010b). Counseling approaches can target explicit and implicit processes by which physical activity may help as an aid. Explicitly, PA has been shown, during temporary abstinence, to reduce cravings and withdrawal symptoms, ad lib smoking, and attentional bias to smoking related cues, and neuropsychological processes (Taylor et al, 2007; Janse van Rensburg et al, 2009a; 2009b). Implicitly, PA can minimise the considerable weight gain (ie, c. 5kg after 12 months) during cessation, reduce depression and anxiety and facilitate a shift from a smoker to exerciser identity (all known to be associated with relapse). Examples of recent interventions designed to aid quit attempts, or help reduce smoking, alongside existing treatments, will be presented, within the context of developing complex interventions. As an aid for quitting, an intervention (Walk-2-Quit) will be described and justified that aimed to increase the time that NHS Stop Smoking Service advisors spent on promoting physical activity, during six weekly group discussions, with a self-help guide and pedometers (Taylor et al, 2010). Building on this work, an on-going trial (Exercise Assisted Reduction then Stop) will be briefly described, targeted at 'hard to reach' smokers wishing to cut down, but not quit in the next month. The intervention, involving Health Trainers, will be described and justified, in light of what we have learned from both acute and chronic research, and also developmental applied work funded by an NPRI award. ## THE ENVIRONMENT AND CHILDREN'S PHYSICAL ACTIVITY: THE PEACH PROJECT

PAGE, A.S., COOPER, A.R.

BRISTOL UNIVERSITY

Introduction: The PEACH project (Personal and Environmental Associations with Children's Health: [www.bris.ac.uk/enhs/peach](http://www.bris.ac.uk/enhs/peach)) is a longitudinal study investigating the environmental and personal determinants of physical activity and eating behaviours in children across the transition from primary to secondary school. A cohort of 1307 final year primary school children was initially recruited from 23 UK primary schools (Year 6: aged 11.0 ± 0.4yrs) and 953 of these were followed up one year later in their first year of secondary school (Year 7: aged 12.0 ± 0.4yrs). Methods: Weekly physical activity was measured by accelerometry (Actigraph GT1M) and children wore a GPS receiver (Garmin Foretrex 201) after school to objectively record activity in different locations. Accelerometer and GPS data were recorded at 10 second epochs and were date and time matched to describe patterns of physical activity when both a GPS and accelerometer record were present (outdoors) and when there was accelerometer data only (indoors). Height (m) was measured with a stadiometer and weight (kg) was measured using digital scales (SECA), with children wearing indoor clothing, and shoes removed. Self-reported determinants of physical activity including perceptions of the environment were measured via a computerised questionnaire. Results: Compared to primary school, levels of active commuting, the proportion of young people consuming 5 portions of fruit and vegetables and the numbers eating breakfast everyday were lower at secondary school. Results of combined GPS and accelerometer data indicate that children gain more activity on their journey to school than in the school playground when they arrive and overall children recorded 41.7 ± 46.1 minutes outdoors between 3.30 pm and 8.30 pm. Children were up to 2.5 times more active outdoors than indoors (1345.8 ± 907.3 vs 508.9 ± 282.9 counts per minute). Children were also 5 times more active outside in green space compared to time spent indoors, but only 2% of monitored time was spent in green space, the majority of their time outside was not spent in green space. There was no gender difference in time spent outdoors. The most consistent determinant of physical activity was 'independent mobility', the reported frequency children were allowed to go to different destinations unsupervised by adults. Combined physical activity and sedentary data also indicated that watching TV or playing computer games for more than 2 hours a day was related to greater psychological difficulties irrespective of how active the children were. Discussion: PEACH is the largest data set to include both objectively measured location and physical activity. It is already providing important evidence that along with the social environment, both the built environment and green space matter for children's physical activity. The transition from primary to secondary school is a pivotal for the decline in activity and diet related health behaviours. The PEACH Project is funded by the National Prevention Research Initiative and the World Cancer Research Fund.

#### A CENTRAL ROLE FOR CARNITINE AVAILABILITY IN REGULATING MUSCLE FAT AND CARBOHYDRATE OXIDATION

GREENHAFF, P.

UNIVERSITY OF NOTTINGHAM

The body's carnitine pool is confined principally to skeletal muscle, where it regulates mitochondrial fatty acid translocation and ensures maintenance of a viable pool of free co-enzyme A (CoASH) during intense contraction. Oral L-carnitine feeding has been advocated as an ergogenic aid, however L-carnitine feeding per se has no impact on muscle carnitine content, fuel metabolism or exercise performance. We have demonstrated that intra-venous L-carnitine infusion (steady-state plasma [550-600]  $\mu\text{mol.l}^{-1}$ ) under insulin clamp conditions acutely increases muscle total carnitine (TC, by ~15%) in healthy male volunteers when serum insulin concentration is increased above 50 mU.l<sup>-1</sup>. More recently, we have shown this increase in muscle TC content can be achieved by combined carbohydrate and L-carnitine feeding over a 6 month period. Moreover, this increase in TC content reduced pyruvate dehydrogenase complex activation and muscle glycogen utilisation during prolonged low intensity exercise (Wall et al. 2011). Conversely, we have very recently found that muscle TC content can be markedly depleted by blocking renal carnitine retention using mildronate, which had the effect of reducing whole body fat oxidation and increasing muscle glycogen utilisation in a rodent model of obesity (Porter et al. unpublished observation). Collectively these findings point to a central role for carnitine in the regulation of muscle fuel selection at rest and during exercise, which will be discussed in the context of muscle insulin resistance and obesity. #### DIETARY PROTEIN TO AUGMENT MUSCLE HYPERTROPHY

VAN LOON, L.

MAASTRICHT UNIVERSITY MEDICAL CENTRE

Aging is accompanied by a progressive loss of skeletal muscle mass and strength, leading to the loss of functional capacity and an increased risk of developing chronic metabolic disease. The age-related loss of skeletal muscle mass is attributed to a disruption in the regulation of skeletal muscle protein turnover, resulting in an imbalance between muscle protein synthesis and degradation. As basal (fasting) muscle protein synthesis rates do not seem to differ substantially between the young and elderly, many research groups have started to focus on the muscle protein synthetic response to the main anabolic stimuli, i.e. food intake and physical activity. Recent studies suggest that the muscle protein synthetic response to food intake is blunted in the elderly. The latter is now believed to represent a key factor responsible for the age-related decline in skeletal muscle mass. Physical activity and/or exercise stimulate post-exercise muscle protein accretion in both the young and elderly. However, the latter largely depends on the timed administration of amino acids and/or protein. Prolonged resistance type exercise training represents an effective therapeutic strategy to augment skeletal muscle mass and improve functional performance in the elderly. The latter shows that the ability of the muscle protein synthetic machinery to respond to anabolic stimuli is preserved up to very old age. Though there has been much research on the impact of dietary co-intervention to maximize the impact of exercise training in young athletes, much less work has been performed in the elderly population. Research is warranted to elucidate the interaction between nutrition, exercise, and the skeletal muscle adaptive response at a more advanced age. The latter is needed to define effective strategies that will maximize the impact of exercise intervention to attenuate and/or reverse the loss of muscle mass and function with aging and, as such, support healthy aging.

#### INTERACTION OF DIET AND TRAINING ON EXERCISE RESPONSES: IMPLICATIONS FOR HEALTH AND PERFORMANCE

HAWLEY, J.

RMIT UNIVERSITY

Changes in macronutrient intake rapidly alter the concentration of blood-borne substrates and hormones, causing marked perturbations in the storage profile of skeletal muscle and other insulin-sensitive tissues. In turn, muscle energy status exerts profound effects on resting fuel metabolism and patterns of fuel utilisation during exercise as well as acute regulatory processes underlying gene expression and cell signaling. As such, these nutrient-exercise interactions have the potential to activate or inhibit many biochemical pathways with putative roles in training adaptation. Given that the greatest stimulus to any exercise-induced skeletal muscle adaptation is repeated training bouts, diet alterations for both health- and performance-driven outcomes must be tolerable and robust enough to ultimately cause an augmented adaptation that serves some functional purpose. This talk will provide state-of-the-art information from the results of contemporary human studies that have manipulated substrate availability in the face of endurance- and resistance-based training regimens, and examine the effects on both health and performance outcomes.
